CONTENTS OF VOLUME XIV

OF THE

INDIAN MEDICAL RECORD.

ORIGINAL ARTICLES:—

Abrus poisoning. A note on, By Surgeon-Major G. W. Giles, M.B., B.S. Lond., L.M.S. ...	218
Alcohol and its victims, By James Lenox-Brown, ...	138
Anchylostoma duodenale: Is it wide-spread in India, Assam and Ceylon, and is it a harmless or a harmful parasite? By Hayman Thornhill, M.D. ...	500
Bladder. Inflammation of the, By Surgeon-Captain F. J. Crawford, M.D., I.M.S. ...	504
Cardiac disease. The prognosis in, By J. E. Graham, M.D. ...	398
Cataract in the Madras Presidency of Southern India, By Surgeon-Major T. H. Pope, M.D. ...	261
Cataract. Method of operating in senile, By Assistant Surgeon Monomohun Gupta, L.M.S. ...	184
Cholera in India with special reference to pilgrimage, By Charles Banks, M.D. ...	352
Church Hygiene. A few remarks on, By V. P. Jebaretnam Pillai, C.M.S. ...	226
Climata and Malaria, By Surgeon-Major R. R. H. Moore, M.D., T.C.D., A.M.S. ...	345, 389, 445
Conservative Surgery of the Spleen: A bloodless method of partial excision performed on twenty-two dogs with twenty-one recoveries, By H. Martyn Jordan, F.R.C.S. ...	176
Cornea Diseases of the, By C. C. Caleb, M.D. ...	45, 181, 181, 312
Diphtheria. Intubation in, By W. K. Simpson, M.D. ...	508
Diseases of women a hundred years ago and to-day, By J. Morton, L.R.C.P. & S. ...	99, 222
Frauds? Who are, By W. M. Huntly, M.A., M.D., B.Sc. ...	453
Health and vice of the British Army in India. The, By W. M. Huntly, M.A., M.D., B.Sc. ...	4
Heart disease among soldiers in India, By Surgeon Major R. R. H. Moore, M.D., T.C.D., A.M.S. ...	54
Hookah, a real sanitary smoke. The Indian, By J. Morton, M.D. ...	8
How diabetic patients die and how they ought to live, By P. Le Gendre, M.D. ...	448
Hyderabad Chloroform Commission. A reply to the accusation made by Mr. Leonard Hill against the, By T. Lauder Brunton, M.D., F.R.S. ...	348
Ignorance the chief cause of disease, By Hara Kali Sen, C.M.S. ...	314
Indigenous drugs of India, By R. P. Banerji, B.A. ...	227, 355
Is Eve still to blame? By James Lenox-Brown, ...	266
Malaria parasite. On the flagellated form of the, By Surgeon-Colonel Edward Lawrie, M.B., I.M.S. ...	89
Malaria. Wind-borne, By Surgeon-Major R. R. H. Moore, M.D., T.C.D., A.M.S. ...	90
Malarial parasites. Observations on, By Surgeon-Major Ronald Ross, M.R.C.S., D.P.H., I.M.S. ...	6
Malarial poison. The localised nature of the, By Surgeon-Major R. R. H. Moore, M.D., T.C.D., A.M.S. ...	215
Medical progress, its helps and hindrances, By G. C. Savage, M.D. ...	47
Music as a Therapeutic Agent, By G. E. Claxton, L.R.C.P. & S. ...	55
Nasal polypi, By H. J. Dadysett, L.R.C.P. & S. ...	271
Necessity for special education in tropical medicine, By Patrick Manson, M.D. ...	393
Organic matters and malaria, By Surgeon-Major R. R. H. Moore, M.D., T.C.D., A.M.S. ...	173
Phrenology? Is there any truth in, By G. E. Claxton, L.R.C.P. & S. ...	7
Professional secrecy at home and abroad, By Malcolm Morris, F.R.C.S. ...	136
Puerperal fever. The nature and prevention of, By Thomas Wilson, M.D. ...	264
Puerperal eclampsia, By Kedarnath Das, M.D. ...	308
Quacks and Quackery, By G. E. Claxton, L.R.C.P. & S. ...	224
Sanitary care of the soldier by his officer. The, By Surgeon-Colonel G. J. H. Evatt, M.D., A.M.S. ...	98, 133, 493
Surgical operations performed in the South Suburban Hospital, Calcutta, By Assistant Surgeon Satish Chandra Das, M.A., M.B. ...	52
Syme. Personal reminiscences of, By Donald Maclean, M.D. ...	301
Valedictory address to the successful students of the Medical College, Madras, By R. J. Raju, C.M.S. ...	268
Water-supply and malarial fever, By Surgeon-Major R. R. H. Moore, M.D., T.C.D., A.M.S. ...	1
What operation can do for cancer of the tongue, By H. T. Butlin, F.R.C.S. ...	451
Widal's reaction in natives of India, By W. C. Brown, M.D. ...	400

A MIRROR OF PRACTICE:—

Abscess (putrid) of broad ligament causing alarming symptoms: Laparotomy. Death, By James R. Wallace, M.D., F.R.C.S. ...	228
Abscess (putrid) of broad ligament threatening peritonitis: Vaginal incision and drainage. Recovery, By James R. Wallace, M.D., F.R.C.S. ...	408
Carbonic oxide poisoning: A sad tragedy, By Assistant Surgeon H. D. Pant, L.M.S. ...	187
Carbuncle successfully treated with carbolic acid, By Arasthunker, C.M.S. ...	58
Carcinoma of the rectum: Excision: Recovery, By Arthur Neve, F.R.C.S. ...	187
Concussion and compression of the brain; hemiplegia; removal of the cause of compression: Recovery, By Ram Lal Sircar, C.M.S. ...	272

A MIRROR

OF PRACTICE—(continued).

Enormously enlarged spleen and liver due to malaria. Death : Post-mortem results, By Ram Lal Sircar, C.M.S.	187
Epidemic fever complicated with double pneumonia, By Assistant Surgeon E. S. Pushong,	402
Pyo-cyst of the uterus ; abdominal hysterectomy : recovery, By Hester Dill Russell, M.S.	9
Fractures of limbs and skull : Recovery, By Ram Dhari Sinha, L.T.M.S.	511
Gun-shot wound of breast, By Surgeon Lieutenant-Colonel A. T. Staggatt, A.M.S.	144
Gun-shot wounds. Notes on, By Surgeon-Captain J. M. Crawford, I.M.S.	356
Hæmorrhage. A strange case of, By John V. James, D.G.M.C.	317
Hæmatemesis. Fatal uncontrollable, By Assistant Surgeon Jaikishan Das,	230
Homicidal cut-throat, vertically destroying entire larynx and a portion of trachea : Recovery, By Ram Lal Sircar, C.M.S.	230
Infantile convulsions. A typical case of, By Assistant Surgeon M. A. Curry,	272
Intestinal obstruction. Three cases of acute, By W. M. Huntly, M.A., M.D.	357
Laparotomy with removal of both fallopian tubes for acute suppurative peritonitis supervening upon double gonorrhœa, By James R. Wallace, M.D., F.R.C.S.	10
Lightning stroke at Darjiling: Recovery. Three cases of, By Surgeon-Major R. R. H. Moore, M.D., T.C.D., A.M.S.	508
Lithotripsy. Peculiar double stone case : one stone encysted in upper and anterior wall of bladder. Successful, By W. M. Huntly, M.A., M.D.	510
Liver abscess. A case pointing to the advantage of early aspiration in doubtful cases of, By Surgeon-Major R. R. H. Moore, M.D., T.C.D., A.M.S.	102
Liver abscess ; early incision and drainage : Recovery, By Surgeon-Major H. R. Woolbert, I.M.S.	142
Magnesium sulphate in dysentery, By J. Morton, L.R.C.P. & S.	511
Morbid growths of conjunctival tissue; operation : Recovery, By Jaganath, L.M.S.	512
Mutilation of lower leg : amputation ; recovery, By John V. James, D.G.M.C.	359
Naso-pharyngeal polypus, successfully removed. Reported by Amrik Singh,	229
Naso-pharyngeal polypus, successfully removed, By Surgeon Lieutenant-Colonel W. H. Henderson, F.R.C.S.	456
Nasal (traumatic) disfigurement, with obstructive deflexion of the septum, cured by forcible reposition and a plastic operation, By James R. Wallace, M.D., F.R.C.S.	103
Nasal deformity and obstruction due to a large rhinolith. By Assistant Surgeon H. D. Pant, L.M.S.	188
Oleander poisoning. Notes on a case of, By Assistant Surgeon H. D. Pant, L.M.S.	359
Otorrhœa followed by brain abscess and death. Chronic, By N. C. Chatterjee, L.M.S.	143
Ovarian dropsy : Ovariectomy : Recovery, By Assistant Surgeon T. M. Shah, L.M.S.	317
Parasitic malarial fever. Recovery, By Surgeon-Captain M. O'Halloran, A.M.S.	57
Plague bubo in sarcomatous glands, By Surgeon-Captain B. H. F. Leumann, M.B.	57
Plague treated on ordinary principles. A case of true, By John E. Panioty, L.R.O.P. & S.	509
Polionyelitis. Case of acute, anterior, By V. Dinshaw, G.H.M.S.	273
Pulmonary abscess treated as liver abscess bursting into the lung, By R. G. Kar, L.R.C.P. & S. and reported by Beni Madhav Basu, C.M.S.	457
Rabies. A clinical picture of, By Arthur Sweeny, M.D.	58
Spinal paralysis due to deep sea diving, By Assistant Surgeon G. R. Gaudoin, M.D.	358
Spontaneous amputation of both lower extremities in a new born infant, By Surgeon-Captain C. Duer, I.M.S.	9
Symphysiotomy. Delivery by forceps, By T. M. Shah, L.M.S.	316
Unintelligent versus intelligent midwifery. Notes of a case, By Edith A. Huntley, M.D.	456
Vomiting for eighteen years, abdominal section : Cure, By H. G. H. Naylor, L.R.C.P. & S.	101
Wound of the abdomen. Unusual case of penetrating, By Surgeon-Captain C. Duer, I.M.S.	273

WATER SUPPLY AND MALARIAL FEVER.

By R. R. H. MORGAN, M.D., F.R.C.P.

Surgeon-Major, A. M. S.

WITH little or no change since the days of PARKES, we find English writers constantly harping upon the same old theme that the poison of malarial fever may be conveyed into the system by means of drinking water.

Articles advocating this view frequently crop up in the medical journals, and in some of the most recent works on Hygiene and Public Health published in England, as in Thresh's Water and Water Supplies, and others I need not specify, the writers are not ashamed to dolefully repeat the same old tales that have gone the round for years; to the annoyance and irritation of the reader they trot out these faded old Rosinantes which have become spavined and halt and blind from all the criticisms that have been hurled at them, and are now quite unequal to the load they are expected to bear.

The remarkable thing is that no fresh evidence of any kind is ever brought forward; one or two modern instances would make a pleasant change, but the writers prefer antiquity, and treat us to the well barked quotation from HIPPOCRATES, now HIPPOCRATES is well enough, but I am afraid the fathers of medicine do not get much respect from their sons of this generation, unless by chance their opinions happen to coincide.

When HIPPOCRATES said that the spleens of those who drink the water of marshes become enlarged and hard, he doubtless said what was quite true, but it may be presumed that the people who drank marsh water lived in marshes, and under such conditions enlarged spleens are common enough, though this is no evidence that the water is the cause.

Of the same nature is the statement made to PARKES by the villagers of Troy "that those who drank marsh water had fever at all times of the year, while those who drank pure water only, got ague during the late summer and autumn months." It is not probable that people holding such a belief ever drank marsh water from choice; those who drank it lived in marshes where they could get no other water.

The most famous case brought forward by the water theorists is that reported by BOUDIN, which has made the modern *Argo* almost as celebrated as its classical predecessor. Of this PARKES says: "The evidence seems here as nearly complete as could be wished," and with this case I fancy most others will stand or fall.

"BOUDIN's account is as follows: 'In the month of July 1884 the Sardinian ship *Argo* left Bône with 190 healthy soldiers, when she arrived at the lazaret at Marseilles, thirteen men had died in this short passage and been thrown into the sea, 98 men left at the lazaret presenting the most unequivocal signs of malarial infection in all its forms and in all its types, and attaining in some the greatest degree of gravity, or as some would say, perniciousness.'

"While these soldiers were attacked with fever, choleraic, epileptic, comatose, tetanic and other varieties which

attended, as by enchantment, 50 large doses of quinine, the crew of the ship in striking contrast preserved perfect health; but what could be the cause of such a difference amongst individuals, who apparently at least had been exposed to identically the same influence?"

"Enquiry showed that the crew had preserved their health they owed it to the purity of the water that was provided for their special use; while the soldiers were forced to drink a water drawn from a marshy place close to Bône, and embarked in haste at the last moment."

"The soldiers who escaped were some who, having saved a little money, were able to buy water from the Sardinian sailors."

"This fact demonstrated in a peremptory manner, that marshy matter in the liquid as well as in the gaseous state, when absorbed by the gastro-intestinal as well as by the bronchial mucous membrane can cause malarial fever."

In an extremely able and interesting article published in the *Annales d'Hygiène Publique*, April 1872, p. 241, under the title "De l'ignition des Eaux Marécageuses," M. COLIN tells us how, in looking over some old records, he came across the following, which at once arrested his attention from its close resemblance to the story told by BOUDIN, the paper referred to is by Dr. LEONARD, and will be found in *Recueil de Mémoires de Médecine Militaire* t. 38, p. 226.

Dr. LEONARD says: "A part of the facts which follow I owe to M. DUMOUX, Surgeon Aide-Major of the 3rd Bn. 55 of the line. In the month of August 1834, what remained in Africa of the old regiment received an order to leave Bône and return to France. Merchant vessels were chartered for transport; amongst others I engaged a Neapolitan ship which took 125 men on board."

"During the passage of eighteen days, salt provisions had to be used owing to the scarcity of fresh water which, from being stored in old casks, quickly became bad."

"Under these insanitary conditions disease of a serious nature set in, symptoms of typhoid fever appeared, and about thirty of the soldiers died either on board ship or in the lazaret at Marseilles."

These two stories are so similar that, on reading them, the idea at once suggests itself that these both refer to the same event.

There are certain differences it is true, one ship left Bône in July, the other in August, 1834; one was a Sardinian, the other a Neapolitan; one had 125 men on board, the other 190; but it is easy to attach too much weight to these; the last two are very trifling, and only such as two different narrators might easily have made. With regard to the first, as the day of the month is not given in either case, it is open to assumption that the exact date was near the end of July, or beginning of August, in which case the difference is not very great.

The other facts recorded lend themselves to the above inference, though unfortunately none of them tally in such a way as to make the inference a certainty.

Perhaps the most curious thing, on the supposition that we are dealing with two distinct recurrences is, that neither writer makes any allusion to the experiences of the other, though the sick were landed at the same place, the lazaret at Marseilles, at a short interval, and a con-

Several reports of malarial fever have been received at the time owing to the very common, if not universal, nature of the fever.

Whether the truth may be, Dr. OLM, who was in position to judge, has, after a careful consideration of all the facts and probabilities, come to the conclusion that the two questions are only two different aspects of the same thing. As to the nature of the sickness which appeared with such fatal results, he adheres to the opinion of BLANC that it was of malarial origin, and supports the explanation given by Dr. LACHMAN.

His views on this subject have been generally adopted both in France and Germany.

KUNZ and KUNZ say: "Grave objections have been formulated against BLANC's interpretation of this matter by M. GILLES, who is inclined to regard the occurrence as an outbreak of typhoid fever, such as is not uncommonly seen in over-crowded ships, and we have no difficulty in recognizing the legitimacy of his doubts."

It is certainly a curious thing that this important contribution of M. GILLES to the subject, has been so long overlooked by English writers, who continue their adherence to BLANC's very doubtful opinions long after they have been repudiated by his own countrymen.

Another case which is frequently quoted in support of the theory that malarial fever may be caused by drinking water is that of Dr. BLANC and Mr. PRIDBAUX. PARKES states that Dr. BLANC in his papers on "Abyssinia" mentions that on the march from Massowah to the highlands, Mr. PRIDBAUX and himself, who drank water only in the form of tea or coffee, entirely escaped fever; while the others who were less careful suffered; and as Dr. BLANC believes from the water.

Anyone who takes the trouble to read Dr. BLANC's original paper in the *British Medical Journal* of April 1889, will be surprised to find how little there is in it to bear out the construction put upon it by PARKES.

In the first place Dr. BLANC never made the statement that he and Mr. PRIDBAUX derived their immunity from malarial fever to the fact that they never drank water, except in the form of tea or coffee; or that the others got malarial fever because they did not observe this precaution; though such is the inference that most readers would draw from the above quotation.

Dr. BLANC and Mr. PRIDBAUX displayed great wisdom and foresight in the means they adopted to ward off sickness of all kinds; everything was thought of, nothing left to chance, and the result was that they succeeded in traversing an unhealthy part of Abyssinia at an unhealthy time of the year, without paying any penalty in the way of sickness.

Their experiences show how malaria may be avoided, even in some of its worst haunts, and afford an admirable lesson to all travellers in similar circumstances; while Dr. BLANC's paper may be looked upon as a summary of almost all that is known about malarial prophylaxis.

"Each of us," Dr. BLANC says, "had taken with him a folding, very light, iron bedstead, and we made it a rule never to sleep on the bare ground. Again, he says, "everyone slept in the open air wrapped up, like and all in a good thick blanket." And the following extract

shows plainly enough that he was not very generally to other things, as well as the precautions they took about their water: "Dew often fell so heavily towards the morning in the Sudan, that everything around us was wet, and had we neglected our blankets, we would have been alone to blame had we caught chills and feverish."

They exercised the greatest care in the selection of their camping ground, always avoiding low-lying damp places; at night large fires were always kept up, and, needless to add their clothing was the subject of special attention.

To all these measures there can be no doubt that they owed their unimpaired health; but the deduction that it was due solely to the precautions they took regarding their drinking water is not justifiable.

So much for the immunity enjoyed by Dr. BLANC and Mr. PRIDBAUX, now for the statement that the others suffered because they were less careful; the inference being that they suffered from malarial fever because they drank impure, polluted water.

There is one point in Dr. BLANC's narrative which makes it impossible to draw any conclusion between it, regarding the connection between malarial fever and drinking water, and makes any conclusions so drawn valueless.

Dr. BLANC, curious as it may seem, draws no distinction between diarrhoea, dysentery and malarial fever, but classes them all as malarious diseases, so that when he imputes sickness to the drinking water, it is impossible to decide which form of sickness he refers to.

"All our servants," he says, "suffered from some malarial sickness or other, they suffered severely from fever, diarrhoea, and dysentery."

He had to carry his drinking water long distances, and he found that "if the skins are not properly prepared, there soon remains out of several gallons but a few pints of a thick dirty fluid, as disagreeable to the taste as it is unwholesome."

Under such circumstances, and holding the views he did regarding malarious diseases, it is not surprising that he laid great stress upon the importance of a pure water supply when travelling in malarious countries, but no sufficient evidence appears for making him a sponsor for the waterborne theory of malarial fever.

Another case that has come to be regarded as almost classical is that of TILBURY last recorded by Brigade-Surgeon FAUCON.

In that case it appears that the "Artillery" quartered at Tilbury Fort generally suffered, more or less from ague, while the people at the Railway Station and the coast guards and their families in the ship lying just outside the fort never suffered from malarial poisoning." In the report under consideration this difference was attributed to the fact of a different water supply being used.

The artillery got their water from tanks which were underground and exposed to seepage from the surrounding salt marsh, while the other people got theirs from a spring at the military station.

It is certainly a remarkable thing that during the time over which the observations extended, the nature of ague

...the water used by the...

Date	Admissions	Deaths	Water used	Remarks
1873— July to June	108	24	23	Barrack tanks. Water unpurified.
1874— July to June	108	15	11-4	Do do. Filter constructed.
1875-1876— Jan. to July	81	10	1-1	Spring at Ball- top Station. Tanks under re- pair.
1876-1877— Nov. to March	52	4	7-4	Barrack tanks. Water purified.

It will be observed from the above table that when the railway spring water was used, there was only one case of ague, which the footnote suggests was not contracted at Tilly.

When the tanks were repaired and the water purified, the percentage of admissions was only 7.6, while before these works were carried out it was 33 per cent., and a considerable improvement followed the construction of filters in 1873, which brought the percentage down to 11.8.

This case, formidable as it appears, is open to several serious objections.

With one exception we are not told where the Batteries stationed at the Fort had previously served, the exception is the Battery which was there in 1875, which had just returned from Gibraltar.

Regarding the years 1872-1873 and 1874, there is nothing to show whether we are dealing with three distinct bodies of men, or with only one.

I don't happen to know if the Batteries remained at the Fort throughout the whole year, or if it was only occupied during the months in which the observations were taken, but this point does not materially affect the criticisms I have to offer.

There is, of course, nothing surprising in the part of soldiers coming from abroad suffering more from ague than people who have never left England, and the omission to mention whether or not these men had been abroad is certainly unfortunate.

But the shakiest part of this case is the season of the year in which the observations were made.

When ague was a prevalent disease in England, the season for its appearance was late summer and autumn, not mid winter, and a person who stated that he got ague for the first time in January, though he had never left the country, would be liable, to put it mildly, to have his veracity seriously impugned. Yet that is the month in which one of the recorded cases appeared.

In that matter the French are much more methodical than we are, and divide their cases into those of primary invasion and relapse, and they fully recognise that the cases which crop up in considerable numbers in the spring almost invariably belong to the latter class.

It is quite impossible to believe that the poison of malarial has ever been native in England during the winter months, and the fact of a man getting ague at that time is so great an anomaly, so that we are driven to the

conclusion, however, that, in cases that occurred at Tilly Fort, were not ague, that they had really been contracted elsewhere, and that the poison was got fresh in the water, or something else. Supposing the same Battery had been at Tilly Fort for the first three years after return from abroad, the killing-off in the amount of ague year by year would be only gradual.

Supposing they were all different batteries, the number of deaths to be considered would be so numerous, that, quite putting aside the smallness of the numbers and the shortness of the periods referred to, it would be quite impossible to draw accurate conclusions from their statistics. These three examples I have thought well to consider in detail, others may be quoted more summarily.

On the authority of M. Chomatin, a French statesman, that in Marseilles governmental fever, formerly unknown, have made their appearance since the (water) supply to the city has been taken from the coast of Marseilles. M. Duvivier has exploded this idea, and has shown that the fever in question are due to the embryos becoming unfertilized from leakage from this same coast. BACON¹ is an interesting paper published in 1873 states that he found a large quantity of organic matter in snow at Camp Douglas in the Rocky Mountains, and advanced the novel theory that organic matter was blown up from malarious regions, precipitated from the atmosphere by means of falling snow, that it then infected the water supply and caused malarial fever.

This idea has been completely refuted by the stringent criticisms of Dr. Woodward,² to which any one interested in it might refer.

A very strong case was made out for water infection by Mr. BERTINGTON³ in 1856, and in 1864 similar evidence was given by Mr. WHALLEY,⁴ also of the Indian Civil Service.

These cases are difficult to criticize, if there was really any truth in the conclusions arrived at by these gentlemen, one would have expected the results to have been cumulative, and many more instances of the same nature to have been recorded since, which would have placed the matter beyond doubt. Still, however, is not the case, and like good wine, these stories do not improve by keeping; they are now indeed somewhat stale.

Regarding Mr. BILLINGTON's case PARKES says: "Nothing can well be stronger than the positive and negative evidence brought forward in this paper."

Here we are presented with instances of fever disappearing from native villages simultaneously with the digging of wells, the inference being that the disappearance of the disease was due to the introduction of a pure water supply. This case may, I think, be compared with that recorded by Mr. BLOWEN of Bedford, also mentioned by PARKES, "where the ague of a village (in England) had been much lessened by digging wells."

The effects of drainage in diminishing or removing malarial in many climates is well known, and there can be no doubt that wells have, to a certain extent, a similar effect in lowering the level of the sub-soil water; perhaps this may be the explanation here.

⁷ ...the water used by the...

In the same way it was observed, that there was a very considerable reduction in the death-rate from phthisis in many towns in England, after the introduction of a regular system of sewers; this, which at first appeared to be the result of improved methods of ventilation, is now universally regarded as due to the lowering of the level of the sub-soil water, caused by the channels dug for the sewers adding to land drains. I mention this merely to show how easily errors may arise in observations of this and kindred kinds.

The great objection to most of the instances in which water is alleged to have caused malarial fever, is that they have occurred in places where the disease is endemic, and where it is almost impossible to demonstrate positively that the poison did not enter the system through the medium of air. An *Annals* very justly says, in the paper before alluded to, "It is necessary to have cases where the infected person was exposed to only one of these causes, as for instance persons on board ship or in a residence sufficiently elevated or removed from marshy influence, yet drinking a water of marshy origin, or of persons living in an unhealthy district remaining free from disease through drinking a pure water."

The *Argo* is about the only case ever recorded which fulfilled these conditions and it has been discredited. If malaria could be conveyed (note the system) by drinking water, outbreaks of the disease must have frequently been reported from ships which are obliged to take in water in all parts of the world; and do so with impunity on the West Coast of Africa.

That Surgeon COPPINGER says:—"The statistical returns of the navy show no improvement in the amount of malarial fever in the last thirty years, while great improvements have taken place in the character of the water supply."

If negative evidence were of any value in disproving the water theory, numberless instances could be quoted to show that marshy water and water charged with decaying organic matter, have been used over and over again without causing fever, but such cases are evidently useless for the supporters of the water theory, as far as I am aware, maintain merely that water is an occasional medium, not the sole medium by which the poison of malarial fever is conveyed into the system.

It is very difficult to understand how it is that the idea still holds its ground, considering how little there is to be said in support of it, unless it is due to the great influence of *PARMEY*; for it is evident from his work that the water theory was a favorite one with him.

It is important to note that the theory has been entirely given up in France by *COLIN*, *KELCH* and *KUNIS*, and in Germany by *HERTZ*.

It is necessary to add that a move has recently been made to survive it in connection with *LAVERRAN*'s parasite.

*LAVERRAN** expresses himself in favor of it, and *BARNES*† says: "According to my latest investigations, it appears that the parasites of malaria pass through one stage of their development in water."

VANDYKE CARTER‡ has also expressed his opinion that the infection is caused by drinking water. These statements must, however, rest on their own merits, for their authors have brought us forward no definite evidence of their truth.

THE HEALTH AND VICE OF THE BRITISH ARMY IN INDIA.

By WM. HUNTLY, M.A., M.D., F.R.C.,
Nasserchead.

SOME time ago, a medical brother remarked to me that in the native state town in which his work lay, venereal disease was rife, and in return enquired into my experience. While he spoke, my memory went back to a visit paid some years before to that same town and the sights I then saw. I was wondering if it could be worse; and, with this picture in my mind, casually replied that I did not expect there was as much in my place. Suddenly I was roused out of my abstraction by the wild comment that, of course, the better condition was due to the presence of the old regulations keeping it down, and in a moment I saw I was in a trap. If I had replied that venereal was increased, the retort was ready, namely, the increase was due to stoppage of regulations. This is the kind of medical argument which bears force at the present time. Whichever way an answer is given, the regulations have their appraisers, and to themselves their logic is impeccable. I'm afraid I again fell into a brown study as to the amount of moral obliquity present in my brother medical's brain shown by the indecent haste to give credit to these same vice-propagating rules. But the Indian Government is to find out that it has never given a more forcible impetus to the formation and growth not only in England, but in India, of a sound moral opinion on this subject, and that this opinion is extending beyond Christian men to the minds of our native medical brethren of either professed faiths. Our Government in India look on it only as a government question, concerning itself with their soldiers, and doubtless feels surprised that outsiders should touch it. They are to be rudely awakened up to see that it is a world-wide question and a world deep one, dragging not only our soldiers down to the deepest hell, if immorally answered, but bringing nearer and nearer the question of the several relations of mankind, irrespective of race. Faced honestly and answered truthfully by any nation means for that nation honor, faced dishonestly and answered evasively, and the result with mathematical precision is degradation.

What every lover of truth and Britain's honor desires to hear is this: not what is the wording of the new enactments, but rather how does the Indian Government intend to face and answer the question.

To inform our readers of the various legislative steps which led to the present situation, I beg to submit a somewhat lengthy quotation:—

THE SITUATION.

For nearly a quarter of a century the war against State regulation of vice was waged in this (England) country. During that long period the progress of the views we hold was steady and continuous. The end was that the whole system of regulation, whether in England or in India, was condemned by the unanimous vote of Parliament. Indeed, it was condemned by three separate Parliaments. First, by a resolution of the House of Commons in 1868, by an overwhelming majority slowly and gradually created by the force of conviction. Next, in 1886, in another Parliament, by an Act passed without opposition. And in the third place by a third Parliament in 1889 by a unanimous vote of the House of Commons. These are few names which have been reiterated and continuously successful in three successive Houses of Commons, elected under very varying conditions.

* *Hygiene and Diseases of Hot Climates*, (Basil) 1895.
† *Talks and Papers*, London, p. 404, 405.
‡ *British Medical Journal*, 7th August 1894, p. 793.
§ *Scientific Notes*, by Med. Off. A. of India Pt. II, 1895.

That move was due to the already shown consequence of all lines of argument in the condemnation of Regulation. From the point of view of morality it stood condemned, from that of justice and equality, from that of lifted womanhood and from the gradual and cumulative consent of all Christian churches, so how then from the point of view of Science itself so well upheld by Sir JAMES HENRIE, and Dr. WYVING. To this condemnation was added that of the great scientific philosophers, JOHN STUART MILL, DE LAVELAYE, and HERBERT SPENCER, all of whom have been always active opponents of Regulation. There was then no chance or snatch element in the Repeal which was obtained. It was built up on a solid and wide base.

The resolutions of Parliament were obeyed in England, but they were not obeyed in India. There lay the difference. In the distant cantonments medical and military faddists held their old course, and could open their minds neither to new ideas nor to a changed situation. It became evident in 1898 that something stronger was necessary for India than the mere expression of the House of Commons' wish, and in consequence, after considerable discussion, an Act of the Indian Government was passed in 1898 which rendered illegal the practices which had been condemned by the extremely important weight of authority which we have just quoted. That Act then was no snatch measure; it was the deliberate embodiment at the instance of the Parliament of this country, of the firm and solid convictions worked out by the contest and growth of quarter of a century. It is that Act which the Indian Government, with the sanction of Lord GEORGE HAMILTON, have repealed, hurriedly without one word of discussion, acting on a manufactured panic. Any Government which had the least knowledge of, or respect for, the past would have replied to the Indian demand for something to be done—"Yes, do something, but remember the Act of 1898, the accumulated result of so much enquiry." But, on the contrary, what Lord GEORGE HAMILTON replied was: "You may repeal that Act, and thereby wipe out the lessons of the past." And for that legislative record be substituted merely his own advice not to do the things it forbade—advice which has never been found yet to weigh with the Indian Government. In addition to this, new regulations have been made which themselves amount to the re-adoption of the system, and which, viewed in the light of the repeal of the Act of 1898, actually become the old system over again.

To make the matter clear as noon-day, the Act which is to be repealed or has been already repealed by the permission of the Secretary of State for India is as follows.—It forbade "any regulation enjoining or permitting any compulsory or periodical examination of any woman for the purpose of ascertaining whether she is or is not suffering from any venereal disease or is or is not fit for prostitution, or any regulation for the licensing or special registration of prostitutes or giving legal sanction to the practice of prostitution in any cantonment."

In repealing this the door is open to the gradual or rapid introduction of any so-called preventive measures, and thus immoral practices are left hang on the opinion of a very few out here in India, these few being free from any higher authority and responsible to none.

I have written that these regulations hang "on the opinion of a very few out here in India." It is well known that it is a mere opinion, and no definite judgment spontaneously emerging and deduced from experience. It has neither sound medical nor sound moral grounds on which to go. I refer to prostitution regulation.

In reference to this "opinion," which has been thrown back in the faces of those medical men who have promulgated an unfit medicine to justify itself, and which has received fresh condemnation by the action of General GOUGHMAN, in Natal, who by choosing the better way has demonstrated that in Natal without regulation disease

was only half what it was in Cape Town with regulation; in reference to this I re-read the other day in that old book "The Pilgrim's Progress" words that well apply to the present situation.

Great Heart thus says:—"Because good men heretofore have sinned of infirmity, therefore he, 'Self-will,' had allowance to do it of a presumptuous mind; or if, because a child by the blast of the wind, or for that it stumbled at a stone, fell down, and defiled itself in mire therefore he might wilfully lie down and wallow like a bear therein."

Self-will says:—"To do this by way of opinion, seems abundantly more honest than to do it, and yet hold contrary to it in opinion."

Great Heart replies:—"A very wicked answer; for though to let loose the bridle to lust, while our opinions are against such things is bad; yet to sin and plead a toleration so to do is worse. The one stumbles beholders accidentally, the other leads them into the same."

Old JOHN BUNYAN's spiritual insight supplied the answer to the present situation long ere it arose.

Now-a-days the term prostitution does not seem to convey to many minds the horrible nature of the sin it represents, and regulated prostitution seems to represent something cleanly.

By JOSEPHINE E. BUTLER it is called "The abomination of desolations" which, to quote another, transforms the British army into an "ante-chamber to the brothel." *Such is the system in any form and in its brightest prospect!* Those who approve it justify themselves on what are named patriotic and national grounds. Such a policy is Machiavellian in principle, and such patriotism lends fresh proof to the truth of Dr. JOHNSON's definition of patriotism, that it is the last refuge of a scoundrel. There is so much medical proof, not only in the history of the past regulations, but from the records of other European nations, that no Government medical officer can stand up and justify them openly. It is all a perhaps, all an opinion that there may be a few less cases in hospital, a wretched, despairing, God-condemned position. In the *Indian Medical Record* a soldier not long ago wrote that we would require to start again with a new army of soldiers and a new army of prostitutes, and then we would not succeed to gain the end proposed. We have been informed that Government does not intend to carry on the old regulations, and what is going to be tried is this, that the soldier who presents himself with the disease has to point out the woman from whom infection has been caught, and that this woman must submit to treatment or be expelled from the cantonment.

As we expected. The soldier dreams that those who are not expelled are clean and thanking the Government for trying to make matters safe for him goes on his blind course feeling that he has Government with him. It would be much more effective if Government ordered to be printed in large letters and hung in every mess-room canteen and barracks the simple words of the seventh commandment—"Thou shalt not commit adultery," and let these words print themselves into soldier and officer alike. These who are at the head of affairs do not see how every section of the army is being degraded by the position they actually have taken up on this question. Every one cries out that it is for the soldier in India, the

private soldier, that the soldier's master, as he is called, is the master of the state of affairs in India. But the soldier is the soldier in India; he is not placed with the soldiers who have even suggested the idea of the state. The soldiers should be kept and taught to keep, and the officers need not be surprised should they find that the soldiers are not so satisfied.

What is the officer's duty better than that they should talk to the soldiers? said a soldier to me the other day smarting under a letter from his home father. And what more he could not be printed here. There is no officer or man who is too high to be influenced to his hurt by an immoral opinion and by the presence in our midst of regulars who, conscience vice. These best love their brethren and their country who seek their good and their true moral well-being. It is false to say we can't get out of this 4th by moral means, and it is true to affirm that we shall never get out of it by tampering or tampering with men. There is a world of difference in renewing these regulations at the present time. We can condone the actions of medical men who thought that on purely medical grounds they were saving men; that day has gone for ever. The regulations are not even sanitarially a safe-guard, and men who propose them go forward, either blinking the facts or ignoring them. When will men learn that what God has judged immoral can never be healthy. For our nation it means only shame and worse.

OBSERVATIONS ON MALARIA PARASITES: MADE IN SECUNDERABAD, DECCAN.*

By SURESH-MAJOR RONALD ROSE, M.R.C.S., D.P.H., I. M. S.
Secunderabad.

The following observations may be of interest in connection with certain statements which have been made of late respecting the malarial parasite, such, for instance, as its scarcity in India and the difficulty of finding it.

From 28th April to 8th September 1895 (that is from the middle of the hot weather till the middle of the rains) the writer examined microscopically the blood of all the fever cases which he found in the station, namely, such cases only as are returned under the heads of malarial and simple continued fever. The large majority of the cases occurred in men of the writer's regiment stationed in a malarious quarter of the large station of Secunderabad; all were natives or half-castes, and nearly all were fresh infections. It is proper to state here that the writer, owing to pre-occupation with other microscopical work at the time, did by no means profess to make any exhaustive examination of the blood in all cases; he used the simple method given by LAYMAN and MANNABERG, and detailed by PATRICK MASON; he examined all cases once, but many cases only once, and it should be added many cases (especially when they were coming in at the rate of 4 or 5 daily) very hastily. Out of 112 cases the parasites of malaria were found in 66 or 58.5 per cent, namely, 20 spring tertians, 1 quartan, 23 fresh summer-autumns, 6 cases of doubtful type, 5 mixed tertians and summer-autumns, and 2 of doubtful species. It must be remembered that this 58.5 per cent. of positive

cases is estimated from a total of 112 cases, and not from the seasonal fevers which the writer has seen, and which he thought to be the malarial fevers of the station.

The monthly examination was as follows: April (hot weather), 4 crescents only, all mixed, 2 young tertians, negative. May (hot weather), 1 crescent, 1 spring tertian, 2 doubtful species, 4 negative. June (rain), 1 on 19th, 1 crescent, 2 quartans, 2 doubtful species, 12 negative (many possibly summer-autumns), July (rain), 12 spring tertians, 13 summer-autumns, 2 mixed, 1 doubtful, 10 negative. August (rain), 11 spring tertians, 18 summer-autumns, 2 mixed, 1 doubtful, 30 negative. September (to 8th rains), 1 spring tertian, 1 summer-autumn.

Out of the 45 negative cases it is almost certain that a large number were cases in which the parasite had been overlooked; 5 of them, however (though difficult to judge by the symptoms), still gave negative results after repeated examinations of the blood. Of the whole number of cases not more than 2 could be diagnosed with any certainty on a study of chart, symptoms, and blood, as being non-malarial fevers; of these one was a three weeks' fever, and the other probably of a typhoid nature.

The great majority of cases, including such fevers as the writer had formerly thought to be febriculous, were either at once shown by the microscope to be malarial or judged to be so by a comparison of them with the admittedly positive cases. The various species of the parasites agreed closely with the descriptions of MANNABERG and others; so that there is every reason for thinking that, as JAOMBIE has already pointed out, the Italian classification holds also for India. The quartan, tertian and summer-autumn parasites differed markedly from each other; but, contrary to a statement of MANNABERG, the young parasites of the two former varieties exhibited often an undoubted ring form, though the rings were much larger than those of the summer-autumn parasites. In these varieties the small rings and amoeboid forms were, in the majority of cases, the only parasites seen at first but were plentiful and easily found; occasionally, however, larger pigmented forms and "honey" corpuscles were plentiful, and of course crescents, with the flagellate evolution form, set in as usual after the febrile period. The spring-tertians were generally double and afforded, like the two quartans, a beautiful series of specimens. In the three mixed cases there were the small summer-autumn rings and amoebae, in addition to the larger spring forms. It is an interesting point that the summer-autumn fevers set in after mid-summer; but it is impossible to state on one year's experience whether the seasonal variations found in Italy are also found in India; the earliest cases discovered in April and May were all old infections. With regard to the type of fever, it may be remarked that with the natives of India the summer-autumn parasites do not appear to occasion much more severe illness than do the other forms, rather the contrary perhaps. It is interesting to note that in several persons both quartans and spring tertians occurred, attaining the double type, so that MANNABERG's theory respecting the function of parasites can scarcely be upheld. In the large majority of attacks the fever was benign, but in 2 or 3 it was accompanied by great prostration, and in one with delirium and other grave symptoms. Two children were also attacked with

* Adapted from the author's report to the Government.

...one of them... the only... of the... It was... that in... cases of the... the... were... in... all in the... blood;... of... only three... were... and... at different... Spleenic blood was not made use of.

In almost all the specimens in which the parasite, whether spring-autumn, quarter, or summer-autumn, was found as all it was found within one or two minutes of bringing the microscope to a focus. Experience showed that quickness of microscope diagnosis depends solely on knowing how to make a specimen and what part of it to examine first: speaking generally, the smaller the parasite form looked for the shallower must be the film of blood examined. For quick working by one familiar with the subject the only rules of technique which appear to be essential are to obtain a free (not squeezed-out) drop of blood from the finger, and to blow upon the slide in order to remove incessantly falling dust immediately before imposing the charged cover-glass. In large numbers of specimens diagnosis was effected almost immediately. The smallest summer-autumn forms were in reality *cateris paribus* just as easy to discover as the larger parasites. In short, in the writer's experience, microscopic diagnosis is generally as expeditious as it is beautiful, satisfactory, and complete. Staining was not used; the writer preferring for himself to study the living and moving haematocoon in its natural aspect. It may be added here that the writer, since making the observations above referred to, has demonstrated the parasite in three cases to several gentlemen interested in the subject. In two cases not previously examined the time between bringing the microscope to a focus and finding the first parasite was taken by means of a watch and was seen to be 100 seconds in one case and 105 seconds in the second; while in a third case microscopic diagnosis was made under two minutes. Any one who has been shown what to look for in the blood and how to look for it must feel a greater and greater confidence with every case in finding the parasite; and the writer is inclined strongly to endorse from his own experience the opinion of Dr MARSON and others that it is to be seen in the finger blood in the large majority of cases.

With respect to the causation of the disease, it may be stated that the regiment in which the cases occurred numbers some 800 persons, and is stationed in lines of huts about a mile from the marshy origin of a large tank. On first thoughts the marsh would be declared at once to be the origin of the malarial; but there are reasons to traverse this view. For instance, the disease showed a tendency to infect certain portions of the line more than others, though all parts are equally exposed to the marsh air. Thus out of 70 recruits who lived together in a stone-built house close to the front of the line, not one was attacked, though 100 of the remaining 730 men suffered. Again, in two houses at the extreme end of the camp, father, mother, and children, and all had the same parasite, namely, the summer-autumn variety. Such facts as these seem to

...fully to... on... hypothesis. The results of the writer's investigation of the habits of the insects, in the marsh, of the mosquito have already been given by Dr. MARSON before the July meeting of the British Medical Association, and he has had the good fortune of being able to observe that the evolution of the crescenter that only go on within the mosquito, but goes on to... than in finger blood. It should be added here that his observations on malarial fever in the marsh strongly suggest the truth of the same theory, and the opinion that the poison appears to have a much more localized and particular origin than would be possible on the supposition of a miasm generally diffused in the air.

IS THERE ANY TRUTH IN PHRENOLOGY?

By G. E. CLAYTON, M.D., F.R.C.S. & F.R.M.S.

On Special Plague Duty, Sindbad.

THE medical fraternity regard phrenology as a pseudo-science, yet, strange to say, though it has sadly degenerated since its pristine days, it rests on a scientific basis. Its originator, FRANCIS JOSEPH GALL, was an enlightened medic, an original thinker, a painstaking investigator, and, as he was in medical charge of a lunatic asylum, had every opportunity of studying the mental peculiarities of its inmates. Before his time there was no system in vogue for dissecting the brain, so though GALL's method is now longer adopted, he may be regarded as the pioneer of a systematic and practical method of dissection of the brain, and his method has paved the way for other methods of ability, which have certainly led to an intelligent study of the brain substance. All GALL's observations and experiences were compiled in a learned and most "interesting treatise entitled" *The functions of the brain*; and as the result of many years of patient, thoughtful, diligent study, he was led to map out the majority of the bumps with which phrenologists are so "au fait," and which have been caricatured as the science of craniology. Our modern methods of studying the cerebral organ, and the electrical researches of FENNER and others on the brains of monkeys, dogs, pigeons, etc., etc., have totally eclipsed GALL's method of observation it is true, and made the faculty think this savant was erroneous and unscientific in his deductions, and that these do not contain even a modicum of truth in them, but surely a man possessing GALL's mental calibre could not have erred from the truth as his opponents aver, and though his experiences do not tally with the experimental methods of modern neurologists, still, it might be yet proved, that the portions of the brain which do not respond to electrical stimuli, contain the bumps which GALL so laboriously sketched out. No one has yet disproved their existence. Quite recently Sir WILLIAM FENNER, in his address on "the Neuron and its relation to disease" (*vide British Medical Journal* 6th November 1897), has pointed out that the nerve substance, even in its simplest element the "axon cylinder" is a most complex structure, what then must the surface of the brain be, seeing it is studded with numerous sinuous convolutions and sulci, and possesses

grey substance which varies in thickness in different individuals? It is a well-known fact that the localisation of *F. Funaria* have been repeatedly confirmed by clinical cases, and that a knowledge of them has enabled the surgeon to ascertain with exactitude the bled clot or depressed fracture, and give relief in many cases of paralysis, but it has never yet been proved that GALL's method is incorrect, though we, with our conservative minds, and highly prejudiced feelings, have stigmatised it false, simply because charlatans have abused a science which was founded by one of its then ablest exponents, and by one who was certainly considered a leading neurologist in his day. Had GALL lived in the present age, he would have endeavoured to reconcile and harmonise his method with those now in vogue, and as he was a lover of his science, and did all he could for its advancement—his name being even handed down to posterity in the "columns of GALL" he would most undoubtedly have expunged all the dross, and retained only such matter as would have been of utility to a correct study of the brain. Professor ELLIOTSON, a contemporary of GALL, spoke in the highest praise of his "confrère," in his work on physiology, and most ably defended him against his many opponents. I myself believe there are yet undiscovered methods of investigating the "encephalon" that it only remains for future neurologists to bring these not only to light, but to also place phrenology on its scientific pedestal, and make its study tally with that of modern teaching.

THE INDIAN HOOKAH: A REAL SANITARY SMOKE.

By T. MONTON, M.D., L.R.C.P. & S. Edin., L.F.P. & S., Glas.

Muscoris.

THE question is often asked by patients, and as often answered evasively by consultants, which is the best smoke? To smokers in general it is of supreme importance to possess this knowledge. For a perfect smoke three elements are necessary: the absence of (a) heat, (b) products of combustion of tobacco, acrid matters and carbonaceous compounds, (c) nicotine. A variety of pipes have been invented to obviate the latter two, but heat has always defied pipes. Cigars, cigarettes, and pipes, so long as they are smoked in this world, will always produce it. In a hookah we have an ideal smoke, and though prejudice may retard its popular use for a time, it will hold its own against all competitors. The time is not far distant when all Europeans in India smoked their hookah without being ashamed of it. I remember some old military officers, only a few years back indulging in their cool hookah and inviting their friends, just as the better classes of

Hindus and Mohammedans do now, to sit down and have a pull at the hookah. An old officer, now over sixty-eight years, tells me that in the early days of Jom's Company every officer had his 'shisha' who looked after the hookah, and after dinner was ever at mass produced the graceful and sometimes be-jewelled hookah to adorn the table. It is fashionable at present to depreciate every thing Indian, and yet when we examine minutely the details of Indian custom and civilization, all are as a rule lost in admiration of the wonderful forethought, utilitarianism, and sanitary wisdom of those ancient people of a bygone age, who were the code manufacturers and law-givers of this land.

Revenous à nos moutons.—The Turkish *narghelia* is an elegant modification of the hookah, and I strongly recommend every smoker to invest in one, till such time as he can reconcile himself to a hookah with a long elastic, and coiled-up stem. When he reaches this stage, he will bless the hookah. He will enjoy the coolest and least harmful of smokes, and he will smoke less on the whole. The cigarette for various reasons is the most injurious and the most indulged in. An ordinary cigarette smoker burns up at least 20 a day, with the result that his throat is as raw as a beefsteak in the morning, and drier than a bone. If he is given to lifting his little finger, after every two or three cigarettes, there is a strong temptation to have a peg. He might drink water, but as modern literature warns him that there are thousands of bacteria in it, he generally goes in for a whisky and soda. I have come across numerous cases of pharyngitis, and a few of laryngitis in inveterate cigarette smokers. Besides, in some cigarettes there is a quantity of opium also. After a few puffs of these, the smoker either feels giddy, or sickish, and he attributes the effect to nicotine. It is nothing of the sort. It is pure and simple opium-smoking with its baneful results, emaciation, palpitation, dyspepsia, &c. The most scientific as well as the most ancient smoke is the hookah, and I strongly urge every one who has the courage to fight fashion and prejudice, to invest in one at once.

THE TREATMENT OF CHOREA.

DR. D. DE RENZI has confidence in only three remedies: 1. Absolute rest, avoiding any external excitation whatever, and placing the patient in a dark room. 2. The ascending electrical current along the spinal cord—the best results with a gentle current, progressively increased. 3. Atroscin in large doses, commencing with twenty drops of Fowler's solution each day for children, and doubling this amount for adults. When the chorea ceases medicine should be continued, for the disease returns readily. The nutrition of the patient must be maintained, and good food and gymnastics are essential.—*N. Y. Med. Rev.*

A CASE OF FIBRO-CYST OF THE UTERUS: ABDOMINAL DISTENSION; RECOVERY.*

By **MAJOR DILL BURNETT, M.B., F.R.C.S.,**
Surgeon of General Mission Hospital, Sialkot, and
SURGEON-CAPIAIN SMITH, I. M. S.

January.

The patient was a Mohammedan woman, 50 years old. She had three children, the youngest being 25 years of age. For eleven years she had noticed a small abdominal swelling. There was then menorrhagia. During the past year the swelling had rapidly increased, and during this period there was complete amenorrhoea. A very large abdominal swelling was found on examination, much larger than a full-term pregnancy. A diagnosis of ovarian or possibly uterine fibrocyst was made. The patient was in a fair state of health. She had been tapped two and a half months previously by a native practitioner. She was prepared for operation in the ordinary way and the usual antiseptic precautions were taken.

The operation on 12th December 1896 lasted 2½ hours. An incision was made from 1½ inch below the umbilicus to within 1½ inch of the pubes. On opening the peritoneum a small quantity of pale ascitic fluid escaped.

On passing the hand into the abdominal cavity, adhesions were found in both iliac fossae. The cyst was tapped with a trocar and cannula, and a large quantity of thick, bloodstained fluid escaped. The remaining contents being too thick to flow through the tube, and the tumour being too large and too adherent to get through the abdominal wound, the trocar puncture was clamped and the adhesions in the neighbourhood of the pelvis, which were very dense, were dealt with. The right broad ligament was included in a couple of silk ligatures and cut; on the left side the adhesions between the left ovary and the pelvic wall were treated in a similar way, the ovary being left attached to the cyst. The pedicle of the tumour was found to be the dilated and thickened cervix stert. This was transfixed and tied with stout whipcord in two segments, the ligatures interlocking. The opening into the tumour was next enlarged, and the hand being inserted, a quantity of material like degenerated placenta was removed. The body of the tumour was still so large that the wound had to be extended up to the umbilicus. Adhesions to the great omentum were separated, and the mass turned out and cut off just above the ligatures previously inserted into the pedicle. The mucous membrane of the stump (cervix) was dissected out and by a few silk ligatures was drawn together like a fish mouth, so as to cover it with peritoneum. The peritoneal cavity was washed out by pouring in gallons of hot boiled water till it came out clear. The abdominal wound was washed with antiseptic gut stitches through all the layers of the abdominal wall, and a drainage tube was inserted. Both uterine tubes were removed, the left one being attached to the cyst. It was normal, the right was enlarged and cystic. The cyst was an enormous one, with a wall varying from 1 inch to 1½ inch in thickness.

The patient recovered well, leaving the hospital for three days. She or her mother was in a moribund condition, but rallied after hypodermic injections of strychnine, strychnine, and morphia.

From the fourth day onwards an uneventful recovery; her temperature never went higher than 101°F. The tube was removed at the end of three days, without disturbing the rest of the wound. The wound was dressed on the ninth day, and the cicatrizing completed. It had healed by first intention, except for a small dry slough where the tube had been. This was quite healed in a week's time. The patient was discharged well at the end of a month, and has continued so since.

Our thanks are due to Dr. Tasson, who gave chloroform for us, and to Miss MacKenzie, M.B., who assisted us at the operation.

Not many successful cases of abdominal hysterectomy have been recorded in the Punjab. The difficulties of the case, the size of the cyst, the adhesions, and the recovery of the patient seem to make the case worthy of being recorded.

CASE OF SPONTANEOUS AMPUTATION OF BOTH LOWER EXTREMITIES IN A NEWBORN INFANT.*

By **SURGEON-CAPIAIN, C. DURE, I. M. S., M.B., F.R.C.S.**

Junior Civil Surgeon, Rangoon.

In July 1896, a healthy-looking young Burmese woman, aged about 22 years, brought her male child, aged 2 months, to the General Hospital. She said that the labor was natural, and the child healthy and well-formed. The day after birth she noticed some black and blistered blotches on the backs and fronts of both thighs, and the lower extremities were very cold. The lower extremities swelled and became black, and "the smell was like that of a dead body some days old." The lower extremities gradually separated, and there was no hemorrhage. She had three children before, and all were healthy.

The child was healthy and well nourished, but both lower extremities were wanting. On the left side there was an oblique, firm, depressed scar over the face of the stump. On the right was a similar scar, but projecting from its centre and surrounded by a small area of ulceration was the black shaft of the femur, which was easily separated by twisting. The heart sounds were normal, and all organs were apparently healthy.

I am not able to discover any reports of similar cases. The case is probably one of the moist gangrene resulting from sudden obstruction of the lower end of the inferior vena cava, occurring either during labor or soon after delivery; but further explanation seems difficult. Unfortunately the mother was not asked whether the child moved its legs. The natural separation of two fully developed lower limbs without a fatal result is also worthy of note.

SUCCESSFUL LAPAROTOMY WITH REMOVAL OF BOTH FALLOPIAN TUBES FOR ACUTE SUPPURATIVE PERITONITIS, SUPERVENING UPON DOUBLE PYO-SALPINX.

By JAMES R. WALLACE, M.D., F.R.C.S.
*Fellow of the Obstetrical Society of London,
Formerly Resident Surgeon in the Eden Hospital
for Women and Children, Calcutta.*

Mrs. B——, a Scotch lady, 28 years of age, of very delicate physique, for some years, a resident of Calcutta six years married, gave birth to her first and only child, 10 months after marriage. No further issue. Has suffered with ovarian pain since her child's birth in June 1888. Came under my care about three years ago for menstrual trouble. Was completely relieved and seemed to regain her health in every way. Being one of my regular annual patients, I frequently saw her, and by means of sedatives timely given, her sufferings were minimised, though every now and again they threatened badly. During my absence in England, she got a severe attack of pelvic inflammation and was attended in August last by Surgeon-Lieutenant-Colonel J. LEWIS, under whose care she obtained very satisfactory relief. Early in October, she was laid up again with pelvic cellulitis, supervening upon a severe chill, due to bathing in a very windy bathroom. Her temperature rose to 105 and kept ranging between 102 and 104 for days. There was intense nausea and vomiting and great pelvic pain and tenderness, more marked in the left iliac region. There was the most troublesome restlessness and insomnia, due to pain, which narcotics and hypnotics could not relieve. Fomentations, local sedatives and counter-irritants all failed to afford anything more than very transient comfort in her great suffering. Examined vaginally and bimanually, the uterus was found immovably fixed, in a dense, hard mass of infiltration, filling the left, and extending partially into the right cul-de-sac. This swelling almost reached to the umbilicus above and pressed firmly on the sacral hollow. It was devoid of resiliency or any sign of fluid formation. This state of things continued till the 8th November, when on examination I detected distinct fluctuation in the left cul-de-sac. The patient had now become very low, and as the exhaustion coupled with the high temperature present, pointed to considerable risk, I advised a consultation with some other physician. I therefore asked Surgeon-Lieutenant-Colonel A. LEAHY to see the case with me. He confirmed my opinion as to the fluid formation in the left iliac region, and agreed with me in the view that immediate aspiration should be resorted to. I accordingly called in Dr. J. G. ANDERSON, who chloroformed the patient, and I aspirated the left cul-de-sac, drawing off nearly five ounces of thick, gray-colored pus. This was followed by immediate relief and comfort, and sound sleep, together with a fall of temperature to normal. For three days the patient seemed doing most satisfactorily, but on the fourth day after the operation, pain and tenderness returned, together with fever which rose again to 104, attended with the same restlessness and insomnia.

On the 14th October the patient was very much worse; the abdomen was greatly distended and tympanitic, and acutely tender to the touch; the pulse was small and

thready and infrequent; the body was covered in cold perspiration; and collapse seemed imminent. Vaginal examination proved a re-accumulation of pus in the left side of the pelvis, while in the right cul-de-sac there was a similar fluctuant tumefaction. I called in Dr. LEAHY, as I felt convinced that general pelvic suppuration with peritonitis of a like character had set in, and the saving of life could only be effected by abdominal section and rapid washing out of the peritoneal cavity. Dr. LEAHY concurred in this opinion, and I resolved to let the patient have the best and only chance of recovery. Her critical condition was explained to her and her husband, and the risks of the operation were also clearly set forth to them. They both readily decided for the operation. The room was an upper flat, airy apartment, surrounded on every side by other houses, and in the most densely populated portion of the English quarter of the city. The room having been thoroughly swept, the walls well dusted, all hangings removed, and the floor washed with a strong solution of carbolic acid, nothing but the operating table, the nurse's bed, a couple of chairs and side tables were placed in it, every other item of furniture being turned out. As helps at the operation I had Dr. AYATULLA, M.B. Edin., Mrs. E. W. MADON, L.M.S., and Nurse ROBSON.

As it was decided to operate at 2 P.M., no food was given to the patient from 10 A.M. At noon anæmia was administered and the patient's bowels were relieved, her bladder was also emptied and the hair shaved from the pubis, while the abdomen and thighs and back were thoroughly washed, and a sterilised towel soaked in hot carbolic acid solution was laid over the abdomen and the vulva, and tucked under the nates. The preparations for the operation were simple and were as follows:—About 40 gallons of pure boiled water, cooled down to 100°F; a dozen new hand towels, two new flannel binders, 4 yards of gauze, some cotton wool, a dozen sponges, a two-quart irrigator fitted with a new rubber tube, stop-cock and pipe; a bucket, a glass tray for instruments, and two pus basins. The instruments for use were a scalpel, a dissecting forceps; a pair of dressing scissors, a director, six Spencer Wells' forceps, two metal retractors, six curved surgical needles and a needle-holder, besides silk, silver and horse hair sutures. *Everything* used in the operation was sterilised, i.e., put into boiling water for twenty minutes, except rubber tubes, which were irrigated and carbolised.

At 2 P.M. the patient was placed under chloroform by Dr. AYATULLA, the abdomen and other parts were carefully bathed and scrubbed clean, and the two assistants (Mrs. Dr. MADON and Nurse ROBSON) and myself, having first of all undergone the most careful cleansing of our hands and nails and arms, (each one's nails were cut short) by means of repeated washing with soap and boiled water, and scrubbing with nail brushes, the abdomen in the median line, was laid open carefully down to the peritoneum, by an incision 4 inches long. All bleeding points were secured and the peritoneum nicked up and slit over a director. The peritoneum was found thickened and inflamed and covered with tarry deposits of fibrin which had caused firm adhesions between this membrane and the intestines. By gentle manipulations these were freed, and then the true state of things in the pelvis was revealed. The pelvic cavity was filled with an indescribable mass of

The pelvic organs were found to be completely absorbed by inflammation and suppurative changes. Most carefully and carefully, however, the uterus was lifted and then the ovaries were touched and it was seen that the tubes were enormously distended with pus. They were both freely incised and about eight ounces of pus came away. This was removed from the pelvic cavity by means of soaking with sponges. It was now found that the membrane of the tubes looked very sloughy, almost gangrenous, so I snipped off all the unhealthy looking shreds and finding the ovaries healthy, I left them untouched. I now allowed a stream of sterilised water to flow into the abdomen and the roughly wash out its entire cavity. Having assured myself that there were no bleeding points (the few that showed themselves were stopped easily by a few moment's pressure with Wells' forceps), and that the pelvis was thoroughly clean, I placed a large rubber drainage tube into the pelvic cavity and fixed its outer end to the lower angle of the abdominal wound. This was removed after 48 hours. I now stitched the edges of the incision together, using three consecutive layers of stitches, the first of silk for the peritoneum, the next of silk for the abdominal muscles, and the third of silver wire for the abdominal wall (skin and fat). Superficial horsehair stitches were used to accurately coapt the edges of the cut skin. The dressings consisted of sterilised gauze and sterilised cotton kept *in situ* by a sterilised towel used as a bander. This dressing was not changed for two days. The patient bore chloroform well and also the early part of the operation, but by the time she was dressed, the pulse had run down alarmingly and she was in a state of collapse. An enema of brandy and egg yolk and milk (the yolk of one egg, a dessert spoonful of brandy and two ounces of milk) was given per rectum and repeated every two hours. Hot bottles were placed around the trunk and extremities. She was allowed to suck ice, but nothing else was given her by the mouth for 48 hours. After the first rectal injection the patient rallied and continued to improve. Beyond a little burning pain in the wound, the operation was followed by a complete subsidence of the fatally threatening peritonitis and absolute relief of all pain, a complete lowering of febrile temperature and the most refreshing sleep. Nothing could have been more gratifying than her condition for the first 48 hours after the laparotomy. Within 8 hours of the operation, the patient voided urine, and within 20 hours the bowels moved naturally. On the second day after the operation, after the removal of the dressings, the patient began to suffer with a teasing sense of twitchings in the wound, but this was due to flatulence, as it was relieved by a dose of oil of turpentine. This was accompanied by some degree of restlessness and sleeplessness, which were combated by Battley's sedative.

The diet after the first 48 hours (when the rectal feeding ceased) was soup, sago, milk, water and grapes, and this was continued till the 8th day after the operation when light solid food was allowed. The outer stitches were removed on the 8th day, and the wound was found healed by first intention, save in a spot over one of the deeper sutures. From this place a little pus oozed for a few days, and then I closed the gap with a horsehair stitch and it healed at once. There is nothing further of special interest to note, save that the subsequent convalescence of the patient was unmarked by a single bad symptom. It is of importance to remark, from a clinical, as well as a physiological and anatomical point of view, that the patient had a free and painless menstruation 34 days after the operation. It may be interesting to mention that on the 14th day after the operation, she was well enough to sit up, that she left her bed on the 20th day and was going about in her carriage on the 30th day, though she underwent so severe a surgical operation for a serious and critical malady which threatened to destroy her life.

This case is further worthy of record among the few successful ones of its kind that have been performed in India.

Indian Medical Record.

1st January 1904.

AGUE OR INTERMITTENT FEVER. ARE THE PHYSIOLOGISTS OR THE PLASMODIISTS RIGHT?

We have received a very interesting and suggestive pamphlet with the above title, by Brigade-Surgeon Lieutenant-Colonel M. D. O'CONNELL, M.B.,^{*} Officiating P. M. O., Rawal Pindi District, in which the author advances the theory that the phenomenon observed in ague are due to an increase of water in the blood, and that this change is entirely dependent upon climatic causes.— "Meteorological environment."

He casts doubts upon the parasitic nature of LAYHAN's bodies, and we must confess that these bodies, their various forms, and the changes they undergo, are somewhat disappointing, and he further shows that, according to the opinions of physiologists, changes in the blood can be brought about by other means (excess of water and heat) which cause the corpuscles to assume appearances similar to the appearances ascribed to LAYHAN's parasite by all observers.

He compares the opinions of physiologists and "plasmodiists" as follows:—

PHYSIOLOGISTS TELL US

1. If water be added to normal blood, the red corpuscles lose their discoid form, become spherical, swollen, and *dropical*, the hemoglobin is washed out of them, and ultimately they disintegrate and disappear.

2. If blood be *heated*, vacuoles are produced in the red corpuscles which appear as little, clear, colorless shining spots that assume spherical, annular or other forms. They change their form. They increase in size till they occupy half, two-thirds or the whole of a corpuscle. They exhibit amoeboid movements form contractions in the surrounding hemoglobin, and they throw out little fine-headed prolongations which pass to and fro. There may be one or more vacuoles in each corpuscle.

3. If water be added to normal blood and the specimen heated a few degrees above normal, the white blood corpuscles which may or may not contain pigment exhibit active amoeboid movements, and brownian movements of the contained pigment.

4. The result of increase of water in the blood and exposure to increase of temperature, is destruction of red corpuscles, and production of pigment free and enclosed in fragmental and various shaped bodies.

PLASMODIISTS TELL US

1. The red corpuscles attacked by the malarial parasite are usually the larger ones. They lose their discoid shape and become spherical, swollen and *dropical*; they lose their color and ultimately disappear.

2. Malarial parasites appear in the first instance on or in the red corpuscles as little clear colorless shining spots of various forms, spherical, annular or other. They change their form. They increase in size until they occupy most or the whole of the corpuscle. They exhibit amoeboid movement, and throw out flagella. There may be one or more parasites in each corpuscle.

3. The larger spherical pigmented parasites exhibit active amoeboid movement, and their contained pigment exhibits active wringing movement.

4. The result of invasion of the red corpuscles by the parasites is wholesale destruction of the corpuscles and increase of pigment in the blood, free and enclosed in spheres, crescents, etc.

^{*} Note.—The pamphlet is published by Messrs. Thacker, Spink & Co., Calcutta.

These experiments are certainly admirably fitted to attract the student's attention.

To account for the mechanism, he refers to Professor HENRIKSEN's theory on blood decomposition (*Lancet*, 26th November 1897). According to him the causes of hæmoglobin, or blood destruction, are of two kinds: direct and indirect; the first consists of agents injected with the blood, such as arsenic; the second acts from within through the spleen cells.

LAVERAN describes the appearance in the blood, during the progress of hæmoglobinæ, produced by the injection of water; of the following:—

1st *Coloured spherules*.—Albuminous and highly refractive of varying size.

2nd *Coloured spherules*.—A red corpuscle becomes constricted at some portion dividing into two parts connected by a colorless portion. These are best studied by warming blood to 45°C (a temperature not much above portal blood in a paroxysm of ague) when the corpuscle breaks up into a number of colored spherules. This description of the disintegration of a blood corpuscle produced by a temperature of 45°C, plus addition of water, reminds one of the description of sporulation of parasites, said by plasmodists to occur during each paroxysm of ague.

That there is an actual increase of water in the blood in all cases of ague, he brings forward no new experiments or researches to prove, but relies upon LAVERAN's authority.

"LAVERAN," he says, quoting from *Fagge*, Vol. I, p. 48, "seems to have established this, for he declares that the wasting of the body in ague, is sometimes concealed by the excessive amount of water contained in the blood and tissues. From this cause the weight of the body may be increased as much as 10 lbs, although there may be only slight oedema of the ankles to indicate an excess of water in the blood and tissues."

But the word ague does not occur in the original; LAVERAN's remark refers to fevers in general, and it should follow according to Dr. O'CONNELL's theory, that as there is an excess of water in the blood in all fevers, there should also be the bodies described by LAVERAN, provided the temperature reaches a certain point; and this seems to us a weak point in Dr. O'CONNELL's contention.

As to the manner in which the "meteorological environment" brings about an increase of temperature and of the water in the blood, he refers to experiments by LAFF and HEILGENTHAL on the effects on the body of increased temperature and increased humidity of the atmosphere.

"By exposure in a Turkish bath, or hot dry air-bath to a temperature of 140°F for 50 minutes, the temperature of the body was only raised to 104.6°F. On the other hand, exposure in a Russian or hot vapour bath of only 118°F for only 30 minutes, raised the body temperature to 104.6°F."

"In the hot, moist atmosphere of the Russian bath, evaporation from the skin and lungs is impeded, if not arrested. The natural cooling function of the skin being thus arrested, the body-temperature must, of course, rise, as it does in the vapour bath."

But besides impeding evaporation from the skin and lungs, exposure in the hot vapour bath also produces retention of water from the kidneys. It must therefore produce accumulation of water in the blood. The most obvious effects of exposure in a Russian or hot vapour bath are these.

1st—Increase of water in the blood.

2nd—Increase of temperature of the body.

Bearing in mind the above results of exposure in the hot, moist, stagnant atmosphere of a Russian vapour bath, it is evident how exposure to the hot, moist, stagnant atmosphere of malarial climates will as certainly, if not so rapidly, produce the same effects.

And this brings us to the starting point of his argument that the climatic conditions under which ague is most prevalent, are the conditions most resembling a Russian vapour bath.

He says:—"The meteorological environment under which ague becomes most prevalent is a hot, moist, stagnant atmosphere."

The example he takes to illustrate this is Singapore. In this statement and in his illustration we do not think he is very fortunate. Singapore, far from being a malarious place, is rather famous for the opposite character.

In the table given in the pamphlet Dr. O'CONNELL gives the rates of admissions for Singapore as 409 per 1,000. We do not know where this figure is taken from, or what it refers to, but even if it were correct, it would not at all compare with Mian Meer, the figure for which in 1895 was 1,413 admissions per 1,000.

According to the Army Medical Department Report for 1895, the admission rate amongst European troops in the Straits Settlements, of which Singapore is the healthiest part, was only 46.8 per 1,000, and this was higher than the preceding year—a fact which the P. M. O. accounts for by saying—"The majority of cases occurred in the Northumberland Fusiliers, which had recently arrived from India."

The average admissions per 1,000 from 1886 to 1894 was 114.4.

Singapore is therefore a far less malarious place than Mian Meer, and so also is the whole of the Madras Presidency, but no one will have a doubt where the conditions of excessive heat and moisture are most constant.

We do not consider that this point invalidates Dr. O'CONNELL's main thesis, though it is certainly deserving of his attention.

We need not enlarge upon the ingenious manner in which Dr. O'CONNELL brings his theory to explain not only the different forms of ague, as tertian, quartan and quotidian, but also the causes of susceptibility and immunity, and we can only hope his views will receive more attention than is usually accorded now-a-days to anything that does not emanate from the bacteriological laboratory.

MEDICAL EDUCATION IN GREAT BRITAIN WITH HINTS TO INDIAN STUDENTS.

As the question of medical education in Great Britain is an important one, having a fascinating interest to many ambitious students and practitioners in India, who cherish the aspirations and the hope that they will some day acquire diplomas from the Home-land, on which based on the latest educational measures of the British Medical

... we are now in a position to study of our system. Before entering upon the study of medicine, the would-be physician should know that five years of most arduous work is required of him, and that the days of unthinking indifference are over, the more so as the standard of admission to the portals of the profession has been considerably raised during the past few years. After deciding as to the medical school he is to study at, the first thing to do is to pass the preliminary examination, as no school course counts as part of the "annus medicus" until this has been accomplished. The possession of a degree in arts from any British or Colonial University or some of the higher British schools having certificates, exempt from this examination. It is essential that no candidate for medical study should attempt to leave India unarmed with this passport to admission to the British medical course, as failure to pass the preliminary examination in Britain would entail useless and expensive labor at mathematics and English literature and foreign languages. Allowing that an Indian candidate has completed his full five years' course of the medical curriculum, he is eligible for examination by any of the British Corporations. In the case of British or Irish Universities, a brief residence of from six to twelve months is demanded before a degree can be competed for. Supposing that a candidate purposes putting in a full course at a British school, then comes the question as to the choice of the school. There is scarcely any room for choice with regard to the London medical schools. They are all well equipped and well officered, but St. Bartholomew's and Guy's are reckoned as being somewhat better than the others. In Scotland we have Edinburgh, Aberdeen, Glasgow, St. Andrews and Dundee. Edinburgh stands to the fore "in the land o' Cakes and brither Scots." The Royal Infirmary here contains about 800 beds, and is at present being extended. It is in close proximity to the University, the classes of which are so arranged as to suit the clinical work in the hospital. The opportunities for both observation and practical work in the Royal Infirmary are many, *eg*, the student makes the clinical report of the case allotted to him and reports daily to the Resident in charge, any serious change of condition. Again he anaesthetises his own patient if operation be necessary, and under chloroform he is permitted to perform the gynecological examination. Of the professors of the Edinburgh University, we need not write, as their fame is world wide, the mere mention of their names will suffice.

Professor Simpson Midwifery.
" Fraser Materia Medica.
" Sir T. Grainger Stewart Medicine.
" Chiens, Surgery.
" Annandale Clinical Surgery.
" Sir Douglas McLachlan, Medical Jurisprudence	
" Rutherford, Physiology.
" Greenfield, Pathology.

Again, the city itself offers many attractions. Besides being the capital, it is one of the safest and healthiest of our Scottish cities. One of the great advantages the Edinburgh medical student has is the extra-mural teaching, which attendance kindly encourages; so that if the style of lecturing of any of the professors is objectionable to him,

he can take out the class of either of the extra-mural schools. Of course this can only be done to a limited extent; three subjects in all being the number allowed. So far as we know, the extra-mural teaching is only carried on at Edinburgh. As to the cost of a medical education, this varies greatly with the student himself. The class fees, of course, are fixed—£ 4-4 for each theoretical and £ 2-3 for each practical class. This would indicate about £ 120 during the 5 years for class fees alone. To this must be added the cost of the four professional examinations,—a sum of about £ 22—and again books and instruments have to be borne in mind, which requires a sum of at least £ 40. So that, roughly speaking, a sum of £ 200 is almost necessary for the educational part.

The cost of living is entirely in the hands of the student. Rooms can be had from 6s. a week upwards to almost any price. Approximately the weekly bill in Edinburgh may vary from 13 to 21s.

Now concerning the subject of text-books in general use.

Anatomy.—On systematic anatomy the standard text-books are Quain and Gray. Both are well up to date; the former is the more comprehensive of the two. Smaller works, but which suit students equally well, are Turner, Owen, MacAlister, Mackay and Cleland, all of which treat of systematic anatomy.

The favorite text-books among dissectors are Ellis, Heath, and Cunningham. For the study of the dry bones—perhaps Holden is as good as any.

Surgical Anatomy.—That of Fred Treves is the most popular.

Physiology.—Foster, 4 parts, is the best English text-book of the subject. *Landois and Sterling* is more for reference than for student work. *Kirke*.—Compact summary of the whole subject of physiology.

Histology and Embryology.—So far as the student is concerned, these subjects are treated fully in his physiological and anatomical text-books.

Chemistry.—Roscoe and Thorpe are very good on Inorganic and Bensen or Key holds for Organic.

Physics.—Balfour Stewart or Alfred Daniel, both of which are excellent companions to lecture notes.

Biology.—Prantl and Vio on Botany; Arthur Thomson on Natural History; Ewart's dissection of the frog, are all excellent text-books.

Materia Medica and Therapeutics.—Lauder Branton, (22/6), more adapted for senior students. Garrod (12/6); Hale White (7/6); Mitchell Bruce, excellent for students.

Medicine.—Fagge (40/), for depth and thoroughness it is unequalled. *Quain's Dictionary* also an admirable work.

Smaller works but more suitable for student purposes are those of Osler (24/); Bristowe (31/); Taylor (15/); Roberts and Burney Yeo.

Clinical Medicine.—Judson Berry (21/); Finlayson (8/6); Gibson and Russell (10/6); Jackson (25/), all excellent and reliable works.

Surgery.—The standard English text-books on the science and art of surgery are those of Erichsen and Treves. Smaller works are those of Walsham, Heath, Mansell Pleydell and Caird and Guthrie; the latter being an excellent book for emergency cases.

Operative Surgery.—Telford, Bell and Jacobson are excellent guides.

Midwifery.—W. B. Playfair is, we think, the most widely read on this subject; other reliable works are those of Galabbe, Luck and Harman.

Handbook issues a small compend, handy for pocket use.

Gynecology.—Hart and Barbour, a favorite work among students, thorough and comprehensive in all detail.

Lawson Tait and Bland Sutton on diseases of ovaries.

Diseases of Children.—Ashby and Wright (25/); deals with both surgical and medical diseases, contains all one requires to know. Smaller works are those of Carmichael Owen, and best of all Smith.

Pathology.—The principal works on the subject are Coates, Payne, Hamilton, Ziegler and Sims Woodhead.

Diseases of Eye.—Swanzy, George Berry, both suitable for students.

Forensic Medicine.—Taylor (14/); Guy (16/); authoritative books.

Public Health.—All that is necessary for this subject, so far as medicine is concerned, is a course of 80 lectures, and the general text-book used by students is that of Lewis Parkes. If a degree in Public Health be desired, then special courses including analysis of food, air and water must be taken out.

Bacteriology.—The elements are given in the ordinary pathology class, but special courses can be had in this subject, also the principal works are Sims Woodhead, Schenk, Salomonsen, Vaughan, and Kuntback.

Psychology.—The more important works are Clouston, Savage Sully, a perusal of which will repay the student. If one intends taking a degree in mental science, then a special course is necessary.

We think we have mentioned the outstanding features of our profession. The study, though hard, will more than repay one, and the knowledge he obtains of the working and mechanism of the human frame and of his ability thereby to treat and cure the ailments of his suffering fellow-men, is well worth all the time and money he can devote to its acquirement.

—:o.—

THE FOURTH ANNUAL GENERAL MEETING OF THE INDIAN MEDICAL ASSOCIATION.

IN accordance with the notification duly given in the *Indian Medical Record* of the 16th December, the Fourth Annual General Meeting of the Indian Medical Association was held at the residence of Dr. WALLACE, the Secretary, at 50, Park Street, Calcutta, on Monday, the 27th December at 6 P.M. There was a fairly large attendance of members. Telegrams, congratulating the Association and wishing the Annual Meeting great success, were received from H. H. Sir BHAGVAR SINGH, G.C.I.E., M.D., F.R.C.P., Thakore Sahib of Gondal, Vice-President of the Association, from Dr. A. MITRA, of Kashmir, Representative in Council for the Independent States of India, from Professor CALEN, Representative in Council for the Punjab, from Dr. JOHN MORTON, Representative in Council for the N.-W. P. and Oudh, and from Dr. C. NAYLOR, Representative in Council for Madras; other telegrams came in later. The President, Dr. LAL MADHAR MUKHERJI, Rai Bahadur, F.R.C.P., being unavoidably detained, Dr. E. W. CHAMBERS, Vice-President, was voted to the chair, and with a few words of greeting to his audience, opened the proceedings of the evening by calling upon the Secretary to read the Report of the year.

THIRD ANNUAL REPORT OF THE INDIAN MEDICAL ASSOCIATION.

THE Secretary has the honor to submit the following Report of the affairs of the Indian Medical Association for the year 1897:—

1. Membership—

The members may be classified as follows, showing the growth of our body for each year:—

	For 1894.	1895.	1896	1897.
Army Surgeons	...	2	44	51 55
Independent Physicians	...	71	105	123 157
Civil Surgeons	...	72	94	102 111
Civil Assistant Surgeons	...	79	95	122 135
Military Assistant Surgeons	...	173	194	260 318
Hospital Assistants	...	49	65	87 132
Total	...	452.	617.	745. 908

There have been no withdrawals from our Society, but two deaths have occurred among the members of the Association during the year.

2. The Council and its Meetings.

The Council has held four Meetings during 1897, and all were well attended.

One member of Council (Dr. MONEY LALL DUTT), died during the year, and his place has been filled by the election of Dr. RAKHAL DAS GHOSH.

Three additions have been made to the Council under the new regulation concerning the direct representation of the local services. Dr. HARI DATT PANT, being appointed to represent the Civil Assistant Surgeons' Service, Surgeon-Major JAMES FORSYTH to represent the Military Assistant Surgeons' Service, and Mr. M. I. PHILIP, S.H.A., to represent the Hospital Assistants' Service. Dr. ARTHUR FOY, Member of Council for Bombay, having retired from the country owing to ill-health, and Dr. MCCABE DALLAN, Member of Council for Assam, having removed to Bombay, he was appointed Member of Council for Bombay, while Dr. WILLIAM BROWN was elected to fill the post of Member of Council for Assam. Dr. N. N. PARAKH of Rangoon, was elected to fill the place of the late Surgeon-Major GODDER as Member of Council for Burmah.

The Secretary takes this opportunity of referring to the great loss which the Council has suffered by the lamented death of Dr. Dutt. He further acknowledges with much pleasure and thankfulness, the ready and very cordial assistance he has received from our worthy President and every Member of Council in all his labors. Our colleagues have given up their scanty leisure cheerfully at the call of duty, and their work has been of the greatest value in determining upon the questions that have arisen for deliberation. The Secretary was absent in England during six months of the current year, and his duties were ably carried on by Surgeon-Major HODGKINS.

3. The work of the Association:—

(a) The chief aim of our Society has been directed towards uniting and cementing the bonds of union among the scattered members of our profession throughout this land. It has been felt, up to the present time, that the *raison d'être* of the Association, the necessity of its existence, is foreshadowed in the great task of up-building, developing and advancing all that pertains to the interests and prospects of locally educated

and other domestic independent practitioners, both Indian and European, of every grade, whether in the service of Government or out of it. It has not been called upon to do anything that concerns the higher medical services of this country, and hitherto its field of labor has been entirely confined to safe-guarding the interests of independent medical practitioners and the local medical services. The Association has not pretended to do any scientific work, though, when well established with funds, it will endeavor to aid the advance of medical science in some tangible form; this being one of its objects. At present its attention is absorbed with such questions as affect the social and material advantage of its members, and to this end the society has directed its best efforts. That the labors of the Association have been appreciated and approved of by its *clients*, is apparent from the steady growth of its membership, and by the fact that no form of dissension has arisen from its wise and carefully conducted policy, such as would be indicated by the withdrawal of members.

(b) *The Formation of Branches of the Association.*—

No new branches have been formed during the year. The only one that exists is the Straits Settlements Branch, and this body is doing excellent work.

(c) *Medical Reform in India.*

Owing to the disparaging delay in responding to the appeals to Government by this Association, the Council deemed it imperative to approach the various Provincial Governments with a renewed attempt to obtain redress for the grievances of Civil and Military Assistant Surgeons, and Civil and Military Hospital Assistants. It is hoped that the recent action of the Council in addressing the Imperial and Provincial Governments on this subject, will result in early and favorable action being taken by the State. The Council found it necessary to approach the N.-W. P. and Oudh Government in connection with the important question of the interference with the rights and privileges of the independent medical practitioners in Mussoorie, by the Civil Surgeon of that Station. A strong case was made out by the Government itself, for insistence upon State-paid Surgeons being confined wholly to their legitimate official duties, and it is anticipated that the Government will see its way to prohibiting the highly paid Civil Surgeon of Mussoorie, from competing in private practice with the independent surgeons in that station.

(d) *Representations to Government by the Council.*—

The Council has approached the Supreme and Provincial Governments on the following matters during the current year:—

1. Calcutta Sanitation and Plague Segregation.
2. The granting of Fellowships in the Calcutta University to our President and Vice-Presidents.
3. The grievances and disabilities of the local Medical Services.
4. The question of Government Surgeons and Private Practice.
5. The appointment of a representative of the Association on the Bengal Plague Commission.

(e) *Medical Registration for India.*—

In view of the sanction of the Government with regard to the subject of a Medical Registration Act in India, the

Council has approached the General Medical Council of Great Britain, to lend its powerful aid to the inauguration of a system of compulsory registration on all practitioners holding British qualifications and Indian University degrees. It is felt that the acceptance of this measure will prove to be the first step towards a perfect system of general medical registration in this country. It will serve also to emphasize the anomalies of medical education in India, and will undoubtedly in the near future, bring about not only a better and more perfectly equated standard of education and examination in all the State Medical Schools, which will tend to the betterment of the social and material status of the local profession, but it will put an end to fraudulent practices by men who dare to boast of spurious medical qualifications, and even go the length of affixing false titles to their names, when they have none at all.

(f) *The Indian Medical Association Provident Fund.*—

This important scheme though growing slowly, has had a somewhat discouraging growth during the current year. It was promulgated in February, and up to the present time, only 250 members have enrolled their names on its list. The amalgamation of the Medical Warrant Officers Provident Fund and our own Fund, has been accomplished by popular vote, and it is hoped that ere long, the full complement of membership will be attained and our own Fund satisfactorily launched on a firm basis.

(g) *Change of Rule.*—

It has been found difficult at times, during the past three years, to carry on the work of the Council, owing to inability to form a quorum under Rule 18, by which the quorum is fixed at six. It is felt that the number should be changed to four, and therefore this matter is now placed before the Annual General Meeting for alteration.

(h) *Election of Officers and Council.*—

As under Rule 11, the President, Vice-Presidents, Treasurer and Secretary, having now filled their offices for three years, are compelled to retire, and as all the Members of Council, are by the same rule, compelled to do the same, they shall at the present Annual Meeting retire and seek re-election.

(i) *Honors to our Officers.*—

It is a very pleasing duty to refer briefly to well merited honors that have fallen on the leaders of our Association. Our excellent and revered President, Dr. LAL MADHAN MOOKERJI, has been greatly honored by His Majesty, the King of Nepal, who received him in open durbar, as a mark of respect and esteem for his valuable work as an Ophthalmic Surgeon. In successfully operating for cataract, on a patient in Nepal, aged 106 years' Dr. MUKERJI added another score to his already renowned skill as an operator. His Excellency the Commander-in-Chief of Nepal also made very valuable gifts to Dr. MUKERJI for his able and successful professional attendance on himself. Dr. MUKERJI was the recipient of the very handsome presents and also of a very elegant Gold Medal on this occasion, and the Maharaj, the Prime Minister who made the presentation expressed the high appreciation of our President's skill and reputation as an Ophthalmic Surgeon. I have also to refer to our worthy and esteemed Vice-President, Sir BHAGVAT RAMJI, M.D., F.R.C.P., &c., who received during his recent visit to London, where he was specially invited

INDIAN MEDICAL ASSOCIATION BALANCE SHEET.

H. C. HODGKINS,
Hon'y. Treasurer.

CALCUTTA,
27th December 1897.

In the absence of Dr. MUKERJEE, Dr. CHAMBERS called upon Dr. R. D. GHOSH to read

THE PRESIDENT'S SPEECH.

LADIES and GENTLEMEN, I am sure, we are all gratified with our Secretary's excellent Report for 1897. It speaks of energy and zeal and faithfulness, and of success all along the line. It growth is a sign of progress, then the Indian Medical Association can prove, by its increasing membership, to be progressive both in popularity and usefulness and in public influence. Unquestionably our Society has won the confidence of the local profession in all its grades, and a review of its work, as revealed in the Report just read to us, exhibits a good measure of concern in the welfare of the local services and of the local profession, as

well as a keen perception of the public needs in medical matters, that may well call forth the assistance of all right minded men and women in India. Thanks to our Council, the year that is now closing, saw but of a handful of men and labor on behalf of the professional brethren. After three years of hard work, we can honestly claim, that our Council and our Association have abundantly justified their existence, and that we have nothing to blame ourselves for in all that concerns our responsibilities as the representatives of the local medical profession.

We all read the *Indian Medical Record*, and therefore we all know the sphere and scope of the labors of our Council.

I wish now however, to urge once again the claims which our Council holds upon the grateful appreciation of the local profession, and to emphasize the duty that ought to be clear to every medical man and woman in India, outside the higher or imported medical services, to join our Association. This is a step which our brethren should no longer hesitate to take. We annually publish the *State of our membership*, we report every item of business we transact, so that our doings and our position are all clear and above board. If our efforts and endeavors on behalf of the local medical services, and the profession generally, have not been happily attended with well merited success, blame cannot be ascribed to us, but to the apparent supineness and indifference of the medical authorities in India. I have no hesitation in saying that the neglect meted out by the State to the grievances and disabilities of the local medical profession, is a very serious blot upon the medical administration of this country. Bad as things may be with the A. M. S. in England, nothing can compare with the lamentable condition of the so-called *Subordinate* or local medical services. The state of dissatisfaction and excitement throughout these services, is akin to a hopeless want of confidence in the Government, in regard to its policy towards the local services, and I feel it my solemn duty to inform the authorities that this strain is likely to be followed by wholesale retirement, and resignations, a calamity that would be most disastrous both to the Government and the public, were our fears to be practically realized. The Council has made a very clear and decisive representation to the Imperial and Local Governments on this subject, and it now remains for those who are responsible for this flaw in the medical administration of India, to set their house in order ere it is too late. I feel it my further duty, however, to press upon the consideration of the members of the local medical services, the duty of continuing steadfast to their posts, and loyally fulfilling their trust during these trying times of plague, and war and famine. I cannot, however, refrain from an expression of very earnest and loyal sympathy with the Government in the face of so many calamitous visitations and their attendant administrative burdens, although I feel that nothing can arouse or nullify the plain and honest duty of the State towards its long-suffering and truly loyal servants, the Civil and Military Assistant Surgeons, and the Civil and Military Hospital Assistants.

The old bugbear of private medical practice in India and the interference by State paid doctors with the same, has formed the subject of a representation to the M. W. P. and Oath Government. The case against military sur-

from, and the Government of India, in their public duties, according to directions, issued in any way to prevent the sale of private enterprises, could not have been able to do so.

It is very gratifying to us, as an Association, to find that the resolutions of our Council during the current year, on the subject of Calcutta Sanitation and precautionary measures for plague prevention and segregation, have merited the careful attention of the Bengal Government, and that in their resolutions concerning these matters, the State has referred to the valuable suggestions we set forth in our letter to Government. It is hoped that the Government will not withhold its practical appreciation of our efforts in the public weal, and that the distinction sought at its hands for our President and Vice-Presidents will be readily allowed.

With regard to the subject of Plague Segregation, I find that the action taken by the Bengal Government is not approved of by the Hindu and Mahomedan sections of Her Majesty's subjects, and I wish to publicly invite attention to the excellent suggestions of our Council contained in its letter to Government in March last, which I have abundant reason to know, are highly approved by the leaders of Indian Society in Calcutta, and which are capable of being carried into effect with the best possible results. The Council has under consideration further suggestions in connection with these matters which will be placed before the Government in due course.

I wish most emphatically to take this opportunity to refer to the most praiseworthy and zealous labors of our worthy Secretary during his stay in England. On the eve of his departure, the idea of approaching the authorities of the India Office and the War Office of London with a view to improving the position of the local medical services, and obtaining some promise for the larger utilization of local medical talent, as well as paving the way for a system of Medical Registration for India, was duly considered by us, and Dr. WALLACE, acting upon these thoughts, has not only loyally fulfilled a great commission, but he has proved by his personal tact and ability, that he could win the attention and sympathy and favor of the highest authorities in England. I have seen from certain documents in Dr. WALLACE's possession, which he is not as yet permitted to make public, that very important and valuable changes are likely to occur in the near future for the material advantage of the medical profession of India. We owe a debt of gratitude to our indefatigable and able Secretary not only whose official work but whose professional success in gaining the Fellowship of the Royal College of Surgeons demands our congratulations. (Applause.)

It now remains for me to announce, that under the provisions of Rule 11 of the Registered Memorandum of Rules and Regulations of the Indian Medical Association, the President, Vice-President, Secretary and Treasurer, having filled their offices for three years, must all retire from such positions this day, and with them the whole of the Members of Council, as is done annually. The Secretary informs me that all these gentlemen are willing to be re-elected, and it becomes your duty to-day to make your choice of officers for the coming year.

It is my duty also to mention you of the Secre-

tary's report to the Association, and to recommend with a quorum of our Council, that I ought to recommend this change to the interests of efficient work, and also having due regard to the many responsibilities with which our Council is freighted in relation to their own private vocations.

I now conclude my address with a very hearty wish that each and all of us will enjoy "A HAPPY NEW YEAR," and that the coming year will be one of great prosperity and success, not only to our Association, but to every one of its many members.

The President's speech was received with loud acclamation; whereupon Dr. CHAMBERS expressed his regret and the general regret of the meeting, at Dr. MUKERJEE's unavoidable absence, remarking at the same time that he knew of few men in his lifetime who were so faithful and punctual at their engagements as Dr. MUKERJEE. He referred to the number of those present at the meeting, and said that the busy and trying nature of the work of many of the practitioners, who were members of our Society, kept them from attending, but he wished to invite attention to the telegrams read to the meeting, and which came from gentlemen from all parts of India, who not only held high and honored positions in the profession, but were the elected representatives of large sections of our profession in the various provinces of the country. Dr. CHAMBERS said that the work of the Council, as shown by the Secretary's Report, was varied and important. He desired specially to point to that phase of it which dealt with the suggestion of a Medical Registration Act for India. He felt that the introduction of such an Act was very urgently required, on public as well as medical grounds, and he hoped to see every section of medical practitioners in India obtain due and proper justice from the carefully devised provisions of a Medical Registration Act for India. As Coroner of Calcutta, he had brought the whole subject of medical practice in India under the notice of Government officials, but up to the present time nothing had been done by the State. He desired also to add his kindest expressions of esteem to the memory of his friend and colleague, Dr. MONEY LAL DUTT, whose death the Council so much deplored. Dr. DUTT was an ornament not only to our profession, but to the whole Bengali community.

He desired also to add his vote of hearty appreciation for the excellent and remarkably successful work which had been so courageously undertaken and so loyally fulfilled in England by their Secretary, Dr. WALLACE, whose labors were for the good of the medical profession at large (loud applause and three cheers for Dr. WALLACE.)

Dr. CHAMBERS concluded his remarks by an exhortation to unity and good feeling and the certain success that awaited the toil and zeal of the Indian Medical Association.

The following Resolutions were then put to the meeting and carried unanimously.—

1. That this meeting hereby re-elects the present Officers and Members of Council to a continuance of their offices, in accordance with the Rules and Regulations of the Indian Medical Association.

Proposed by Dr. J. G. ANDERSON.
Seconded by Dr. BHATTARAI.

2. That this meeting approves of the alteration of Rule 11, by which the quorum for a meeting of Members of Council is fixed at six, and that Rule 11 is hereby altered, so that four members shall henceforth form a quorum.

Proposed by Dr. JOSEPHINE KATH GORE.
Seconded by Dr. H. W. JONES.

A vote of thanks to the Chair was

Proposed by Surgeon-Major FORSYTH.
Seconded by Surgeon-Major MORTIMER.

and was carried with acclamation.

COMMENTS AND NEWS.

HYGIENE AS A MATRICULATION SUBJECT IN INDIAN SCHOOLS.

We have received a Pamphlet from the pen of JOHN MURDOCH, LL.D., entitled "*Appeal to the Indian Universities for the Recognition of Hygiene.*" "This appeal," we are told in a Note, "is in support of a proposal to be laid before the five Indian Universities to make Hygiene a compulsory subject in the Matriculation Examination."

On page 12 of the Pamphlet we read "most of the Indian Universities have two science subjects for the Matriculation Examination, generally Physics and Chemistry. To be effectively taught both require good apparatus with which high schools are, in general, not sufficiently provided. The students at that stage have also an insufficient knowledge of English, under the circumstances little more than a confused smattering can generally be acquired. Such subjects should be transferred to the First Arts Examination. Instead of them let Hygiene and Physical Geography, including an outline of Astronomy be substituted."

We cordially agree with Dr. MURDOCH and the authorities quoted by him, that there is plenty of room for reform in our somewhat fossilised educational system, and we are quite as alive as he can possibly be to the practical value of Hygiene; yet we think it wise to hesitate before committing ourselves unreservedly in favor of the suggestion contained in the above sentence.

The amount of Hygiene that can be learnt without a previous knowledge of Physics and Chemistry must be very small, such a limited course may be very well for a school, but is it sufficient for a university Matriculation Examination? It is manifestly absurd to teach a youth that air consists of oxygen, hydrogen and nitrogen, or that a certain amount of CO₂ in the atmosphere is injurious, when he does not know what oxygen, hydrogen, nitrogen and CO₂ are, and how can he be expected to understand the principles of ventilation if BOYLE and MARRIOT'S and GRAHAM'S laws are a terra incognita to him?

Similar objections might be extended to almost every branch of Hygiene, were it necessary.

The objections formulated by Dr. MURDOCH against Physics and Chemistry appears to us equally applicable to Hygiene, and we have the same objection to "ineffective teaching" and a "confused smattering" as he has. Moreover, the difficulty of defective apparatus is one that can be surmounted.

We should be sorry to see Physics and Chemistry done away with, and particularly the former, which is certainly the most interesting to youthful minds.

In the curriculum of the student of medicine, Hygiene occupies an important position, but it comes late in the course after Physics, Chemistry, and Physiology have been mastered; and such, we think, is its natural and proper place.

We do not, however, see why Hygiene of such a limited scope as is possible under the circumstances, should not be added to these sciences for the Matriculation Examination.

We notice that the Matriculation subjects are not the same at all the Universities, and that seems to show that those presumably best qualified to judge, find considerable difficulty in deciding upon what subjects are the best; and this is a point upon which we do not feel it our duty to express an opinion.

We think, however, that it would be a mistake to admit Hygiene to the exclusion of Physics and Chemistry.

ANTISEPTIC PROPERTIES OF BILE.

In this age of scepticism and investigation, many of our most cherished ideas have received their death blow, nothing is held sacred, and now we note that the apparently well established idea that the bile possessed antiseptic properties has received a rude shock, if not its quietus at the hands of Dr. MATO ROBINSON. To this effect he adduces evidence as follows:—

In a case of biliary fistula, when bile was absent from the intestine for fifteen months, no irregular fermentative processes followed.

BLACK has demonstrated that the bile in cases of disease of the gall bladder or bile ducts always contains micro-organisms.

When the flow of bile along the ducts is arrested, micro-organisms often invade the gall bladder. CHARCOT and GOMBANET demonstrated the presence of organisms within it after ligaturing the common duct in dogs. This was confirmed by NETLER in 1886, who found that 24 hours after aseptic ligation of the common duct in dogs, organisms, both staphylococcus and bacillus coli communis, could be cultivated from the bile.

Mr. C. B. LOCKWOOD found streptococci and other organisms, but no ameba coli in an empyema of the gall bladder. NETLER found staphylococci and streptococci present in pathological human bile, and MARTIN, GILBERT and GIBODE and BOUCHARD have found the bacillus coli communis in the bile in cases of inflammation of the biliary passages. GILBERT and GIBODE found typhoid bacilli in the pus from a case of empyema of the gall bladder which came on as a sequence of enteric fever. CHIASSE investigated systematically a series of 23 cases of typhoid fever. With the exception of 3 cases, one of which was in the infiltrative and two were in the necrotic stage, he obtained typhoid bacilli invariably out of the gall bladder; it is probable that they enter by the bile ducts. There is no doubt that the bacilli multiply in the gall bladder, and it is possible that they may be responsible for post-typhoidal cholecystitis, for gall stones and also for relapses of the disease.

Normal bile is, however, generally sterile, this was proved by NETLER in 1884.—(*Lancet*.)

LEPROSY OVERCOME BY ISOLATION IN THE MIDDLE AGES.

ALBERT S. ASHMEAD, M.D. of New York, writes as follows.—"In the Middle Ages leprosy spread in every country of Europe and continued to spread until strenuous efforts were made to bring the diseased parts out of contact with the healthy community. In this no charity or regard was had to the victims of the scourge; the weak of the same majority alone was considered. It is from this point of view that it behoves us also to judge the conduct of the church. The Order of Lazarus was founded and leprosetories built in great numbers. The work and purpose of the order were to segregate and govern the afflicted and dangerous part of humanity. The thing was necessary, was an unavoidable consequence of the resolve of healthy mankind to remain so, and it was not so much charity as one might believe. The community wanted this work to be done, and who could do it but the church?"

"But, according to Dr. EHRLICH, Secretary-General of the Berlin Leprosy Conference, the church might have been spared these worries and these dangers, for isolation is not necessary, as these Middle Age people believed, who through isolation, were fortunate enough finally to overcome the disease.

"It is not certain that the growth of civilization since the Middle Ages has rendered the spread of leprosy impossible. We cheerfully admit that it cannot overwhelm people who

are clean in their habits, and consequently their dwellings, mostly of their bedding, living in apartments, sometimes from the inferior animals, etc., as it did our ancestors of the Middle Ages, whose life was no very different. Yet some danger still exists, and the spread of leprosy in various parts of Europe, and in parts which I venture to say are cleaner than the leprosy houses of Norway and Iceland, proves that the disease has not lost, under circumstances, its vital stamina; it seems to stir itself with remarkable vigor, and to be able to take advantage of any elbow room left to it.

"If enforced isolation and a permanent committee of official delegates do not come out of the Congress of Berlin—and Dr. ELLERSS does not want them to—that Congress will have been held for nothing, or at least only ad maiorem *Ehleri's gloriam*."

RUSSIAN IMPRESSIONS OF THE PLAGUE IN BOMBAY.

SAYS the *Lancet*:—"At a largely attended meeting of the Kist Medical Society, Professor VUISOKOVITCH recently gave an account of his expedition to Bombay to study the outbreak of plague. The Russian Commission, of which he was the head, had made a careful study of the epidemic from the clinical, bacteriological, and other aspects, and the general impression they had gathered was that although plague is a very severe disease, yet it is easier to deal with and control than some other diseases such as diphtheria or cholera. The plague bacillus dies quickly if completely dried up and it cannot live long in water. The disease is spread from man to man directly or by the medium of fomites; it is in fact a purely 'house-disease.' The part played by rats in spreading it is still doubtful. The most successful measures against the spread of the epidemic have been the following: the searching out of cases; their segregation in hospitals; removal of the healthy from an infected house; disinfection of the house and contents, examination of persons arriving at, or departing from, any district; and an eight or ten days' quarantine. Unfortunately these measures met with resistance in an unenlightened community; consequently it is of more importance to endeavour to keep the infection out of a country or district. This is not difficult if proper precautions are taken on the frontier. Professor VUISOKOVITCH stated that neither YERSIN's nor HAFKIN's prophylactic inoculations had proved to be quite satisfactory. In monkeys neither gave more than ten or fourteen days' immunity. The best results followed the injection of a fresh agar cultivation, killed by heating to 60°C. for one hour. YERSIN's serum had given very encouraging results as a curative agent. Among 150 patients so treated the mortality had, it is true, been 40 per cent., but it would probably have been less could many of the patients have been seen at an earlier stage of the disease."

A RONTGEN SOCIETY.

RONTGEN photography has now a society of its own which was inaugurated under the presidency of Professor SILVANUS THOMPSON, F. R. S., who in his address related the history of the discovery, and gave an account of recent work done in connection with it.

The rays possess electric and chemical properties. When discovered, they appeared to constitute a new kind of light somewhat resembling invisible ultra-violet light waves but differing from them in several respects. They possess a remarkable power of penetration and can neither be reflected nor refracted. They differ from all known kinds of electricity in refusing to be deflected by the magnet.

It is nearly two years since they were discovered, and but little progress has been made in that time. Improvement in the tubes have reduced the time of exposure, special

films have been devised by photographic methods, as long as no glass interferences; ten dense diagrams can be imprinted simultaneously or superimposed films.

It is suggested that by the aid of these rays the blind might in some cases be made to see, but experiments up to date have not been successful, and of course where the optic nerve is destroyed there could be no hope. In certain cases the retina of the normal eye does possess a faint perception for the rays.

A Tesla's induction-coil was exhibited, giving high-frequency oscillatory discharges direct from any ordinary electric supply with small expenditure of energy. When one of Tesla's own tubes is excited with this machine, the emission of Rontgen rays is so intense that standing 50 feet away from it one can still obtain on a luminous screen the shadow of the bones of one's hand.

THE CASE OF MALONEY *OVUM* RICHARD AND THEIR RECENT DOINGS IN CALCUTTA.

At the recent meeting of the General Medical Council of Great Britain in London, one of the minor items of business was the consideration of the case of WILLIAM ROBERT NUTTALL MALONEY, of Roden Street, West Melbourne, in the Colony of Victoria, registered in England 3rd March 1886, as Lic. Soc. Apoth. Lond. 1885, who had been summoned to appear before the Council to answer the following charges as formulated by the Council's solicitor:—

The matters charged against Mr. MALONEY relate to public advertisements by him in Calcutta, Melbourne, and Belfast, and also to his conduct in associating himself with a so-called medical electrician (Richard) and in practising and conducting in public a medical electrical treatment; and it is complained against him that he seeks to attract patients by a system of extensive public advertisements of his name and address and qualifications, and of the said treatment as practised by him, in and by which persons in need of medical aid were invited to consult him professionally and adopt the said treatment, and that the advertisements systematically published by him were of themselves of a character discreditable to a professional man.

Mr. FARRER said that Mr. MALONEY had been summoned, and in reply had sent certain letters of defence. The matter had been brought to the notice of the Council by the Royal College of Surgeons of England, who had removed Mr. MALONEY's name from their list of Members. He submitted to the Council, specimens of the advertisements as well as a newspaper account of a meeting held in the Ulster Hall, Belfast. In one of his letters Mr. MALONEY suggested that he had been sufficiently punished by being deprived of his place in the Membership of the Royal College of Surgeons of England. As to the electrician (Mr. RICHARD, with many aliases) with whom he had been associated for a time, he had fled the country when his antecedents became known. Mr. MALONEY further said, that his qualifications, had been inserted in no advertisement with his knowledge. He explained his non-appearance before the Council with the statement that he was standing for re-election as a member of the Legislative Assembly of the Colony of Victoria.

Mr. BRYANT gave some account of the experiences of the Royal College of Surgeons of England with Mr. MALONEY.

The Council on the clear evidence before it, found the charge proved, and adjudged Mr. MALONEY to have been guilty of infamous conduct in a professional respect, and directed the Registrar to erase his name from the Medical Register.

WIDAL'S TEST FOR TYPHOID FEVER.

GURARD (*Journal of the American Medical Association*) from an analysis of the results hitherto obtained, makes some interesting observations on WIDAL's method of diagnosing typhoid fever.

The test, he says, is by no means specific in the strict acceptance of the term; it has certain limitations in its practical

usually within 48 hours, and the appearance of the reaction is not infrequently delayed.

The precautions to be observed relate to (1) the violence of the typhoid cultures employed; (2) the dilution of the serum; (3) the time limit for the reaction.

The culture should be of a high and healthy degree of virulence and the inoculi actively motile; the dilution should be in the proportion of at least 1 to 10, with a limit of 15 minutes for the reaction to appear.

It should be remembered that the reaction may be due at times not to a present but to a past case of typhoid so mild that it has been entirely forgotten. The absence of a reaction does not necessarily exclude typhoid fever, as the reaction may be delayed till late in the disease, the test should be applied several times when the results are negative.

The best way to obtain the serum is by a cantharides blister. There can be no doubt that in the hands of the expert bacteriologist the test will give valuable assistance to the physician, although it is sometimes wanting or indecisive.

THE FLAGELLATED FORM OF THE MALARIAL PARASITE.

DR. W. G. MACCALLUM, of the John Hopkins Hospital, Baltimore, publishes some interesting observations on the above. The theories put forward up to the present time by LAVERAN, DANILEWSKY, MAXIMOW, MANSON, SAKHAROFF, and the Italian school have not, he says, obtained general evidence; his own observations were made on crows, which are very generally infected with the *haeteridium* of Lappe.

In fresh blood, only the mature forms undergo any change; they become rounded and extruded from the corpuscle, both in fresh blood and in stained specimens two forms can be distinguished; the protoplasm of one is granular and opaque of the other clear hyaline; the latter alone becomes flagellated.

The granular forms lie quiet and are approached by the flagella which have torn themselves free from the hyaline organisms. One of these plunges his head into the granular organism and wriggles himself inside; a second flagellum cannot enter the same body.

The admitted flagellum is at first active and churns up the contained pigment, soon it becomes quiet, in 15 to 20 minutes a cornal process appears at one side of the organism, the pigment collecting at the opposite side, the process grows and the pigment condenses, fill the organism and assumes a fusiform shape. The spindle-shaped organism moves forward twisting on its long axis and displaying amoeboid contortions; it destroys the red corpuscles in its path and the hemoglobin escapes.

In an intense infection a great destruction of corpuscles occurs; sometimes leucocytes fall victims. Nothing definite can be said of the ultimate fate of these forms. It is suggested that they may be the resistant forms that escape from the body during life.

Phenomena of a somewhat similar nature were observed in human blood.

IS DIABETES CONTAGIOUS?

A CONSIDERABLE number of cases of the simultaneous development of diabetes in husband and wife, has raised the question of the possible contagion of this disease. M. BOISUMEAU discusses this subject at length in his *Thèse de Paris*, 1897. The disease does not, as a rule, appear late in married life.

In one of BOISUMEAU's cases it attacked the husband in the end of five years, and the wife a year later; the husband died and the widow married again, and at the end of two years she had given diabetes to her new husband. Other relations

exist in which it is noticed that the disease passes from one generation to another, and sometimes from one sex to the other.

In one of BOISUMEAU's own cases it attacked the wife twenty-nine years after marriage.

The husband is generally attacked first; the length of time between the attack of the one and that of the other varies from three months to sixteen years.

According to FARRER MANE there are two theories to account for "Conjugal Diabetes": (1) The similarity of the mode of life, and of diet, and the fact that the two share alike in misfortunes; (2) a true contagion.

The second has received support from SHOWN, SCHWITZ, TENSER, CHAMBERLAIN, and MARIN.

The following two cases given by BOISUMEAU are suggestive of contagion: A man, who was the son of a diabetic and affected with diabetes, lost his first wife from diabetes; he married again and his second wife got the disease. In the second case, this man's sister, a diabetic, had as her first child a diabetic son, she married a second time, and her second husband became diabetic.

M. BOISUMEAU advances no theory to account for the contagion or its mode of conveyance.

ENGLAND'S POSITION WITH REGARD TO TROPICAL DISEASES.

GENERAL satisfaction is everywhere being expressed as to the step taken by St. George's Hospital and St. Mary's Hospital, London, in instituting a course of lectures on tropical diseases, to be delivered by Dr. MANSON; this step has been taken not a moment too soon, and it is a sign that the medical teaching bodies in Great Britain are having their eyes opened, like Great Britain generally, to their duties to the Empire on which the sun never sets.

In the matter of Tropical disease, England has fallen sadly behind the times. The English text-books are probably the worst in the world on the subject; we have nothing in our language which at all approaches the French treatises on diseases of hot climates by KILGOUR and KILGOUR, both French Army Surgeons. DAVIDSON's medley of compilation "Hygiene and Diseases of Hot Climates" is a very second-rate affair compared to it; and, it may be observed, that all the recent work in it of any value is borrowed from the Continent.

There was a time when we had an English School of Tropical Medicine connected with such justly honored names as BUDD, ANKERLEY, MOOREHEAD, MACLEAN, etc. these be amongst the ancient, but the modern where are they?

It is curious to observe how far medicine is behind the allied sciences as regards the climatology and distribution of disease; it is easy enough to obtain the most exact information regarding the physical geography, the geology, the meteorology, the fauna, the flora, the ethnography, etc. of almost any part of the world, but the climatology and distribution of disease has not yet been worked out in the same thorough manner.

Our Government does not appear to recognize the immense importance of encouraging medical research, nor have we any wealthy medical bodies which push the question. And it is with a feeling not akin to satisfaction that we see some of the most important bacteriological work in India in the hands of aliens.

DEATH THROUGH FAULTY DISPENSING.

THE death of a Superintendent Surgeon at Delhi from an overdose of strychnine due to the carelessness of a dispenser is extending the quality ordered in the prescription, attention to the class of man to whom the dispensing of drugs is too frequently confided, and the security.

It ought to be illegal to permit anyone to undertake the responsibility of making up prescriptions without passing some test, the unfairness of this custom its risks, its objectionableness from every point of view, except that of the proprietor's pocket, who pays wages little better than those of a coolie, ought long ago to have raised a storm of resentment to force the legislature to wipe it out. True, throughout Great Britain unqualified persons are permitted to dispense drugs, but they are on a higher scale of civilization; the responsibility is more apparent to them; they have more to lose and are more certain of losing it, and if they by mistake should poison the poorest of the poor, the Coroner's inquest may be depended upon for bringing the culprit to justice.

It is unfortunately not at all certain that accidents of this kind are very uncommon amongst the poor of this country.

Another case has since occurred at Rawal Pindi, the victim being Mr. FRANCIS, Secretary to the Rawal Pindi District Board.

THE COMPARATIVE INTELLECTUAL CAPACITY OF MEN AND WOMEN.

SIR WILLIAM TURNER, at the meeting of the British Medical Association at Montreal, has been ungallant enough to bring prominently forward, once again the old assertion that because the average brain of man weighs more than that of woman, therefore man possesses a greater amount of brain power than woman. This is a delicate subject, and one that might well be let rest at a time when women are making such gigantic strides in every direction.

The gross methods of tare and tret are not altogether convincing when applied to such intangible things as intellectual attainments.

Man, as a rule, has of course more muscular tissue than woman, therefore he has more muscular power, he is, in fact, a bigger brute and therefore has more brute force: it follows that a larger portion of his brain is taken up in controlling and directing these forces, and there is nothing to show that the residue, which we may assume to be connected with the higher qualities (though the assumption in many cases may seem to be extravagant) is any greater than the corresponding portion in woman.

In discussions of this kind, the fair sex will soon be quite able to take care of themselves; at present they have a powerful supporter in Professor DARKEWITZ.

CHEMISTRY OF BACTERIA IN THE INTESTINAL CANAL.

THE following are some of the conclusions, drawn by A. L. GILLESPIE, from a series of elaborate experiments upon "The Chemistry of the Intestinal Contents, and the Influence of the Bacteria Present:—"

1. The reaction of the contents of the stomach and intestine is *acid throughout*.

2. Two classes of organisms, mutually antagonistic, are present: (a) Acid-producing and unable to liquefy gelatin; (b) alkali-producing putrefactive bacteria, capable of liquefying gelatin. The ammonia formed by the latter often unites with the acid due to the former, to form ammonium lactate, a salt favorable to the growth of either.

3. Normal or increased acidity of the stomach contents favors the destruction of the less resistant putrefactive bacteria.

A low gastric acidity has the reverse effect, and might thus cause indigestion. On the other hand, the low acidity, by encouraging the growth of the acid-forming bacteria, may ultimately increase the acidity of and lessen the putrefactive decomposition in the lower part of the canal.

Herein lie hints for the treatment of that very troublesome complaint dyspepsia, *Verré; Sup.*

STATE-PAID DOCTORS AND THEIR MONOPOLIES IN INDIA.

The important subject of the monopoly by State-paid doctors of private practice in India, must soon engage the serious attention of the Supreme Government, as it is impossible for the higher authorities to view with unconcern, the irresistible claim for protection which the private practitioner has plainly proved is his just due from the State in the matter of his legal rights to earn his livelihood, and in the clearer light of the other side of the shield, namely, that State-paid servants should only perform State duties, a principle which is recognised and acted on in every other department of the State except the Medical Department. This great question is intimately associated with another important anomaly in medical matters, namely, the monopoly of State civil work by military surgeons. The inconsistency of the position, for the purposes of argument and justification, which has been hitherto assumed by the Government for officering our large metropolitan public hospitals by military surgeons, namely, that these officers were intended as a Military or "War Reserve," turns out to be almost as chimerical as it is false, for who has not observed the fact, that while there has been a great outcry in India about the pressing and urgent need for the services of Military Surgeons in the present frontier war, when every I. M. S. Surgeon has been drawn away from civil duty, the Military Surgeons who are "lent" to our large metropolitan public hospitals, though their places might easily have been filled by independent physicians and surgeons of excellent qualifications and experience, all these military officers, we say, were permitted to hold their snug and lucrative civil posts undisturbed. How efficiently might not their hospital duties have been performed by men both willing and able to take them up. How readily might not the services of these Military Surgeons have been set free as a veritable "war reserve," but strange to say, the perquisites of these war-reserve men, as general medical practitioners, was too strong an incentive to treat the much vaunted principles of the Indian Government, as being not worth the paper they are printed on. And so this anomaly flourishes in Calcutta, Bombay and Madras. Imagine one of these Military Surgeons of this so-called "War Reserve" being allowed to hold a civil appointment in Calcutta, not as a doctor, but as an Examiner in Oriental Languages! Could any farce be more ludicrous, and could any stronger argument be adduced to prove the utter weakness and falsity of the reasons upon which the Government bases its claim to perpetuate an anomaly that is so harmful to the public services. We sincerely hope that the question of our public hospitals being officered by open selection from the medical profession, as they are in every country, save India, will engage the active and earnest attention of the public and of the Council of the Indian Medical Association at an early date.

THE DISPOSAL OF TYPHOID DEJECTA.

A DISINFECTANT of the present day, is a means of rapidly and effectually destroying the evacuations in cases of infectious disease. There is only too much evidence to show that the practice of passing them into drains is fraught with danger, while their disinfection or destruction in private houses cannot be relied on.

In some manufacturing towns in England where the pollution of water and removal of refuse, at the same time, is done in special pits, colored roof or green up every house where a typical case is known to exist. This pit is charged with a powerful disinfectant and fitted with an air tight lid; it is frequently changed and the contents sent to the destructor.

An apparatus was exhibited at Newcastle in 1893, called the "Newcastle destructor" designed by Dr. ARMSTRONG, Medical Officer of Health, Newcastle-upon-Tyne, and Mr. W. G. LAURE for effectually dealing with these evacuations.

This apparatus, which consists essentially of a hermetically sealed iron vessel of a capacity of 50 gallons in which evacuations and other infected liquids are boiled under steam pressure, was used in the Cholera Hospital at New-castle during the prevalence of the disease, and found to work well.

The makers are Messrs. GODDARD, MANNY, and WARNER, Nottingham.

STATE INCONSISTENCIES IN MEDICAL MATTERS.

It is alleged that the Government of India has under consideration a scheme for the increase of pay to Military Hospital Assistants. How is this allegation, which is announced with some measure of authority, to be reconciled with the fact that the Government of India only a few months back recorded its inability to allow the college course or school-training of these same Hospital Assistants to continue beyond three years? The period of study was not only reduced from four years to three, but three important subjects, viz., midwifery, jurisprudence and hygiene, were excised from the curriculum. This was done on the score of economy, and the measure was held to be imperative from financial considerations. The pity saving supposed to be effected is not only prejudicial to the best interests of the State, but a positive injury to the individual launched into medical practice partially equipped. By a recent enactment we find Hospital Assistants classed among "Qualified Medical Practitioners," and that being so, the curtailment of his sphere of usefulness by the restriction in his education must be deplored. His academic training will no longer place him even on the same footing as the vernacular licentiate in medicine and surgery. He will be an anomaly in the medical world and a hybrid of the dresser-onn compounder type.

PROMOTION STOPPED FOR MILITARY ASSISTANT SURGEONS.

We often wonder if it has struck the Director-General's Office as strangely singular and unjust, that the present method of over-stocking the junior grades of the Military Assistant Surgeons' Service is resulting in a very real grievance to the members of these grades. The authorized strength of the lower grade of the Bengal Branch is 35. It stands at present at 76.

This means that promotion from this grade will involve a period of 7 to 8 years' waiting. How crushingly this will be felt may be seen by the following statement. A lad completes his course at college at 20 or 21, he then gets a salary of Rs. 50. He is 26 or 31 before he gets Rs. 85, at 37 he gets Rs. 110, at 43 he gets Rs. 150, and when he has completed 29 years' service or when he is 43 or 44 years old, he receives the magnificent salary of Rs. 300 per annum! We doubt if the Director-General's Department has ever had this handicap placed before it. If there is any condition likely to set up chronic discontent in the present badly paid staff of the Military Assistant Surgeons' Service, it is this unhappy stagnation of promotion. This state of things emphasizes the paper of the memorial of this department that promotion from grade to grade be made to depend on a certain number of years of service, as holds in every other department.

NEW DEVELOPMENTS IN FORENSIC MEDICINE.

There is no knowing to what extent speculation in medicine may not extend. One of the latest developments in Forensic Medicine is M. MAGNIEN's method of determining the date of death of an individual by an anatomological examination of the different genera of insects which attack the dead body in the course of its exposure; and the following is a very suggestive example of the practical utility of the idea.

Early in May 1895, the body of an unknown man was found dead in a lonely spot with a bullet hole in the skull. The decomposition of the body was far advanced, adipocere was formed, and in places the bones were partly bare. Body and clothes swarmed with larvae of pyrophila casei, and were literally covered with large dipterous larvae and empty pupae cases. The police thought that the man had been murdered during the winter in a house near by. The presence of the dipterous larvae and pupae cases placed the date back to some time during the preceding summer. The body was subsequently identified as that of a man who had been seen near the spot during the harvest season of the previous year; he had also shown a revolver to several people. The revolver was found subsequently near the spot where the body had been found, and the case pronounced to be one of suicide and not of murder, as the police would have it.

MILITARY MEDICAL RESPONSIBILITY.

WHEN we read in a daily paper that the medical arrangements were admirably carried out by General so-and-so, one is at first inclined to think that a mistake has been made. This, however, is not the case. The General Officer Commanding is really the person who is responsible for the health of the troops, and this responsibility is only too frequently multiplied by the way in which that official either does not ask for or tacitly ignores the advice of his responsible adviser—the Principal Medical Officer Under the circumstances it seems rather a pity that a little knowledge of sanitation is not considered a necessary qualification for a General, as their ignorance of, or contempt for the rudiments of this science, must be held largely responsible for the outrageous amount of sickness amongst the troops at the front. It is a pity their duties in this respect cannot be brought a little more home to them, but as long as "Correspondents" at the front consider it their whole duty to throw dust in the eyes of the public, and carefully hush up anything of an unpleasant nature, nothing can be done. It is only too well known that the tales these "Correspondents" tell by the bedside are very different from what appears in their papers, and ever so much more interesting.

THE PHYSICIAN AND MORALS.

SAYS the *Medical and Surgical Reporter*:—"A physician who cannot assimilate morals into his being can never expect to amount to much as a man. In other words, a physician as a man is measured by the depth of his moral nature, and not by the pretensions to professional greatness with which he would veneer his real self. It is for this reason that many men seemingly great are really small. They are out of harmony with true success, because they are out of harmony with their better selves. They play at greatness, for they cannot achieve it. They array themselves, as does a child, with the symbols of greatness—such as affixing to their names L.L.D., Ph. G., etc., with the vain hope that the submitted may with reverence bow to their stupendous learning. They interview themselves in the daily press, present the vast array of their accomplishments (largely imaginary), have themselves selected as Surgeons-General to Cuba—all on paper, however—with the same vain hope that some

THE CALCUTTA HEALTH OFFICERSHIP.

At a special meeting of the Calcutta Municipal Commissioners, held on the 31st instant, Dr. J. NIELD COOK, at present Health Officer of Madras, was elected Health Officer of Calcutta, *vice* Dr. SIMPSON. Only three candidates were proposed. At the first ballot Dr. CAYLEY, who is now on his way out to India as one of the medical officers selected at home for plague duty, tied with Dr. NIELD COOK. A second ballot being held the votes ran : Dr. NIELD COOK, 30 votes ; and Dr. CAYLEY, 18 votes.

NEW MEMBERS OF THE INDIAN MEDICAL ASSOCIATION PROVIDENT FUND.

The following have joined the I.M.A. Provident Fund as associate members since our last issue :—

C. S. Brown, D.G.M.C., Assistant Surgeon, Station Hospital, Rawal Pindi.

Dr. Mirza Mohammad Masoom, Calcutta.

George Chatham Ringrow, M.D., Assistant Surgeon, Bai Mathai and Sir D.M. Petit Hospitals, Omercurry, Bombay.

Faisalilah, C.M.S., A-52 Native Field Hospital, Fort Lockhart.

Dadabhoi P. Pestonjee, Officiating Civil Surgeon, H.H. the Nizam's Civil M. Service, Kureemnugger Dispensary, Hyderabad, Deccan.

SHORT ITEMS.

Vaccination returns for Bengal increase apace. Even backward districts such as Cuttack and Chittagong show considerable advances upon past records. Several districts, notably in Northern Bengal, show decreases, but this is due chiefly to prevalence of famine and inability to defray the small vaccination charges. It is satisfactory to note that vaccination by human lymph is dying out. In Dr. Dyson's opinion it will soon be altogether superseded in Bengal by the vaccine lymph method.

The question of a vote of censure on Dr. Weir, proposed by Dr. Bahadurji, came on for discussion again at the meeting of the Municipal Corporation of Bombay the other day. It was resolved by a majority on an amendment, that the Corporation, while recognising the strenuous efforts made by the Health Officer to deal with the bubonic plague, regretted that he should not have fully recognised the gravity of the situation when the first cases of plague occurred in the town.

A Nursing Association for the Punjab has now been started. A meeting, we believe, has been held at Government House, under the presidency of Lady Mackworth Young, when the following business was transacted :—To elect a Governing Body, appoint a Working Committee with power to make rules and start working, to decide a place where the Home shall be located, appoint a Lady Superintendent, and to decide on the number and class of nurses to be obtained from up-country and the Nursing Association in England.

In a recent despatch the Government of India pointed out the desirability of holding in abeyance the appointment of one of the three proposed Sanitary Officers during the period in which Surgeon-Major A. M. Davies, A. M. S., will remain attached to the office of the Principal Medical Officer, Her Majesty's Forces in India, in order to meet the urgent necessity for competent bacteriological investigation in cases of severe outbreaks of enteric fever.

The Government of India have sanctioned the grant to Military Assistant Surgeons of all grades, while on plague or famine duty, of any acting or charge or house allowance which they may have been drawing at the time of their

deputation to such a duty, and which they would have continued to draw but for such deputation, in addition to the deputation allowances permissible under the rules.

It is announced that the monthly *Army List* for December and January will not be published, pending a complete revision, which, we presume, will appear in February. This announcement would seem to indicate that a re-arrangement of the existing *List* is not all that is intended, but a complete reorganisation, foreshadowing important changes in the constitution of the army.

Dr. Lloyd Jones, who is in charge of the general plague hospital, Poona, recently invited by public notification all who had sick relations or friends in the hospital to come and visit them on Wednesdays and Sundays. The effect has been that large numbers now go on these days to see their relations, whom they are able to talk to from a short distance.

The following officers of the Army Medical Staff are coming out for a tour of service in this country :—Surgeon-Major E. L. Mansell, Surgeon-Lieutenant-Colonel W. T. Johnston, Surgeon-Captain A. Watson, Surgeon-Captain C. A. Young, and Surgeon-Lieutenants E. G. Forrest and A. H. Waring.

At the December Doctorate examinations at Brussels, two ladies from India passed the three examinations for M.D., and obtained their diplomas, namely, Miss Blong and Miss L. Edith Sykes, L.R.C.S., Edin., and L.R.C.P. Edin., the latter with distinction.

In addition to the Health Officer of the Bangalore, Cossipore, Chitpore and Manikotla municipalities, it has been decided to appoint an Assistant Health Officer for each, as the area of the three municipalities is too large for one officer.

Her Majesty the Queen has been graciously pleased to nominate Dr. James Little, of Dublin, to succeed Dr. William Moore as the Crown representative of Ireland on the General Medical Council for the next five years.

Brigade-Surgeon-Lieutenant-Colonel T. H. Hendley, O.I.E., has returned from turlough in England, and has assumed the office of the Presidency Surgeon, Jeypore, and Administrative Medical Officer in Rajputana.

Surgeon-Lieutenant-Colonels G. Hall, J. Duke, and J. McConaghey, I.M.S., of the Bengal Establishment, have been selected for promotion to the rank of Surgeon-Colonel.

Surgeon-Captain E. S. Peak, I.M.S., reverts to Military duty from the date of making over charge of his duties under the Government of Bengal.

Veterinary Captain H.T.W. Mann, A. V. D., and four trained assistants, have been named for service in the British East African Protectorate.

The Secretary of State has sanctioned the selection of Surgeon-Major D. Prain to succeed Dr. King as Superintendent of the Botanical Gardens, Calcutta.

A scheme as under the consideration of the Government of India for materially improving the pay and prospects of Military Hospital Assistants in the four commands.

Brigade-Surgeon-Lieutenant-Colonel Fawcett, Madras Medical Establishment, has been selected for promotion to the rank of Surgeon-Colonel.

THE ANGLO-INDIAN CAUSE IN ENGLAND.

FRANK RICHMOND TO DR. JAMES E. WALLACE.

A grand conference of the domiciled European and Anglo-Indian community was held at the Calcutta Town Hall, on Thursday, the 23rd December 1907, at 8 P.M., under the auspices of the Anglo-Indian Association. The hall was artistically decorated with bunting and banners, floral devices and lovely foliage plants, while the spaces between the magnificent pillars were hung with mottoes, such as "Unity is strength," "The Anglo-Indian Cause," "Sabbars to Britons in India," and others. There was a very large and fashionable gathering of ladies and gentlemen, so that the body and both side aisles of the hall were filled. It was clear that the Directors in announcing that the meeting was to welcome Dr. WALLACE had struck upon a popular call, for the response was a most representative gathering, who throughout the proceedings displayed a keen and enthusiastic interest in all that was said and done. On the platform were seated a score or more of the Directors of the Anglo-Indian Association. Punctually at 9 P.M. the Hon'ble Mr. M. C. TURNER, who had undertaken to fill the Hon'ble Sir GRIFFITH EVANS' place at the meeting, was voted to the chair, and was introduced in a few well-chosen words to the audience, by the Very Revd. Father V. MARCHAL, the Officiating President of the Association.

The Chairman then addressed the gathering as follows.—

Ladies and gentlemen,—In making a few introductory remarks before going to the business of the evening, I must ask your kind indulgence in having been called upon at the last moment to fill the place of that distinguished gentleman and accomplished speaker, Sir GRIFFITH EVANS, who has met with an unfortunate accident, compelling him to forego his engagement to preside this evening. Further, having my time fully occupied during the day, I have been unable to give the consideration that the subject of this meeting deserves. But in glancing hurriedly through the report of that very important deputation, which in July last waited on the Secretary of State for India, I was struck with two very important facts which were brought into special prominence by Dr. WALLACE, (cheers), namely, that domiciled Europeans in India and those who have British blood in their veins, amount to about one million, and of this number some 25,000 have enrolled themselves as citizen soldiers. In this country citizen soldiers form a very important reserve force, and should it be ever necessary to call them out, they will prove to be a most efficient body, and a substantial aid in time of necessity. (Loud applause). It seems to me a most extraordinary fact that although the State are willing and glad to avail themselves of your services as Volunteers, they will have nothing to do with you as paid soldiers. (Applause). Time will not allow of my going into details, but I am bound to say that I think the employment of domiciled Europeans and Eurasians as soldiers is a subject which deserves most careful consideration on the part of the State (Loud applause). It is, as we all know, now-a-days, a matter of extreme difficulty to find employment for our own (hear, hear), and if we receive no encouragement from those in power, how can we expect to launch the

young generation out into the world (Applause). I earnestly trust that this question may receive the serious consideration of the Government of India. (Hear, hear). I would say to those gentlemen who so ably advocate the cause, stating plain facts and figures, and do not go in for political agitation; do not ally yourselves with any political party in England, but rely on the justice of your cause, and I am sure you will receive the hearty sympathy of Englishmen throughout this country (Applause). As President of an Association which numbers many of your kindred among its members, I can certainly say that you have our complete sympathy and will have our support when it is needed. You have done such good service to the country in the past, and there is no doubt that you will do good and faithful service in the future. (Applause). As we have a great deal to get through this evening, I think we must now begin business. (Loud applause)

The Chairman now called upon Dr. WALLACE to address the meeting.

Dr. WALLACE, who rose amid loud cheering, said.—Mr. Chairman, ladies and gentlemen, I am sure it must be a source of real gratification to the Directors of the Anglo-Indian Association to find this spacious hall filled with so large, so representative and so brilliant an audience. This fact in itself bears eloquent testimony to the interest that exists, and now seems so intensely emphasised, in the great cause that has attracted so large and influential a gathering of the domiciled European community of this metropolis. It must be an incentive to further zeal and enthusiasm in the Anglo-Indian Cause, to find such a wide and general response from the community to the "call to arms," issued in the public press at such short notice, and in spite of so many counter-attractions. However, here we are, and before I go further, I wish to express our sympathy with Sir GRIFFITH EVANS, who had so kindly promised to preside at this meeting, but who, by an unfortunate accident, was prevented from doing so. I wish also to express, on behalf of the Directors, our earnest thanks to the Hon'ble Mr. M. C. TURNER for having so generously consented to take Sir GRIFFITH EVANS' place at considerable personal inconvenience to himself. I desire also to publicly acknowledge the indebtedness of this meeting to Messrs. HALL and ANDERSON, the well-known and flourishing drapers of this city, for their liberality in placing these handsome, costly and artistic decorations of this Town Hall at our disposal. I further desire a vote of appreciation and thanks, in anticipation of our excellent programme of music, to the ladies and gentlemen who are giving their time and their talents for our pleasure this evening. Now to the task set before me. The Directors of the Anglo-Indian Association have asked me to speak to you of the work I did for our people in London. Well, this is a duty I have already performed; for I spoke freely of my humble doings in England, at the public reception which the domiciled British community of Bombay so generously gave me on my return to India three months ago. The proceedings of that meeting were very widely published in all the public papers of this country, and I feel I would be guilty of egotism were I to recapitulate my experiences. My earnest desire is that the cause we all have so much at heart—not individuals engaged in furthering that

cause, and is immediately brought forward and fully understood, and thus largely advanced.

The Anglo-Indian Cause is the burning question of the hour. It is the pivot on which hang the most important concerns of the Dominions British Community are centred. Our very existence and growth as a people and as a nation, depend on the manner in which every part of our community treats this great question. As I said before, the education, the numerical position, the social and political status of the Anglo-Indian people are matters on which the most wide-spread impression prevails throughout England, Scotland and Ireland. The disabilities and the hardships under which we labor, cannot possibly appeal to the sense of justice and right of Englishmen in the Mother-country, because they know nothing of us. And so long as this lack of information concerning us remains unsupplied and dormant, so long will our claims remain unrecognized and ignored. I am assured, however, of one great fact from my recent experiences in the House of Commons, with Members of Parliament with offices in the India Office and the War Office in London, and with numerous leading public men in England, Scotland, and Ireland, wherever I had an opportunity of proclaiming the Anglo-Indian Cause, I found eager, attentive, sympathetic hearers, who were not only willing to help us, but who put their promises to the most gratifying practical tests, by giving me very valuable aid. We have strong friends in our kinsfolk in the Homeland. We have friends in India too, but India and the Indian Government are almost powerless against the paramount dominancy of the India Office. That bureau is the great stumbling block to every reform for India, and for the people who live and work in India, only however if they belong to India. The India Office seeks unbounded power in patronage, and it means to have this at any cost. Not only must stores and provisions and manufactures of every description come from England through the machinery of the India Office, but all posts in the Indian service worth having, must henceforth be in the gift of that conclave of retired Anglo-Indian officials. Fired with this determination, the India Office has decreed that henceforth all posts in the higher sections of the State Services in India shall be given to men from England. No Englishman or his descendants in India shall ever get into the Imperial or higher Services, unless he goes to England. There is no longer need to highly educate our boys, for, under the circumstances, any sort of education will fit them for subordinate positions. They are doomed never to rise to the standard of imported Englishmen. And why? Not, because they are not fitted by merit or qualification or loyal service to do so, but simply because they are born and educated in India. The very idea of such a policy is preposterously unjust and cruel in the extreme, for it places a ban on the Dominions British Community of India by branding the accident of birth and education in the land of our adoption, as a stigma and a curse. Will Anglo-Indians quietly and uncomplainingly submit to such a policy? I read your answer in your faces. Never! We will and must protest against such injustice. We possess claims to the higher appointments of the Indian Services, and if Britishers are to hold such posts, then we insist that we are Britishers, and we claim the right to compete with all others on fair and equal terms. We cannot, and shall not, be forced to the wall in this matter. We must fight this battle of our rights and privileges in England. Once let it be known and felt by the British people that we are being wronged by the India Office and the Indian Government, no power on earth will then keep back the righteous and just repeal of our disabilities and the redress of our grievances. I therefore feel it my current duty to urge upon the Meeting to raise a Fund, for the purpose of sending a delegate to Parliament next year. The funds of men are needed in all enterprises, and for this movement, money will be required. Though we spent nothing on our last delegate, our

next representative will have to make his own larger bag, and his expenses must be met. I am sure our people all over India will cordially respond to this call, and the Anglo-Indian Patriotic Fund, and as I trust, with generous effect will be raised, to carry the whole movement, to enable resources to carry out our campaign. I feel that your hearts are in unison in this matter, that you feel the force of what I have said in your hearts, and that I only hope it will result in a very deep feeling in your pockets, and that the Fund will be an accomplished fact. (Loud applause).

The Chairman now asked Mr. T. O. LAMAR, Barrister-at-Law, to address the audience. Mr. LAMAR said:—

Mr. Chairman, ladies and gentlemen,—I wish to say a few words on the report of Government to the memorial presented by your Association on the 22nd May last. That memorial protested against the exclusion of persons educated in this country from the Financial Department (Enrolled List), Public Works Department, Superior Accounts Branch and Railway Department, Superior Traffic Branch. The replies of the Government of India to the memorial was subsequently approved by the Secretary of State for India. The gist of those replies was that the rule of exclusion was made "in the interests of efficiency." I am desirous of laying before you a few facts which will enable you to test the value of this plea.

I do not profess to be a sub-juncto, (know-all) and cannot therefore say anything about two out of the three departments named. But, in common with others in Calcutta, I know something of the Financial Department to which, therefore, I will confine my remarks.

At a certain time when owing to the impossibility of finding a competent financier in the Bengal Civil Service, a gentleman had to be sent out from England to deal with the finances of the country. Mr. WILSON, for many years Editor of the *Economist*; was brought out. At that time there was a clerk in the Financial Office named ROBERT HOLLINGSBURY. Shortly after Mr. Wilson's arrival and his assumption of the office of Financial Member of Council, he fell in with a pamphlet on the Income Tax, written by Mr. HOLLINGSBURY. It was so closely reasoned and showed such mastery of the subject, that the Financial Minister was much impressed with it. He said that the author was a thinker and had a head-piece, and that was the making of Mr. HOLLINGSBURY. He rose in the Financial Department until he reached the position of Assistant Secretary. He gave his days and nights to his work, and was distinguished for his great industry and research. His notes on financial questions were a repository of information, and the tomes of the office containing them, are still referred to for the assistance they afford. Mr. HOLLINGSBURY published besides a treatise on the Silver Question, two large volumes on the relation of landlord to tenant in Bengal. Besides his own original views which were clearly and forcibly expressed, the book contained official papers of great value, historical documents, which he had fished up out of the Metcalfe Library. The book to which he was not allowed to attach his own name, came out anonymously and fell still-born from the press. But it has furnished material in writing on the rent question, with material which have been used without acknowledgment. Mr. HOLLINGSBURY retired not long after on a special pension of Rs. 600 a month. I have no hesitation in saying that he was second to no official in the Financial Department. Mr. HOLLINGSBURY was entirely educated in this country in the old Parental Academy of Calcutta.

Again the Military Accounts of the Staff Department up-country fell into confusion and a competent accountant was required to put them right. The Finance of the day,—I forget exactly whether it was Lord Mayo or Lord Darnley,—selected for the work, GORDON KALLAN, a clerk in the Financial Department. Mr. KALLAN was accordingly deputed to the North-West, where his dis-

...the country, were sent out from many an obscure Russian home throughout the troubled tracts, and from many humble Russian homes, too, men who fought like heroes side by side with their British brothers, to restore British supremacy in India. To this day we have amongst us many Russian grandfathers and great grandfathers helped to win the Indian Empire, who are Bohemians in blood, in habits, and instincts, and proud of their great heritage. Who could such men be sent out from military service now? The financial distress of the country adds an additional reason for recruiting in this country. That it will succeed, there can be no reasonable doubt. Up to 1884, when the QANWELL scheme began, there were depôts in various parts of the country at which English and Russian recruits were enlisted. The recruiting sergeant at one of these depôts himself told me scores of men of the old high standard, Englishmen and Russians, being taken in. I understand that some of the latter have since been captured in England, and are signing to join the British Army in India, but may not do so—good matured soldiers as they are—under some absurd rule. I cannot say that any very large number of men would be obtained right off, but the saving of the transport charges, at least in the case of every body of local recruits, however small, is, apart from other grounds, a consideration that a financially strained country cannot rightly despise. Now mark what has gone on at home, while good recruits have been declined in India. From General FIELDING's annual report—he is the Inspector-General of Recruiting—it transpires, that for seven years past, owing to the difficulty of obtaining the kind of men wanted and formerly obtained, but now growing scarce, the standards of both chest measurement and height, have been gradually lowered—the former from 35 to 34.5, 34 and finally to 33.5; and the latter from 5 feet 7 to 5 feet 6, and 5 feet 5 and I think even lower. You will have notified from a telegram 3 or 4 days ago, that Lord Lansdowne at the War Office, was doing all he could to raise the status and improve the prospects of British soldiers in order to attract men. To this no one can possibly object. But while the strain lasts, and men of the old standard of height and chest measurement cannot be secured at home, why should not the right kind of men of the old type be enlisted in India as they were before? The answer that the system of linked battalions suits the Army everywhere but in India—the great training ground of our Army—is surely no answer. However, there is a striking exception. Men of African descent in the West Indies form West Indian Regiments. The idea of men of African descent, born in America, being European British subjects and claiming the right of enlistment denied to us, is a strange one. If the West India Regiment is an exception, why may we not claim some exceptions for this great country, backed as our plea would be by unanswerable arguments.

I have no doubt that this wrong—which is a wrong to Indians more than to ourselves—will be righted if we seriously set about righting it. We must agitate in England and tell the British people what we need and why we need it. Indian natives get much more than we do by innocent agitation. But there is one radical difference between their agitation and ours. In all their agitation,

I may add that Mr. HOLLINGHURST's successor, who has achieved distinction as an artist as well as Sir GEORGE KILLMAN's brother Mr. E. W. KILLMAN, who has lately had to retire from the Presidency of this Association, owing to failure of health, and who rose to be a C. I. E. and Assistant-General of Lahore, were both wholly educated in this country.

In the light of these facts I ask you, ladies and gentlemen, to say whether the efficiency of the Financial Department was impaired by their having these distinguished officers. Was it not rather greatly promoted; and, if so, why should the Government of India be debarred from employing local talent and from availing themselves of the services of a class who have proved themselves most efficient and serviceable.

The Hon'ble Mr. TURNER now called on Mr. W. O. MADGE, Secretary to the European and Anglo-Indian Defence Association, to speak to the meeting.

Mr. MADGE (who was received with cheers) said:—Apart from the honor of addressing you this evening, I have a pleasure in doing so that is all my own, and that no one can take from me. I am sure most of you will forgive me if I refer to it briefly. Eighteen years ago, at the First Annual Meeting of the Anglo-Indian Association in this very hall, it was my privilege to draft a resolution moving for a commission to go to England, to make known our needs as a community to the great English people. At many a subsequent annual meeting I have suggested the same step, and at the last annual meeting I suggested that advantage should be taken of Dr. WALLACE's visit to England, to entrust him with our commission. And now the dream of the past has become a fact. I recall all this for no purpose of self glorification, I do so merely to claim, as a long and careful student and supporter of such a movement, the knowledge to judge how it should be carried out, and I do this simply in order to point out how thoroughly Dr. WALLACE has done his work. As a later resolution will deal formally with this matter, I must only free my mind by saying that it could not have been better done, and that Dr. WALLACE has placed our community under an obligation that can never be repaid. (Loud cheers). And now as the special subject entrusted to me to deal with this evening, the recruiting of Anglo-Indian soldiers: there are two dangers to be guarded against, one the failure to give us any Anglo-Indian recruiting at all, the other to reduce us to the level of native sepoy. A proposal of this latter kind was once seriously made, and if I could only show you the passions of resentment with which it was refused, you would understand why we cannot be made native soldiers. You remember the stirring words of the late Lord Laurence in greeting the Princess of Wales:—

Normans and Saxons and Danes are we!

But all of us Danes in our welcome of thee, Alexandra!

It is almost a shame to parody these beautiful words, but I am impelled to say:—

Britons, Anglo-Indians and Normans are we!

But all of us Britons in devotion to thee, Victoria!

(Prolonged cheer.)

When the Indian Mutiny swept like a blast of evil wind

or want of it—I say it with some regret, but the thing should be said:—there is an undertone of ill-feeling. Demands are made in the interest of particular classes of agitators rather than in the interest of the great mass. Now there is no such stuff in our thoughts. We believe and maintain that the Government of the country must remain British, and a British tone must pervade it. All we demand is that if we can help in maintaining this necessary British tone, as past history abundantly proves that we can, there is no reason why we should be excluded from serving anywhere. Keep the tone and standard of the civil administration in the British Army as high as possible, let there be no lowering of standard anywhere. Only let us take our place, when we show ourselves fit, beside the men from home. (Loud applause).

Professor ROWE, M.A., of the Presidency College, also addressed the audience in connection with his extensive acquaintance with Anglo-Indian youths, and he commended their intellectual and physical abilities as being equal to similar classes of youths in England.

The following programme of music was rendered during the speeches and the passing of the various resolutions:—

Pianoforte Solo.	Helmath—Klange	..	Mr. H. A. Stark, B.A.
Song	..	"Oris pro nobis"	.. Mr. H. Moreno.
Vocal Duet	..	"Larboard Watch"	.. Dr. J. R. Wallace, M.D., and Mr. J. S. Zemin, F.C.U.
Song	..	"Good Night"	.. Mrs. J. S. Zemin.
Song	..	"Lum tum-di-diddly-um"	.. Dr. T. J. Walte.
Song	..	"A rose in Heaven."	.. Mrs. H. E. Gaboko
Violin Solo	..	Belle's Bohemian Girl	.. Miss Kate Kirkpatrick
Duet	..	"A Nation's Glory"	.. Misses Nellie and Millie Forbes Mitchell.
Song	..	Your Voice	.. Mrs. Carr Turnbull.
Song	..	Love's Nocturne	.. Miss Grace Wollaston.

GOD SAVE THE QUEEN. (SUNG BY THE ENTIRE AUDIENCE)

The following Resolutions were placed before the Meeting:—

1. That this meeting of the Domiciled British Community of Calcutta recognises the paramount necessity for the existence of Associations in all the large centres of India, having for their objects the advancement and protection of the interests of the domiciled British community of India (Europeans of all nationalities and their descendants being included in this designation).

Proposed by Mr. JAMES CLEGHORN, C. E.
Seconded by Capt. C. V. PRICHARD.

2. That this meeting endorses and approves of the aims and objects of the existing Anglo-Indian Associations, and emphasises the urgent need of union and persistent action by the community represented by these Associations and the formation of a Representative National Council.

Proposed by Mr. W. G. J. SMITH.
Seconded by Mr. G. LOMNER, M.A.

3. That this meeting approves of the inauguration of the Imperial Anglo-Indian Association in London, to protect and advance the interests of the domiciled British community of India (including Europeans of every nationality and their descendants) and fully recognising the need and importance of such a representa-

tive body in London, this meeting expresses its earnest hope that all the Anglo-Indian Associations of India will co-operate with the Imperial Anglo-Indian Association, and duly authorise that body, to represent their corporations and to act on their behalf as common demands.

Proposed by Mr. W. H. KIRKPATRICK.
Seconded by Mr. H. A. STARK, B.A.

4. That this meeting earnestly calls upon all members of the Domiciled British Community to unite together for the defence of their common interests, and with this object in view, to aid in inaugurating an Anglo-Indian Patriotic Fund, to defray the expenses arising out of an organised representation of their cause in England.

Proposed by Dr. BUSH HART, M.B.C.V.S.
Seconded by Mr. J. ZEMIN, F.C.U.

5. That this meeting is strongly of opinion, in view of the excellent services hitherto rendered by the Domiciled British Community and their descendants, in the administration of the Government of India, that the members of this community have earned a rightful claim to a fair share in the Imperial and Provincial Services of India, and that they should have the acknowledged right to be officially regarded as the Domiciled British Community of India, and therefore the further right to compete for the purely British services in India, on equal terms with competitors from the Home Land.

Proposed by Mr. C. F. OLIVER, B.A.
Seconded by Captain B. LUNGLEY, R.N.

6. That this meeting of the Domiciled European and Anglo-Indian Community of Calcutta, held in the Town Hall on Thursday, 23rd December 1897, cordially appreciates and approves the various measures that have been adopted by Dr. JAMES ROBERT WALLACE, M.D., F.R.C.S., as the delegate of the Anglo-Indian Associations, for the advancement of the interests of the Resident British Community of India, by suitable representations of their cause to Parliament and to the India Office in London, and this meeting records its hearty thanks to Dr. WALLACE for his disinterested and praiseworthy labours on behalf of his countrymen during his stay in London.

Proposed by the Very REV. FR. MARCHAL, S.J.
Seconded by Mr. L. W. DEJEUZ, B.A.

7. That this meeting desires to express its special thanks to Mr. HENRY J. WILSON, M.P., and to Captain PIRIE, M.P., for their valuable assistance in promoting the representation of Anglo-Indian claims in the British Parliament, and it desires further, on behalf of their community, to record its grateful appreciation of the sympathy and kindness shown to Dr. WALLACE, the delegate of the Anglo-Indian Associations, by the authorities at the India Office and the War Office of London.

Proposed by Dr. J. G. ANDERSON, M.D.
Seconded by Mr. C. P. GAGUE, C.S.

The Meeting was closed by a vote of thanks to the Chair proposed by Dr. J. R. WALLACE, M.D., seconded by Mr. E. C. KEMP, M.A., by three hearty cheers given for Dr. WALLACE and by the whole audience rising to their feet and singing

GOD SAVE OUR QUEEN.

Special Report by J. K. GUEST,
Reporter to "The Englishman."

Current Medical Literature.

IMMEDIATE.

The Serum Treatment of Leprosy.

DR. BUZZI, of Berlin, has had the opportunity of attending one of the rare cases of leprosy which happen to come from foreign countries to this city, and he has described it in the *Deutsche Medizinische Wochenschrift*. The patient was a boy, fifteen years of age, who came from South America in 1891. He showed marked symptoms of maculo-tubercular leprosy, such as hypertrophy of the skin of the forehead, the nose, the cheeks, the chin, and the ear; on his face there were disseminated tubercles of about the size of a pea. Tubercles were also present on the extremities, and the skin, especially of the trunk, was covered with brown pigmented spots. The usual internal and external remedies proved useless. New tubercles were formed and the patient's general state became worse. Injections of Koch's tuberculin performed in 1892 were very injurious, for new eruptions followed and there was suppuration at the places where the injections were made. In 1897, when Dr. CARRASQUILLA, of Bogota, advocated the serum treatment of leprosy, Dr. BUZZI obtained a supply of the anti-leprosy serum, and from February to June twenty-six injections of from 0.3 c.c. to 3-25 c.c. were given, the whole quantity employed being 42 c.c. The injections were given at first twice a week, then once a week, and afterwards once a fortnight only. The tissues round the place of the injections used to become oedematous; the injections themselves were rather painful, but no suppuration followed. Well-marked collapse ensued twice. Two or three hours after the injection the temperature generally rose and within eight hours reached 39° or 40°C. (102.2° or 104°F.), the commencement of the rise being marked by a rigor. During the night the temperature became normal after free perspiration, but the following day it rose again. The injections were nevertheless continued. Dr. BUZZI observed in the leprosy tubercles the same alterations which were described by Dr. CARRASQUILLA as a sequel of his injections. The tubercles at first became swollen and were then partially absorbed, the hypertrophied tissues of the extremities decreased in size and the skin became smoother, the ulcers of the palate and uvula healed up and those of the nose improved; the patient's weight also increased from 89½ kilos. to 45½ kilos. (from 87 lbs. to 100 lbs.). The treatment has now been discontinued for about four months. Some new tubercles which appeared during and after the treatment were spontaneously absorbed. Although it is still uncertain whether the improvement will continue, the injections of serum have so far yielded results which are much better than those obtained by any other method of treatment.—*Lancet*.

Writer's Cramp.

EDWARD W. WRIGHT states that writers' cramp has three chief theories regarding its pathology:—

1. A local disease; a weakness in some muscles permits the overaction of their antagonists, which increases the spasm.

2. A reflex action; the result of the stimulation of the sensory nerves in the act of writing.

3. A central origin; a want of proper balance in the co-action of the motor centres concerned in the action of writing.

The latter seems to be the most satisfactory. In the muscular group of the eyes we can have all of the causes present. If the cause be present in the ocular muscles that produce writers' cramp in the hand of writers, can we not have cramp in the muscles involved in reading?

Constant tension of all the ocular muscles at close range for long periods of time, with a weak individual muscle or pair of muscles, with overtaxed nerves, and an exhausted cortex, are the prominent conditions that would lead to spasm or cramp of the ocular group of muscles.—*Univ. Med. Jour.*

Acetonuria.

NEBELTHAU relates an exceptional case in a woman who was much wasted. There was no evidence of visceral disease, and there was no sugar in the urine. The breath smelt of acetone, and the urine gave a most marked reaction of aceto-acetic acid. There was vomiting, and the vomit also contained acetone. An investigation was made into the metabolism of this case. In the first or comparatively fasting period, acetone, aceto-acetic acid, oxybutyric acid and ammonia were found. The acetonuria was not so marked as in a severe case of diabetes, but exceeded the amount usually present when the patient is dieted. The amount of urine was small, and hence a considerable excretion of acetone occurred through the lungs. The urine contained during this period albumen and casts. Cases of intestinal intoxication have been recorded where there has been albuminuria with casts as well as acetonuria. The total nitrogenous excretion was very low in the first period; the patient had taken very little food for some three years past. In the second period the vomiting was controlled by means of cocaine and suggested treatment, and a sufficient amount of food was taken. Now there was considerable nitrogenous retention, and the weight increased. With the sufficient nutrition the smell of acetone in the breath, the reaction with ferric chloride in the urine, and the increased ammonia excretion disappeared. It seemed to be a case of hysterical anorexia and vomiting with consequent inanition. Thus a considerable excretion of acetone (4 g. in the day) may exist without producing much disturbance of the general condition.—*Brit. Med. Jour.*

The Dreams of Hysterics and Epileptics.

AN Italian alienist (DR. SANZIS) has been making an interesting study of the dreams of hysterical and epileptic patients and claims to have found that out of 56 cases of grave hysteria, 35 were fair dreamers, 10 great dreamers, and 8 did not dream at all. Frequent dreaming was associated with light sleepers—the more profound sleepers not dreaming at all. In 45 cases of *grand mal* there were only 10 dreamers. In 21 cases of *petit mal*, 16 were great dreamers, 4 fair dreamers, and 1 (a sleep-walker) did not dream at all. In the hysterical, dreams of pain and anguish were most frequent than those of fear and terror, and then those erotic or otherwise pleasurable. As to the character, the dream of large animals predominated, while in alcoholism the dreams are of tiny animals, "microscopic." The dreams of epileptics were fewer from terror and animal fears, and erotic dreams were more constant. With epileptics the dream vision is brief and simple; in hysteria it is romantic and complex, and in this relation it is suggested that the sex is a determining factor—the hysterical subjects being women and the epileptic men.—*Pac. Med. Jour.*

Night Terrors.

BRAX, after critically discussing the existing theories on favor nocturnus in children, declares it to be a disease by itself, which is closely allied to the conception of neurasthenia, i.e., "an irritable weakness." Following this, a description of the characteristics of the attack and their demonstration is given. The sudden jumping up of the patient out of its sleep—symptomatic especially in colic—has no relation to night terrors. The etiology as well as the treatment is that of neurasthenia, and the latter should be pointed in the direction of nutrition and education.

Observations on the Treatment of the Rectum.

FRANKLIN, in the *Journal of Medical Science*, gives the following observations in a paper written a year ago:—

1. Operate upon all cases of fistula where there is sufficient standing or retention to heat the wound. Always divide the fibrous membrane at the bottom of the tract and pack the wound to the bottom for the purpose of healing by granulation.

2. Always open abscesses early to prevent fistula in ano.

3. If you operate on a fistula in a tuberculous patient, give him the benefit of the doubt.

4. Never fail to examine patients thoroughly for small arms leading out from the main tract, and for an associate stricture, which may be the cause of the fistulous tract.

5. Never cut the sphincter but once in any operation, and be careful and warn the patient of the danger of incontinence.

6. Confine the patient in bed, not trusting to the care of the nurse exclusively. Tuberculous cases should be an exception to the rule; give them moderate exercise and fresh air.

7. Physiologic rest is the first principle in the cure of all diseases.

8. In all operations involving the rectum it is good surgery to dilate the sphincter.

9. All cases of fistula in ano should be operated upon, and best by the knife, except in cases of Bright's disease, cancer, cardiac and hepatic affections.

Fractures of the Skull.

In a consideration of the permanent or later results of these fractures, Dr. WILLIAM N. BULLARD draws the following conclusions: "1. Out of seventy persons with fractures of the skull, thirty-seven presented no symptoms when examined some time later. 2. Only seven persons presented serious symptoms, and in at least four of these it is doubtful whether the symptoms were due to the injury. 3. The most frequent consequences found were headache, deafness, dizziness, and inability to resist the action of alcohol on the brain. 4. Out of the fifteen cases in which operation (trephining, etc.) was performed, twelve had no symptoms; in another it was doubtful whether the symptoms present were due to the injury; in another the symptoms were slight (headache rare, tension over the wound while lying in bed); the other was deaf, but had no other trouble. We are justified, therefore, in concluding, so far as our statistics lead, that those cases in which trephining was performed have shown much better results, as far as the symptoms discussed are concerned, than those in which no operation was performed."—*N. Y. Med. Rec.*

Dupuytren's Contraction of the Fingers.

FRANK brings forth several facts in support of the view that retraction of the palmar fascia is due to some predisposing constitutional condition, and that traumatism and external irritation play but a subordinate part as more exciting causes. The symmetry of the lesions, which is one of the most frequent characters of the affection, favours this view. Moreover, the contraction is often associated with general conditions marked by trophic disturbances. Rheumatism and beriberi have often been noted in the hereditary and personal antecedents of the subjects of this affection, and many authors have pointed out its occasional association with gout. It has also been observed, though less frequently, in diabetic patients. Allusion is made to its occasional coincidence with induration of the fibrous sheath of the penis, an instance of which is published by the author. Palmar contraction is sometimes met with in cases of nerve affections,

such as tabes, epilepsy, and general paralysis. The author recognizes the influence of various agencies, as only exciting, of traumatism, and points out in most of such influence the almost constant commencement of the contraction in the fourth and little fingers. A case, however, is here recorded in which the affection commenced on both sides in the thumb.—*Brit. Med. Jour.*

Wound of the Brachial Plexus: Successful Secondary Suture.

THE following case is recorded by Dr. HUMPHREY MARTIN:—A man was cut with an axe along the posterior border of the left sterno-mastoid muscle. The wound commenced one and-a-half inches above the clavicle and ran upwards and backwards for two inches. The surgeon who was called said that it was one and a half inches deep and had divided the nerves, but he only sutured the margins of the wound. Sensation was lost over the lower left side of the neck, the lower anterior triangle of the neck, and the area supplied by the descending cervical nerves, the outer side of the arm and of the extensor surface of the forearm, and the thumb and index fingers. At first the arm was useless, but a month afterwards the patient could flex and extend his fingers and move his thumb, but the muscles of the forearm were wasted. There was complete paralysis of the deltoid, biceps, coraco-brachialis, brachialis anticus, triceps, and scapular muscles. The pectorals were very weak. Supination and pronation of the forearm were very defective. The flexors and extensors of the wrist and fingers acted well to faradization, as did also the serratus magnus, infra-spinatus, and rhomboidel. The deltoid, supra-spinatus, pectoralis major, biceps, triceps, coraco-brachialis, brachialis anticus, and supinator radii longus gave no response. To the constant current the muscles supplied by the median nerve reacted when one rheophore was placed over the scar and one on the muscles, but not those supplied by the supra-scapular, circumflex, musculo-cutaneous or musculo-spiral nerve to the triceps. It was concluded that the cord formed by the union of the fifth, sixth, and seventh cervical nerves, just above where the supra-scapular nerve comes off, must have been divided. On the fortieth day after the injury a three-inch incision down to the posterior border of the sterno-mastoid was made, dividing the platysma and the deep cervical fascia. Some small nerves, probably the descending cervical, were seen. These were pulled backwards and by carefully deepening the wound the distal end of the cord mentioned was found. The proximal end which was slightly bulbous was found half an inch above this. The ends were trimmed and united by kangaroo sutures. Some recovery of motion and sensation was evident soon after the operation, and this steadily increased until the patient had a useful arm. When last heard of he had recovered power in all his muscles except the deltoid, which was improving, and he had regained sensation except in the area supplied by the circumflex nerve.—*Lancet.*

Flexion Cure for Scleritis.

P. BOHUEI reports ten absolute cures in fourteen cases of obstinate scleritis, treated by his method of forced anterior flexion of the body preceded and followed by massage at intervals of one to five days. Improvement commenced with five or six, and the longest time required was twenty sessions. When all other means have failed, he recommends this treatment, which is merely the forcible stretching of the nerves involved in the contraindication. He never uses chloroform, but advises it in extremely painful cases. Only one case resisted the treatment completely.—*Jour. Amer. Med. Assoc.*

Ligation of the Uterine Artery.

A method of securing the uterine artery safely and easily by ligation is described by **SHENIGOFF** and **SHENIGOFF**. By pulling the broad ligament forward and pushing the Fallopian tube backward, a triangular space is formed, in which an incision is made behind and parallel to the broad ligament. By dissecting downwards in the subperitoneal cellular tissue, in close proximity to the anterior layer of the broad ligament, the artery can easily be found and ligated. The authors assert that by thus stretching the broad ligament the ureter is located much deeper than the artery, and at the same time is nearer the posterior layer of the ligament, and can thus readily be avoided.

SHENIGOFF by this method has ligated the uterine arteries eight times, and in seven of the cases removed complicated uterine tumours, almost without any blood loss. The operation has once been performed for uterine hemorrhage due to fibroids, without subsequent removal of the tumour. Very large tumours render the operation more difficult.—*Edin. Med. Jour.*

Statistics of Eclampsia in Pregnancy and Labor.

HALBERTSMA has observed 109 cases, 49 being closely analysed. Of these 31 suffered during pregnancy, and 18 at the beginning of labor. In 7 eclampsia set in before the eighth month of pregnancy, all mothers saved, but 6 children lost, in the case where the child was saved incision of the os (**DUHESSEN's** practice) was undertaken. Of eclampsia later on, **HALBERTSMA** classes 5 as "light cases," 1 "moderately severe," 1 sufficiently peculiar to be set aside from the rest (spontaneous delivery, pneumonia, gangrene of the lung), and 17 as definite "heavy cases." Out of the 17, 2 are rejected on account of some uncertainty about treatment, whilst in 7 neither Cesarean section nor **DUHESSEN's** incision was practised, and all died, whilst in 8 when one or other of these operations was undertaken 6 were saved. **HALBERTSMA** here notes that 1 death followed Cesarean section, the first he ever performed, many years ago. It was done before the days of antiseptics and precise suturing of the uterine wound, 6 of the 18 cases of eclampsia beginning with labor are classified as "light," 13 as "severe," no less than three quarters being lost. None of the unfavorable cases underwent Cesarean section or incision of the cervix, and none received timely assistance from more common artificial resources. In 1 the pelvis was contracted; 1 patient was an old primipara. There remain 5 cases that were saved, in 3 incision of the cervix was practised, in the third chloroform and morphine were administered, and when the os was completely dilated the forceps was applied. **Halbertsma** favors this line of treatment, but states that should it fall the continuance of the fit will be more deadly to mother and child than Cesarean section.—*Brit. Med. Jour.*

Dental Affections and their Relations with the Genital Functions in Women.

M. JARON, in the *France médicale* for October 2nd, states that during menstruation or the days which precede it, patients often complain of pain in the teeth and in the gums. These pains are more frequent at puberty, at the establishment of menstruation. The teeth may be absolutely healthy or correctly plugged. The gums are tumefied and sensitive. Gingivitis may appear, with or without local causes, at the time of menstruation. Teeth that are spontaneously loosened are also sensitive on contact with instruments. Very often the patients complain of an increase of the salivary secretion.

*These pains may give rise to very disagreeable hallucinations in the ear, and they may be sometimes connected with a stomatitis dependent upon abnormal menstruation. All these troubles become attenuated or disappear, says the author, under local treatment, such as plugging the gums with moisture of iodine and washing the mouth with an emollient together with a proper medication to favor the appearance of menstruation.

The same symptoms are also observed in many women who have not menstruated or who have reached the menopause.

A menstrual period, continues the author, has been said to be a contraindication to the extraction of teeth, but in reality there exists but one contraindication of this kind and that is in hæmophilia, which is shown by an incessant tendency to various hæmorrhages, but, on the whole, such cases are very rare.

The unfavorable influence that pregnancy exerts on the vitality of the teeth renders the case of the mouth and of the teeth more imperative than at any other time.

During lactation the care of the teeth is no less imperative than during pregnancy, in order that a woman may be a good wet-nurse, her teeth should be kept in as good a condition as possible in order to enable her to chew properly.—*N. Y. Med. Jour.*

Some Points of Preventive Treatment in the Diseases of Women.

DR. A. E. GILES, writing in *The Hospital*, says that the first question here is of overstudy. Probably the average girl can acquire as much learning as the average boy, but to do so she requires bodily health and strength equal to his. Now the boy and girl work under different conditions, which, if ignored, lead to disaster. Let girls pursue their study, but more leisurely, they will arrive at the same goal, but a little later. Physically and emotionally a girl arrives at womanhood earlier than a boy arrives at manhood; this necessitates a corresponding saving of energy in some direction, and the direction in which this economy of energy is to be sought is in intellectual activity. Secondly, it should be impressed upon parents that premature emotional excitement is bad; sensational love novels should be avoided, and the "sex question" left dormant as long as possible. The idea that marriage is the only goal of a girl's existence should be discouraged for, while it may be true that in the role of wife and mother the average woman is seen at her best, the preparation for this position is best attained, not by directly aiming at it but by the development of physical health, by training of the mind, by breadth of thought and widening of interests.—*N. Y. Med. Rec.*

A Pedunculated Fibroma of the Broad Ligament Simulating a Large Salpingitis.

UNDER the above title **SINSTR** reports the results of a necropsy upon a woman who had died of phthisis. The uterus was of normal size, and carried an intramural fibroid projecting from its anterior surface and left side. The left tube was thickened and cystic at its outer end. The left ovary was surrounded by an inflammatory zone; it was cystic and was grooved on its outer surface for the reception of a pedunculated fibroma of the broad ligament as large as a chestnut. The fibroma was attached to the ovary in a way similar to that of the head of the humerus and the glenoid cavity. The pedicle was twisted. The right tube was dilated at its outer end and the right ovary was cystic. There had been no pelvic symptoms during life. Probably everyone would have concluded from an external examination that the fibroma of the broad ligament was a salpingo-ovarian. The inflammatory lesions were probably tuberculous.—*Brit. Med. Jour.*

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.

A New Theory of the Cause of the First Sound of the Heart.

Two of the chief events which takes place during systole, namely, the closure of the auriculo-ventricular valves and the muscular contraction of the ventricular walls, are regarded by many authorities as the source of the first sound. The results of QUAIN's latest investigations lead to the conclusion that none of these explanations are satisfactory. He points out that the auriculo-ventricular valves do not contain the necessary mechanism for the production of the sound, and from the fact that it can be heard independently of the existence and action of mitral and tricuspid valves, and that in some of the lower animals, especially reptiles, these valves exist only in a very rudimentary form, and that in such animals the first sound is distinctly heard, he concludes that "the weight of evidence is clearly against the possibility that the structure or the functions of the auriculo-ventricular valves is the source whence proceeds the first sound of the heart." Another reason for his rejecting the generally accepted theory for the first sound of the heart is that the feeble sound emitted by even large masses of muscles powerfully contracting is not to be compared with the characteristic booming of the systolic sound, and he points out that the contraction of the heart of a turtle removed from the body gives no such sound, even in a modified degree. Having thus considered the generally accepted view, he gives evidence to show that the first sound is produced by the impact of the blood driven by the action of the muscular walls of the ventricles against the block produced by the columns of blood in the pulmonary artery and aorta, which press upon the semi-lunar valves. His reason for this conclusion is that sound must be conceived to be a phenomenon resulting from resisted motion, and the movement of the blood is directed against a fixed and definite resistance, as that of the blood pressure in the aorta and pulmonary artery.—*Brit. Med. Jour.*

The Climacteric Period in Men.

ALTHOUGH there is no abrupt cessation of function in the male at all corresponding to the menopause in women, there is nevertheless a "critical period" in his physiological life, says the *Med. Press*. The change is one intimately associated with nutrition. The digestive and assimilative functions begin to slow down between forty and fifty years of age, and the organism, as a whole, undergoes a readjustment. If the digestion remain active while assimilation becomes less perfect, an increase in weight, due to accumulation of fat, takes place. If, on the other hand, digestion is the first to fail, symptoms of dyspepsia, with associated loss of flesh, characterize the period of transition. It is in athletic individuals of active muscular habit that the manifestations are most marked. A time arrives when lessened nutrition renders it impossible to maintain the normal activity of the muscular system. The eliminatory organs perform their function less perfectly, and the processes of dissimilation are hindered. The accumulation of the products of metabolic tissue change in the system reduces the vitality of the subject and indisposes him to the routine amount of exercise. If the subject fail to grasp the significance of these equations he renders himself liable to various functional disturbances which may culminate in organic disease of the organ or organs most exposed to the strain. Even if he yield to the pressure put upon him, it takes some time for the muscular and vascular systems to tone down to the reduced standard of vitality, and during the period of adjustment he is apt

to suffer from a variety of more or less distressing feelings, which not unfrequently determine mental depression. The change is not unlike that holiday spent in active physical exercise. There is the same want of harmony between nutrition and muscular exertion, but, in the waning adult, there is, of course, the factor of increasing arterial rigidity and general loss of tone on the part of the tissues. The so-called "critical period" is only critical in so far as the readjustment of the organism to changing conditions is interfered with. Those who have always led a sedentary life are less subject to these disturbances than the more robust and actively disposed. Once the harmony of the functions has been restored the individual resumes his normal existence, though on a lower scale, and he ceases to be liable to the visceral engorgements which are apt to result from "retrogressive irregularity."—*Med. & Surg. Rep.*

The Differentiation of Gonococci.

STEINSCHNEIDER gives his latest views on the subject. He first points out that the gonococcus will not grow on the ordinary cultivation media such as agar, gelatine, peptone, bouillon, etc., but can be cultivated on serum mixed with agar. The author confirms the good results obtained by SCHAEFFER by combining a watery extract of spleen with serum agar, on which the gonococci grow more abundantly and quicker. He thinks the use of serum spleen agar useful where a quick result is required, but owing to degeneration also taking place more quickly further cultivations are best done on serum media alone. STEINSCHNEIDER draws attention to other diplococci which microscopically resemble the gonococcus, especially KIEFER's meningococcus occurring in epidemic cerebro-spinal meningitis; this coccus, however, differs from the gonococcus in staining by GRAM's method, and in growing well on glycerine agar. He concludes by requiring the following conditions in order to establish a certain diagnosis of the gonococcus. (1) Treated with GRAM's method and a contrast stain, the gonococci are found in the cells stained by the contrast stain, but are not stained by GRAM's stain; (2) cultures grown on serum agar but not on agar alone; (3) diplococci obtained from such cultures do not stain with GRAM's method.—*Brit. Med. Jour.*

The Pathogenic Microbes of Pneumonitis in Diseases of the Eye.

WEEKS writes:—"Different forms of micro-organisms of pneumonitis are described and a resumé of the experiments of various investigators as to the influence of these micro-organisms upon the tissues of the eye and the inflammatory processes to which they may give rise. The evidence collected, the author says, is sufficient to establish the fact that the pneumobacillus of FRIEDLANDER is capable of producing grave ulcerative processes in the eye, and that the pneumococcus of FRANKEL (Micrococcus Pastueri, STERNBERG) has been observed as the pathogenic micro-organism in cases of tenonitis panophthalmitis, hypopion keratitis, conjunctivitis and probably in some cases of dacryocystitis. The contagious nature of pneumococcus conjunctivitis, although probable, is not yet fully proven, nor is it yet a fully established fact that acute conjunctivitis can be produced by introducing into the healthy conjunctival sac pure cultures of the germ; further corroborative evidence must first be obtained."—*Jour. Eye Ear & Throat Disease.*

PUBLIC AND DOMESTIC HYGIENE AND SURVEILLANCE.

Landlords and Drains.

QUESTIONS relating to drains have lately claimed a considerable share of attention from the newspaper-reading public. Complaint is made that the very laying of the drains is at fault, even when the surveyor certifies that all is right. A correspondent in a morning paper broadly asserts that in the district where he lives most of the houses built since 1891 "are not in accordance with the London County Council by laws as to the sanitary arrangements, nor with the deposited plans of the drainage." We need hardly point out that if this be so it is a distinct fraud, and that if the surveyor has certified to a new house being fit for occupation when he has not exercised due diligence to ascertain that it has been built in accordance with the plans deposited with the vestry, he runs perilously near being implicated as a participator in the fraud. There is no doubt that the practical separation between the surveyor's department and the health department of the vestries is a great evil, leading to plans being passed and buildings being erected which are soon condemned by the health officers. A case occurred, however, a few days ago which shows what power the sanitary inspector possesses, and how well supported he is by the courts in enforcing good sanitary work. In this case a man had taken a house subject to certain repairs and alterations being made. The plaintiff, a builder, was engaged by the agent to make these alterations, and during the progress of the work one of the city sanitary inspectors insisted on certain other work being carried out beyond that which appeared in the specification. The inspector spoke to the agent about it, and the work was done according to his directions. The landlord, however, refused to pay more than was in the contract. It was admitted that the inspector did not serve a written notice requiring the extra work to be done, but Mr. Commissioner KERR, before whom the case was tried, held that this was not necessary. It was, he said, no use opposing sanitary inspectors when they wanted necessary work done. There is another way out of such difficulties, however, which is sometimes adopted by landlords of the more wily sort, which has led a correspondent of one of the papers to feel serious qualms of conscience and to entertain grave doubts in regard to his duty towards his possible neighbour. He was in treaty for a house; he had, in fact, taken it subject to the report of his surveyor that the drains were in good order. The landlord had stated that they were in perfect condition. The surveyor, however, found them to be as bad as they could well be. On reporting this to the landlord, and asking if he would put them right, an answer was received to the effect that he would not consider the applicant any further as a possible tenant. "So far I am safe," says this correspondent, "but what of the tenant who does not adopt my precaution, and takes the house, as most people would, upon the assurance of the owner or his agent?" What, indeed? and what course should this conscientious correspondent take to warn prospective tenants? Clearly there is a death trap waiting for someone. Shall he stand idly by and see the innocent walk in, or what shall he do? The ethical side of the great drainage question threatens to be as complicated as the legal.

Condensed Milk in Infant Feeding.

C. G. KERLEY calls attention to the difference existing between the composition of breast milk with a $\frac{3}{4}$ to 4 per cent. of fat, a 7 per cent. of sugar and a 2 per cent. of proteids, and condensed milk which is usually administered in a one-in-twelve dilution giving a 0.5 per cent. of fat, a 4 per cent. of sugar and a 0.6 per cent. of

proteids. The deficiency of the latter is made up by the addition of cream, in the poorer patients by administering cod-liver oil after feeding. The proportion of proteids by the addition of the condensed milk to a meat broth; by boiling a pound of lean beef in a quart of water, until the liquid is reduced to a pint, this broth contains 0.8 per cent. of proteids. One part of condensed milk added to twelve of the broth makes a mixture of 0.5 per cent. of fat, 4 per cent. sugar and 1.4 per cent. of proteids, this with the addition of cod-liver oil to the diet to bring up the fat, answers very well for an infant three months of age. At six months the proportion should be one part of condensed milk to nine of broth, giving a 0.75 per cent. of fat, a 5 per cent. of sugar and 1.7 per cent. of proteids, this does until the age of nine months, when some of the proprietary infant foods may be substituted. His opinions in brief are: (1) In the artificial feeding of infants always determine as accurately as possible the percentage of the food constituents. (2) Condensed milk alone is an indifferent substitute for mother's milk, no matter what the age of the infant may be, (3) Condensed milk alone should not be given after the third month. (4) Condensed milk, fortified, may be made an acceptable diet for infants; alone, it is a food upon which a certain number of children exist until age or a changed condition allows of a better diet; and inasmuch as there is nothing to take its place among the very poor its value to them is inestimable.—*The Med. Age.*

Sufficient Complaint in Malpractice Case.

THE complaint in *OSWYTT v. STEWART* alleged that the plaintiff was kicked on the right leg by a vicious horse, and the same thereby broken and greatly injured. That, at that time, he called the defendant, a surgeon, and informed him of the manner of receiving such injury and employed him, as such surgeon, to examine such broken leg and ascertain the extent of the injury thereby caused, and to set the same, if broken, and to treat and heal the same, for whatever the injury was to it. That for that purpose the defendant undertook, as a surgeon, to examine the injured leg to ascertain whether the same was broken and also undertook to treat and heal it for whatever the injury to it was. That pursuant to said undertaking the defendant examined the leg in a negligent and unskillful manner, and failed to ascertain that the same was broken, or the extent of the injury to it, and treated and tried to heal the leg as though it was not broken, greatly to the plaintiff's injury, making him sick, causing him much pain and annoyance, and putting him to great expense, etc. The sufficiency of this complaint was demurred to, but the supreme court of Wisconsin holds that it contained in substance the averment which it has declared to be necessary in a malpractice case, and was entirely sufficient.—*Jour. Amer. Med. Assoc.*

Is Crime a Disease.

OF 394 thieves, 74 are dolichocephalic, 139 mesocephalic, 191 brachycephalic; of 107 homicides, 31 are dolichocephalic, 81 mesocephalic, 54 brachycephalic; of 92 sexual offenders, there are 18 dolichocephalic, 80 mesocephalic, 33 brachycephalic; of 64 swindlers, there are 9 dolichocephalic, 15 mesocephalic, 80 brachycephalic. A study of the individual indices shows a considerable proportion to be entirely outside of the physiologic limit. This is most marked among the sexual offenders, in whom the cephalic index was in itself absolutely pathological in about fifteen per cent.; that is to say, considering the antero-posterior diameter of the cranium as 100, then the transverse was represented by less than 75 or more than 87, the former being extremes of dolichocephalic and the latter of brachycephalic skulls. The brachycephalic skulls much predominated in the entire group of criminals.—*N. Y. Med. Rec.*

SYMPTOMS AND PHARMACOLOGY.

Medical Treatment of Strabismus.

Dr. Stryker treated in hospital during 1896, 197 cases, 146 recovered and 12 died. The temperature ran from 105° to the limit of the thermometer and in many cases was as high as 108° and 110°.

His treatment was as follows:—The ambulances were supplied with ice, which was put to the patient's head as soon as he was picked up. Upon admission the patient was immediately stripped, the temperature taken per rectum, and the body covered with a sheet, upon which were placed small pieces of ice. Ice water was dashed on the patient for 30 or 40 minutes. The most efficacious stimulant was the pouring from an elevation of a fine stream of water upon the forehead. This was continued for one to two minutes at a time and repeated. At the same time the patient was given forty minims of the tincture of digitalis hypodermically—except the full-blooded cases, which were bled.

When the temperature returned to about 104°, the patient was covered with blankets and hot bottles applied. This was done to prevent subnormal temperature and collapse. When consciousness began to return, whiskey was given. Strychnine was never given; convulsions were treated by chloroform, but they were rarely dangerous. In cases of prolonged unconsciousness, nourishment and stimulants were given by the stomach tube. Caffeine and whiskey were chiefly given, and in extreme cases hypodermics of whiskey, but never morphin. As death seemed to be the result of respiratory paralysis, artificial respiration was kept up for a long time, with surprising results. The after-treatment consisted of light diet, stimulants, fresh air, ice cap, and large doses of spirits of mindererus.—*Med. and Surg. Rep.*

Atropine

1. In no case of questionable diagnosis, in persons over forty should atropine be used.
2. In every case, while using atropine, except in threatened perforating ulcers, the tension of the eye should be taken daily.
3. In all cases, where it is necessary to use atropine as long as several weeks, an occasional instillation of eserine is a good safeguard.
4. That numerous cases of glaucoma are caused by the injudicious use of atropine there can be no doubt.—*Med. Brief.*

The Prevention of Consumption.

DR. B. W. RICHARDSON, in a late number of the *Asclepiad* states that an observation of the following rules will benefit those having a tendency toward pulmonary tuberculosis:

1. Pure air for breathing is the first rule for the prevention of consumption.
2. Active exercise, out-door as much as possible, is essential for the prevention of consumption.
3. Uniform climate is important for consumptives.
4. The dress of the consumptive should sustain uniform warmth.
5. The hours of rest should be carefully regulated by the sunlight.
6. Out-door occupation is preventive.
7. The amusements of consumptives should favor muscular development, and sustain healthy respiration.
8. Cleanliness in the broadest sense is of special moment.
9. Every precaution should be taken to prevent colds.
10. The diet of consumptive people should be simple, with full proportion of the respiratory foods.—*Lancet.*

Diabetic Tests.

THE simplest test for diabetes is to place a small piece of bright tin, which is kept over a candle flame until the urine has evaporated. If sugar be present the test portion of the urine will give the characteristic appearance and odor of burnt molasses.—*New York Med. News.*

Mix all together, shake well two or three times a day, and in four days, after.—*Chem. and Drug.*

THE ETIOLOGY OF "KALA AZAR": DR. GILES' CRITICISM OF DR. ROGERS' REPORT.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Through the courtesy of Surgeon-Captain LEONARD ROGERS, I am in receipt of his just published report on Kala Azar, and as the author of a previous report on the same subject, it seems more or less incumbent on me to state, for the information of the professional public, whether I see any reason to modify the views I am well known to hold on the subject.

I may say at once that, so far from seeing reason to recede from my original position, I find much in Dr. ROGERS' work to confirm the opinion set forth in my original report, as well as since then in your columns, *viz.*, that the increased mortality in Assam, which is known to the natives of that province as "Kala Azar," is due to the effects of ancylostomiasis acting on a population which is, and has for generations been, continuously poisoned with malaria, but I fail to see any reason for believing that the malaria is any worse than it always has been, so that it cannot fairly be considered the primary cause of Kala Azar.

Although I do not propose to occupy your space by a detailed criticism of Dr. ROGERS' report, it may be well to state shortly some of the grounds which compel me to refuse to accept his conclusion.

To begin with, Dr. ROGERS falls into the common fallacy of imagining that the number of ancylostomes found P. M.; or, at any given stage of a case, by expulsion by vermifuges, is any index of the number present at some previous period.

This fallacy has been repeatedly exposed by myself, and more recent writers on the subject, and lies at the root of most of the misapprehensions regarding the disease.

From a consideration of the usual methods of inspection, it is certain that infection on a single occasion must be exceptional, as the number of embryos capable of being introduced by the usual vehicles on any single occasion cannot be large. On the contrary infection, as a rule, must be little by little, and continuous. Further, not only are new recruits continually joining the forces of the enemy, but *per contra* a certain number are continuously being detached, so that the question whether an individual becomes seriously diseased or remains healthy, depends on the relative number of recruits and desertions.

Since leaving Assam, though my material has been somewhat scanty, I have enjoyed far better opportunities of continuous observation of cases than was possible there, and I find that the spontaneous passing of living worms is by no means so uncommon as is generally supposed. Further, in a very interesting P. M. I made on a case at Saharanpur I found, low in the bowel, a considerable number of dead ancylostomes so altered by digestion that I failed to recognize them. They were, in fact, picked out by the Hospital Assistant who was helping in the dead-house, and it was not till he had produced several that I had any suspicion of their nature. On microscopical examination, however, I found they consisted of the thin whitish envelope alone, with, in some cases, the buccal apparatus undetached. This digestion of the detached worms explains why they

were not seen in the stool. Some of the most overlooked after-effects of the administration of vermifuges, and make certain a point I have long supported, *viz.*, that there is a continuous passing out, as well as in, of parasites, and that if an uncomplicated case can be removed from its environment before fatal damage has been inflicted, it should tend to recovery. It accounts for the small number often found in cases long under observation in hospital, even when vermifuge treatment has been omitted, and explains completely the apparent want of proportion between damage done, and the number of parasites found which is so often observed.

Dr. ROGERS lays great stress on Surgeon-Major DOWSON'S observations as to the commonness of ancylostomes in subjects apparently healthy.

It has always appeared to me that, to any one who gave the matter a second thought, no more thorough confirmation of the validity of my conclusions could possibly be furnished than these valuable and painstaking observations, and yet we are asked to believe that in districts where the opportunities of infection are so widely spread that nearly 80 per cent. of the apparently healthy harbour a greater or less number of the parasites, the number of persons seriously affected will be too small to affect mortality. Surgeon-Major DOWSON, I am aware, is of opinion that these parasites are practically harmless, but in this matter he stands in the position of *Athanasius contra mundum*. Throughout the world in Egypt, Ceylon, and South America, wherever the disease is common amongst populations of low civilisation, all other observers are agreed that the disease is a source of a heavy mortality. How much greater then will its effects be amongst the malaria-ridden people of Assam.

Surgeon-Major DOWSON'S position, however, though utterly untenable, is at least consistent and intelligible, but the same cannot be said for the views held by Dr. ROGERS; for he not only admits the occurrence of fatal cases, but describes several observed by himself, and has further worked out a most ingenious and scientific method of differential diagnosis between the cachexia of ancylostomiasis and malaria respectively, which he admits are clinically with difficulty distinguishable. It is perhaps somewhat to be regretted that the test can be utilized by the few alone who happen to carry out with them a haemoglobinometer, and have the leisure to use it, but this is inevitable with the more refined methods of diagnosis, and I fear that this method can have little beyond an academic interest to the practical physician in Assam.

How any one can maintain so preposterous a position that in regions where the ancylostoma is so common that few escape entirely, a large number should not be fatally affected, will, I think, appear unexplicable to all who reflect that elsewhere observers are unanimous as to the terrible fatality caused by ancylostomiasis, wherever early and efficient treatment is not only available, but eagerly sought for. That the disease is not now so frequently fatal among the carefully watched coolies in Upper Assam is by no means surprising, but a very different state of affairs existed in this respect, in the times before the true cause of an alarming mortality was discovered by Dr. RUDOLPH. The Assamese alone, according to Dr. ROGERS, in some inscrutable way, nearly

always contrived to harbour just a sufficient number of ankylostomes to do him no harm and no more. While referring to the question of diagnosis between malarial and helminthæmia, Dr. ROGERS takes me to task for pointing out that the color of the sclerotic is a good diagnostic test between pure cases of malarial anemia and that due to ankylostomiasis, being yellow in the former and white in the latter. Dr. ROGERS goes to very unnecessary pains to show the test is not an absolute one, but every one who has passed beyond the text-book stage of existence knows no such signs have a really absolute value, and I still believe that this easily recognizable symptom will be of greater value to the practical physician in Assam, than the use of the hæmoglobinometer. Dr. ROGERS may yet discover that the indications of even such formidable instruments of research are liable to be misread.

Dr. ROGERS elsewhere suggests that the circumstance of my arriving in Assam during the cold weather led to "Dr. GILES' misfortune" (sic) in not recognizing malaria as the one and only cause of Kala Azar. Now whether we rate each other's conclusions as misfortunes or faults, I have little doubt that the fact that his study of the disease was mainly made at a time when the true cause of the enhanced mortality is masked by the seasonal prevalence of malaria, has much to do with the mistake into which he has fallen.

The cases he exclusively describes as Kala Azar, in point of fact, differ in no way from such as are met with in the daily practice of every Civil Surgeon who is stationed in any malarious part of India, and no one save those whose experience is limited to Assam or some other single locality, would regard such cases as in any way unusual or requiring any far-fetched theories of virulence and infectiveness for their explanation.

In this connection it is noteworthy that the only medical man resident in Assam, at the time of my own investigation, who had any extensive district experience outside Assam, supported my conclusions practically in their entirety. I refer, I need hardly say, to Dr. CAMPBELL, whose previous experience as Deputy Sanitary Commissioner in the N.-W. P. specially qualified him for the investigation of sanitary problems, and though he was subsequently disposed to assign a larger share to the malarial co-efficient than he did at the outset, it seems to me to be a matter of very little practical moment whether Kala Azar is considered to be ankylostomiasis complicated in the greater number of cases by malaria, or paludal fever complicated in 70 or 80 per cent. of cases with ankylostomiasis. The difference is rather verbal than real, but it seems to me personally to be better to consider ankylostomiasis as the primary condition, because it is this alone that has conferred infectiveness, and increased the normally high mortality of these unhealthy regions to a pestilential level.

All previous supporters of the purely paludal origin of Kala Azar saw that the infectiveness of the malady was a complete and fatal objection to their thesis, and accordingly labored to show that Kala Azar was not infectious, but here again Dr. ROGERS supports my observations; and those whom my arguments failed to convince on this point, are certainly left with no stand-point by the chapter Dr. ROGERS devotes to this subject in his report.

An ordinary man would indeed see at once that such a position is untenable, but Dr. ROGERS, like a medical Alexander, cuts his Gordian knot by announcing that Assamese malaria is infectious. In this he places himself at variance with not only the scientific, but the popular opinion of the entire world, and it appears to me that he advances no single fact or experiment wherewith to support this novel view, except that Kala Azar is undoubtedly infective, and that although he admits the ankylostoma to be astonishingly common in Lower Assam, he refuses to admit this to be the obvious explanation of the undoubted infectiveness of the condition. Dr. ROGERS, it is true, instances the fact that in Burdwan, some years ago, a somewhat similar condition prevailed to what is now known as Kala Azar, and that some who had to deal with the outbreak considered that it must be spread by infection. Ankylostomiasis is, however, as Dr. DOBSON has shown, very common in Lower Bengal also, and it is not unlikely that the Burdwan epidemic was due to the same combination of causes.

Bold as he is, Dr. ROGERS does not venture to suggest that all malaria is infective, as it is only the special breed which is found in Assam that requires modification to suit his special theories. He accordingly suggests that the malarial plasmodium has been so stimulated by the congenial environment it finds in Assam, that it has taken a leaf out of the bacterial library and increased its virulence till it has developed infectiveness. Now this characteristic of the bacteria is a very peculiar one and nothing of the same kind has, so far as I know, been discovered even among closely allied plants. The "*plasmodium*" malaria is, on the other hand, a protozoan, and therefore in no way allied to the bacteria, and to pre-suppose any close similarity of their mode of action is to adopt an analogy of the most forced description; and while it would perhaps be going too far to say that it would be as fair to argue from a cow to a cowlip, it would certainly be equally so to predicate the life history of a noctiluca from that of a diatome.

Our knowledge of these protozoal blood parasites is absolutely in its infancy, so much so that a large number of species are, like Dr. ROGERS special Assam ankylostoma, supposed to be quite harmless. As one of those who every year believes less and less the harmlessness of parasites, whether animal or vegetable, I look upon their supposed harmlessness as merely due to our limited knowledge of the health and disease of the animals in which they are found. What little we do know, however, tends to the conclusion that, as in the case of other animal parasites, their harmfulness is governed by quantitative rather than qualitative considerations. Their rate of multiplication bears, e.g., no proportion to that of the bacteria, and I cannot understand any one possessing any general knowledge of biology founding any argument from one to the other. Dr. ROGERS is at any rate, so far as I know, absolutely original in suggesting that the phenomena of increase and attenuation of virulence occur for the protozoon of malaria, but this is not the only point on which he possesses a certitude with regard to malaria, as yet unattained by the rest of the world. He states for example (p 200)—"We know (the italics are mine) that in the great majority of cases malarial fever originates from the inhalation of germs." Now however probable this

theory may be, I must submit that as yet we know absolutely nothing as to the exact route of infection, and that, to deal with the unsolved problems of malaria as Dr. ROGERS does, is a mere unscientific exercise of the imagination which can only result in confusion and error.

The only argument advanced by Dr. ROGERS, which requires any serious refutation, is that which he bases on the disappearance of Kala Azar from the tracts of country in which it was first noticed. How, he asks, could a disease such as anchylostomiasis disappear in this way? That it has actually disappeared I strongly doubt, though a noteworthy diminution of mortality may be accepted. It must be remembered however that emigration from infected sites from terror has taken place largely wherever Kala Azar has appeared, and although the fugitives will doubtless carry with them the worms that happen to be parasitic at the time within their own persons, they cannot carry with them the infection of the soil which alone can supply the new recruits requisites to conduct a case to a fatal termination. It will take some considerable period before the ova deposited by the transported parasites can effect the extensive infection of the soil of the new inhabited site requisite for the maintenance of cases. Moreover a little study of the literature of the subject should have taught Dr. ROGERS that helminthiasis wane and wax much in the same way as other epidemics.

But here, again, Dr. ROGERS' facts afford the strongest possible argument against his theories. An infection capable of being communicated by the kind of intercourse that subsists between an European and his punkah-wallah, as instanced by Dr. ROGERS, so far from being stopped by migration, would only be afforded opportunities for wider and more rapid spread. Against the spread of anchylostomiasis, on the other hand, short of the adoption of a complete and efficient system of conservancy, no measure can be effectual as migration, albeit the remote results of such a procedure may not be entirely satisfactory unless it be repeated as soon as there are signs of the soil of the new site being infected. To be thoroughly effectual, such migrations should be periodical, and never to sites already occupied by other village communities. Fortunately, however, a very short distance is quite as effectual as a long one, so that there need rarely be any necessity of going beyond the limits of the lands belonging to an average village.

If the methods of disinfection of sites, indicated in my report, were systematically adopted on each abandoned site, there is no reason why such a system of periodical migration and disinfection should not ultimately stamp out the disease, without the enforcing of any elaborate system of conservancy, which, though clearly the most obvious and rapid method of dealing with the disease, is, I frankly admitted in my Report, so much a counsel of perfection in the case of such a populace as the Assamese, as to barely come within the sphere of practical politics.

Another reason why a disease which spreads in the way anchylostomiasis does, should tend after a while to diminish, lies in the dying off of the unfittest. The explanation why, among the inhabitants of an infected site, certain individuals swallow embryos enough to kill, while others only take in a few, or escape entirely, can only be found in small differences of personal habits.

To take an extreme case, e.g., an European might live for years in a Kala Azar village and never come to harbour a single worm, and even among the Assamese there must be differences of personal cleanliness, for but for this, all persons living in an infected site would soon come to harbour an equally large number of the parasites. Those whose better habits have protected them during the earliest part of an outbreak, naturally are likely to remain healthy, and so an epidemic dies down.

Dr. ROGERS, of course, labors under the disadvantages inseparable from the scanty opportunities he has enjoyed of studying tropical diseases.

The 2½ years he had served previously to going to Assam had been passed in charge of a native regiment where one's patients are all persons specially selected for good physique and stamina.

Had he had even this amount of experience of district work, I feel sure he would not have found it necessary to contrive such an entirely new and original etiology to account for the every-day malarial cases which alone he consents to class as Kala Azar.

There has been a general tendency in criticisms on my own report to overlook the fact that throughout I assigned only a preponderating influence to anchylostomiasis, on the production of the complex chronic anemia known as Kala Azar.

In summing up my conclusions as to the etiology of the disease at page 66 of my report I remarked:—

"As will be seen, I am far from asserting that any and every case that will be produced as *Kala Azar* is necessarily anchylostomiasis, or that cases of malarial cachexia are otherwise than very common, for such cases are very common now, always have been, and it will be long ere they cease to be so. All I wish to convey is that the increased mortality is due to the anchylostomiasis, and to no other cause, and hence the answer to the question propounded at the commencement of the section, must be that if we take *Kala Azar* to be anything brought as such, *Kala Azar* may be anything, but that if we confine ourself to the cause of the present pestilence, the reply is that it is anchylostomiasis.

If, as it is to be sincerely hoped will not be the case, the term *Kala Azar* be retained at all, it should, I think, be confined to the cause of increased mortality, which has given rise to the term. The preferable course, however, will be to classify our cases under the headings of ordinary medical nomenclature, and to avoid entirely the use of such misleading terms as *Kala Azar* and *Beri-Beri*."

Pure cases of either cachexia are indeed the exception, and in many it is difficult to say which preponderates, but of the two main causes, anchylostomiasis is communicable and transmissible only by infection, while malaria is a disease of localities, or, to use the customary term, "climatic." As *Kala Azar* is undoubtedly communicable, it appears to me that this clearly indicates anchylostomiasis as the primary condition.

A further practical consideration is this:—We know practically nothing of the exact methods by which the malarial parasite gains access to its victims, and no one has as yet been able to suggest any method of protecting a person resident in a malarial region from its attacks.

On the other hand, the new and complete life-history of the first stage of the worm, which I was able to work out, makes our knowledge of its methods of access absolutely certain, and this knowledge assures us that it can be stamped out with complete certainty by efficient conservatism, and can be dealt with less completely by migration, disinfection of sites and other accessory measures which I suggested.

It seems therefore that it would be better to attack the enemy we know we can deal with, than to concern ourselves at first about its ally of whose strategy we are as yet ignorant, and against which at present we have no methods of defence.

At present it appears to me that the most promising line of investigation would be to try the experiment of putting into effect the various practical recommendations that have, from time to time, been made; as should they prove effectual, no better proof of the validity of the conclusions on which they are based could well be desired.

It would not be difficult to interleaf Dr. ROGERS' report with a detailed refutation of his views, but I fear I have already exceeded the limits of the Editor's available space and perchance of my readers' patience. I may add, however, in extenuation, that I do not propose to be drawn into any prolonged discussion on the subject as what I have said is, I think, quite sufficient to establish the entire untenability of Dr. ROGERS' position, and I doubt if any good purpose is ever served by a prolonged exchange of journalistic amenities. Dr. ROGERS' report is, however, so much more occupied with dealing with what he considers my errors, than in establishing his own case, that I feel sure that those who are at the pains of reading it, will confess that I could hardly do less than make as complete a reply as can be condensed into a single letter "to the Editor."

Yours &c., G. M. GILES, M.B. Lond., F.R.C.S. Eng.

Surgeon-Major, I. M. S.

SINGAPORE, 15th December 1897.

THE WRONGS OF MILITARY ASSISTANT SURGEONS. HOW THEY ARE TO BE RIGHTED.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I agree with all that "Truth" has written in your issue of 16th November 1897, but fail to see how the Director-General, I. M. S., is to blame. He may be and probably is, aware of many of the grievances of the Assistant Surgeon class, but I feel quite sure he is powerless, unaided to remove them. I cannot give satisfactory reasons for the statement I have made, and can only say it is my belief that had he the power to remove the grievances of Military Assistant Surgeons, they would not now exist. If the statements made regarding the excessive work of Military Assistant Surgeons are true, it should not be difficult to prove them, and once the tales of woe poured out in your columns are proved before a competent court to be true, the grievances they voice would almost certainly disappear. At present the Director-General has probably not received a single report from competent authority, i.e., a Military Court of Enquiry; or A. M. S. Officers, that Military Assistant Surgeons are over-worked. If Military Assistant Surgeons, who are in a position to do so, will carefully prepare a statement of a

day's "work done" in the ordinary course of hospital routine, noting each and everything done, and the time it takes to do; and if from these statements (the truth of which enquiry would prove, or disprove,) it is found that Military Assistant Surgeons are required to do more work than men can perform, the inference is obvious, the sick British soldier is neglected.

Prove to the Military Commander that the men under his control are neglected while in hospital, and a full and searching enquiry into the working of Station Hospitals follows as a matter of course. Till this is done, no results can be expected from letters to the *Indian Medical Record* or elsewhere, if plain-spoken expressions of opinion by the Editor, I. M. R., or letters exposing wrongs were of any use, they would have answered their purpose ere this. The Director-General can only act on reports received from officers of the A. M. S. It is the expressed opinion of some of these officers that the Assistant Surgeon in a Military Hospital has not too much to do, and that his grievances are imaginary, this being so, there is no sympathy for the Assistant Surgeon, he is looked upon as an imposter, and his statements disregarded. Either this class of A. M. S. Officer is right or he is wrong. If right, the Assistant Surgeon is an imposter and deserves kicking, if wrong, the A. M. S. Officer knows very little of the hospital for which he is responsible, or he is a deliberate liar,—that he is the latter I do not believe. It is easy for an A. M. S. Officer, even after some years in India, to know but little of the working of the hospital under his charge, everything is done for him, he signs his name to various papers, sees the morning sick, and goes home with the comfortable feeling that he has done his work and will no more that day be worried. If he is what is termed a good fellow, he appreciates the work done by his assistants, and, far as is possible in a Station Hospital, his subordinates are happy and content; for it takes but little to satisfy men accustomed from boyhood to scant courtesy and neglect. If he be of any of the following types, said sometimes to occur in the A. M. S. Tyrant, Bully, Shirker of work, or all combined, life in his hospital becomes a curse to the Assistant Surgeons employed in it. The junior Commissioned Officers do not apparently realise that they are responsible for anything beyond prescribing for the sick soldier; it never apparently strikes them when they complain of over-work with 80 or 100 patients to prescribe for that their Assistant Surgeons are doubly overworked, as they not only accompany them round their wards and write their prescriptions, but also compound, dispense, and serve out the medicines ordered; take temperatures, see to the bedding, clothing, diet, and extras of the patients,—in fact attend to the innumerable petty wants of 80 or 100 sick men. Yet it is the expressed opinion of some A. M. S. Officers that Assistant Surgeons are not over-worked. I believe that many gentlemen among the young officers of the A. M. S. have yet to learn that they have unconsciously lent themselves to a system of abuse, which, had they realised, they would have scorned. How can an officer of the A. M. S. know that his Assistant Surgeon is over-worked? The Assistant Surgeon dare not say he has too much to do, such a statement can be construed into a military crime against discipline; he dare not say that with so many duties to perform the sick soldier is necessarily neglected, military

Station, as witnessed in Station Hospitals here the way. He must just do his best; if the soldier suffers the Assistant Surgeon knows he is helpless to prevent it, and he further solves his conscience by saying his superior officer is responsible. The S. M. O., when of the tyrant class; never sees what work has been done, his object is to discover petty omissions, and to hold the threat of a bad confidential,—that curse of the service,—over a man for having neglected to have a soldier's boots brushed, or for having failed to see a cob-web on a skylight. The shirker of work adds to the burdens of his subordinates by elaborate rules all made with the object of minimising trouble to himself in the performance of his small share of work, i.e., seeing the morning sick. In some Station Hospitals a written statement of the case of each detained man must be made by the W. M. O. on duty for the information of the S. M. O. to enable him to prescribe for fresh sick patients without the trouble of questioning them (on occasions there are from 50 to 100 men detained). The Assistant Surgeon on duty, with all his other work to do, cannot in these cases give the result of his personal observation; he must question the patients, and write what they say, not what he has seen. Such statements answer no useful purpose, they simply add to one man's work, and diminish the work of another who has already very little to do, and who is too lazy to question the soldier about his illness. A skulk introduces the system into a Station Hospital, and it is perpetuated, because military discipline forbids remonstrance against any order. Military discipline requires unreasoning obedience, and applied to military matters is suitable, but the power military discipline gives when vested in quasi-military men, becomes as dangerous as an edged tool in the hands of a child.

In some Station Hospitals an Assistant Surgeon has from 100 to 150 sick under his care, and it is considered necessary to appoint two medical officers to prescribe for this number; this being true, there can be no doubt that there are too many Surgeons, and too few Assistant Surgeons for the work. The care of 80 sick soldiers necessitates at least two hours' work on the part of the Assistant Surgeon, to take temperatures, and see to the general condition of things (not excepting the polishing of boots, and the dusting of sky-lights), before the arrival of the Surgeon in charge of the ward. The first issue of medicine is also included in the work done before the Surgeon's arrival, the Assistant Surgeon then goes round with the Surgeon, and it is not too much to suppose that it takes two hours to see 80 cases of sickness among soldiers, if the work is conscientiously done; writing up bed-head tickets takes up half the time. When the Surgeon has finished, the Assistant has been four hours on his legs; the Surgeon has now finished for the day, and goes home to return again in the evening (?) to ask if anything is wanted. If a hard-working man with social instincts, he may go into the Surgeon's Office, and smoke a cigar, and write cases daily for half an hour, if not he arranges that with the help of his Assistant Surgeon, the cases are written in the ward. He finishes his work in 2½ hours. This is the ordinary routine of work of a junior A. M. S. Officer. [Compare this with the statement made by "Surgeon, Captain A. M. S." in the I. M. R. for 1st December 1897. Under exceptional circumstances I have seen an A. M. S. Officer work all day.] When finished with the Surgeon

the Assistant compounds and dispenses the medicines for 80 or 100 sick; one hour's work at least if carefully done, he arranges that dressings, bandages, &c., are properly applied, he serves out the fresh medicines ordered at the morning visit, and sees that the wine, &c., ordered for his patients reaches them, all this work takes at least another hour. Allowing that he started work at six o'clock by twelve o'clock he has done six hours' work, and night, one would suppose, he at liberty to rest, and have his breakfast; not so however he has to parade his discharged men and wait about the Hospital till the S. M. O. goes home. The S. M. O. usually in the winter comes after having had his breakfast, and is not particularly anxious about when he leaves, provided always he can return home for lunch. To prevent possible inconvenience to this august personage, men who have worked hard for six hours must hang about the office in case they are required to answer some question about men in their wards. By this time the second issue of medicine is due, and the Assistant Surgeon must either serve it out, or entrust the work to an A. H. N. corps coolie; if he does it himself he cannot go home till 2 o'clock. At four o'clock the third issue of medicine is due, and he must return to serve it out, take temperatures, and acquaint himself with the condition of fresh admissions and serious cases for the information of the Surgeon, who does not usually go round his wards, but expects his Assistant Surgeon to inform him of any serious case. This takes at least three hours to do. Thus far we have followed the Military Assistant Surgeon in the ordinary routine of work, when not on duty, and find he has eleven hours of work a day. We will take for granted that where military discipline reigns supreme, he did not delegate the second issue of medicines to a coolie, eleven hours' work excludes clerical work, which in every Station Hospital is exacted from the Assistant Surgeon employed in the wards; the amount varies, but clerical work (though forbidden by regulations) is exacted from all. Were Station Hospitals sufficiently equipped with appliances (thermometer, measure glasses, &c.) and menial servants, an Assistant Surgeon could, by working eleven hours a day, attend to 80 sick soldiers. Under the regulation in force, with the added terrors of a bad confidential report, the responsibility for everything begins and ends with the Assistant Surgeon. The A. H. N. Corps man, knowing the condition of things, wilfully or accidentally fails to carry out an order, and the Assistant Surgeon dare not report him. Should he be unwise enough to do so he is told "Why did not you see it done? You are responsible." Fragile articles, such as measure glasses and thermometers, if broken while in use, have to be paid for by the Assistant Surgeon. If he objects, military discipline, and the threat of a bad confidential soon bring him to his senses. With insubordinate and irresponsible menial servants, and insufficient appliances, the work cannot be done under 12 hours: add twenty or thirty sick to the number requiring attendance, and the work cannot be done, even if a man were able to work for 12 hours day after day in an Indian climate. When to the duties, already enumerated, are added those required from the ordinary W. M. O. the working of the Station Hospital system is proved faulty. If Military Assistant Surgeons are at any time required to attend to the wants of from

80 to 150 sick soldiers, the men under their care must be neglected, for no man can do the work expected daily from a Military Assistant Surgeon. With the facilities afforded them by the "Indian Medical Association," and the *Indian Medical Record*, it should be easy for Military Assistant Surgeons to prove these statements. If it is once proved that Military Assistant Surgeons are over-worked, and that the sick soldier suffers in consequence of their over-work, and that the highly paid Commissioned Medical Officer ordinarily does nothing towards the care of the sick beyond prescribing, and contents himself with issuing orders, which he should know cannot be satisfactorily carried out owing to there not being a sufficient number of Assistant Surgeons, a change of system must follow. The Editor, *Indian Medical Record*, may if he considers it necessary, call the attention of the Military authorities to this letter, and produce the writer as evidence; for obvious reasons I ask him not to divulge my name till Government has ordered an impartial enquiry by competent Military,—not Medical Officers.

Yours &c., M. A. S.

PERHAWAR, 9th December, 1897.

—:o:—

ARMY STATION HOSPITALS, HOW THEY ARE WORKED.

III.—DISCIPLINE.

TO THE EDITOR, "INDIAN MEDICAL RECORD"

SIR,—This is a subject that has to be approached with caution, because if there is one thing more than another that distresses the Army Medical Staff Officer, it is the discipline that obtains in Station Hospitals. The opinion among them is general that (1st) discipline is still a desideratum; (2nd) that the Assistant Surgeon class are, as a body unable to maintain it as it should be; (3rd) that the cause of this inability is mainly due to the circumstance that the British soldier is of too imperious a nature to be controlled by a body of men, who are for the most part of mixed descent and not the "regulation color." Let us, if we can, impartially examine these opinions and see how far they are the outcome of facts.

In the days of Regimental Hospitals complaints against breaches of discipline were of rare occurrence. Some will allege because then there was a Hospital Sergeant to maintain it; but any man, be he officer or subordinate, who has worked under both systems, will alone be best able to discuss the question thoroughly. In considering a case of breach of discipline, it is necessary first to know what the nature of the crime is. In Station Hospitals it is a crime for a man to spit on the floor, to smoke in bed, to smoke in the wards, to be in possession of money or other articles not obtained through an order of the medical officer; to go to the dinner-table minus his coat, to go downstairs or to the lavatory without his boots. It is a crime to be out of bed in an adjoining verandah after tattoo, never mind what the thermometer registers, &c. Now these restrictions are all salutary no doubt, but inasmuch as many of them demand an instantaneous change of habits, patients consider them vexatious, and evasion of them justifiable. The Hospital Sergeant of former years only took cognizance of crime—barrack-

room crime I may say. Except when clerical work kept him to his desk, he was not tied to the hospital; and, as a matter of fact, was never on the premises for the best part of twenty-four hours; so I think he may justly be discarded as a factor in the chief maintenance of discipline. Hospital crime was rare, because the hundred-and-one restrictions placed on the patient now did not exist. The Medical Warrant Officer remained then, as he does now when on orderly duty, all day on the hospital premises. Cleanliness and order were maintained in Regimental Hospitals by an adequate staff of servants, a few European orderlies—private soldiers with no authority—and, the word influence exercised on the soldier patient by the Hospital Staff of officers and subordinates to whom he was in most instances personally known. The "Doctor" worked in harmony with his assistant perhaps for years, and both were in touch with officers and men of the corps. But now all this is changed, and the cry goes up, for the blessings of discipline. We are provided with excellent rules if they could but be enforced; but where is the agency to enforce them. I say it in all seriousness that no single man, whether he be an Eurasian Assistant Surgeon or a full-blooded European Brigade-Surgeon-Lieutenant-Colonel, could by his mere presence in the hospital with multifarious duties to attend to, and be here there and everywhere, present the commission of each "crime" as I had enumerated above. And let me call attention to the fact that, it is in the perpetration of such misdemeanours only that discipline is lacking in Station Hospitals. Crime of a nature that would receive serious cognizance from a combatant officer is as rare to-day in our military hospitals as ever. If there is a change, it is for the better, thanks to the enlightened ruling enacted with a view to lighten the restrictions of a soldier's life. The fact is, that the unsatisfactory state of things in a Station Hospital is primarily due to the discontent of the Army Staff Officer, who in nine cases out of ten brings only a half-heartedness to his work. In deploring the absence of that discipline that he so much desires to see established, medical officers are themselves much to blame in their lack of co-operation in striving to maintain it. Any circumstance that brings the Army Medical Staff Officer in relation to his brother combatant officer that is not of a professional nature, is sedulously avoided by the former, from the sheer sensitiveness engendered in his nature by his anomalous status in the army; hence the infraction of rules in hospital by patients when detected by medical officers themselves are noticed, as matters that call for censure or reproof, not of the delinquent, mind you, but of the Assistant Surgeon. Patients are exonerated from responsibility; even Non-Commissioned Officers in hospital, who, according to Army Regulations are responsible for the maintenance of discipline, in hospital as much as they are in the barrack-room, are never questioned. The Army Medical Staff Officer shirks the responsibility himself of taking action called for, because it may involve his presence in the regimental orderly room, or a correspondence with combatant officers. The Assistant Surgeon is expected to do the dirty work, and all of it. TOMMY ATKINS, with the eye of a soldier, sees this; he knows too that the man of whom so much is expected, cannot find time for much detective work, and

has been a result of the exaggerated effect of ignoring medical rules. The Assistant Surgeon (not from fear, but from a worthy motive mind) abstains from punishment, when infringement of rules is not perpetrated by a deliberate act of authority.

The desire to be popular with the soldier exhibited mostly by junior medical officers, would be admirable, if it were not, as it is too often, purchased at the sacrifice of duty, or the pecuniary interests of the State. I have referred to the ignoring of individual responsibility of patients for the maintenance of discipline, order, cleanliness, &c., as if they were children, though outside a hospital nobody thinks of indulging T. A. to that extent. Examine the diet sheets of our Military Hospitals, and you will find "extras" lavishly prescribed, not because the case absolutely needed them, but because they were asked for, or there was "no harm" in prescribing them. This does not refer to "supplementary extras," because ordering those entails an entry in the case book, and a medical officer with forty or more patients in his charge hesitates to fill his case book with entries of trivial cases that have no particular interest. A volume could be written, giving instances showing the utter disregard medical officers evince touching the individual responsibilities of patients, but one will suffice. It is an extreme case, but its very extremity exemplifies how far matters may be pushed. An insane patient with four orderlies over him, shot himself dead with a rifle taken from the guard. The Warrant Officer on orderly duty was considered culpable and arrested. It is needless to say he was acquitted by combatant officers with a knowledge of something higher than hospital discipline. Here the patient was not responsible, but the orderlies and the guard were, but this very circumstance renders the charge brought against the Warrant Officer and the action taken against him (he was two months under arrest) one of a nature to make us ask, under what manner of discipline are our hospitals ruled.

The Officer of the Army Medical Staff, as we all know, is a man with a grievance, but in the strenuous endeavours he is making to have that grievance redressed, I hardly think it judicious of him to make present conditions worse than they might be. He is not content with Station Hospitals as at present organised; he wants men of the Medical Staff Corps for subordinates. I see nothing unreasonable in this: he is used to such subordinates everywhere but in India; and it occurs to many of us in both Commissioned and Warrant ranks that the question of re-organising our Station Hospitals will have to be faced before long, if we do not mean to wait for total collapse. We are on the brink of it now. If in the military organisation of India, as it stands at present, the services of the Subordinate Medical Department can be dispensed with, if it would be a measure of economy to wipe it off the face of the Army List and bring in the Medical Staff Corps—why not do this? Discipline would be better maintained, because we should have then a staff of orderlies and Non-commissioned Officers instead of one Warrant Officer required to be ubiquitous, and there would always be an duly Commissioned Medical Officer on the premises of the hospital. It will be better than the present make-believe state of affairs: there will be no expensive superfluous staff.

If, added to this, medical officers be furnished with the power to punish patients for slightest infractions, I think we will have advanced one step further in securing a better order of things.

In concluding this letter the objection occurs to me that, in the large Civil Hospitals of the Presidency Towns, where rules for the maintenance of cleanliness and order—I won't say discipline—are as stringent if not more so than those regulating Station Hospitals, matters progress very satisfactorily. And this result is attained by means of all shades of color. How? The nurse is always present in her ward, delinquents are brought by her to the notice of the physician or surgeon and punishment awarded: it is generally dispensed from hospital. Unfortunately this can't be done with T. A. woe's the pity.

Yours &c., SURENDRA INDRA.

GRIEVANCES OF CIVIL HOSPITAL ASSISTANTS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—It is a patent fact that the grievances of that useful class of Subordinate Medical Officers—the so-called "Hospital Assistants"—a designation which is at least a misnomer—are manifold and require urgent and generous consideration at the hands of the Government. Several important editorials, comments, &c., about these have, from time to time, appeared in the columns of our valuable journal, the 'Record'; and the "Indian Medical Association" was also good enough to send in a memorial to the Supreme Government on our behalf as regards some reasonable improvement in our pay, status, &c. It is a long time since we were asked to wait for a reply from Government which, it was supposed, would be an encouraging one, but far from it, during this period of patient and anxious expectation several of our brother Hospital Assistants have carried their hopes (of seeing better and happier days) to the grave. It is time enough that we waited, and we do not know what good, if any, will come by our waiting "ad infinitum"; for hope deferred maketh the heart sick. I beg to request therefore that the Indian Medical Association may be so good as to leave no stone unturned as regards the betterment of the prospects of the poor over-worked and under-paid Hospital Assistants by sending a gentle reminder to the Government. The hardships and difficulties to which these poor unfortunates are subject are more to be imagined than described. The zealous and earnest way in which they work under the most adverse circumstances, as in famine and plague, is a sufficient indication of how loyal and obedient they are. They are always to the front in epidemics, e.g., cholera, plague, &c. They are ever ready to do their duty even at the risk of their lives.

It may not be out of place for me to suggest that all the Editorials, Comments, Correspondence columns, &c., of the *Indian Medical Record* touching on our grievances may be collected from 1st January 1890 up to date, and printed in a pamphlet form at the Record Press. Such a

* While writing this, it has been suggested to me that, instead of an economy being effected by the removal of the surplus, it might be better to have, because the responsibility of the A. M. S. Officer would be very much increased: when there is just after now, there would need to be two with the men of the Medical Staff Corps as subordinates.

pamphlet, besides being invaluable to each and every Hospital Assistant, might advantageously be sent up to the authorities when redress of the grievances is requested again; and all the Commissioned Officers of the I. M. S., who are in sympathy with us, would be glad to receive a copy of it and do their utmost to ameliorate the hard lot and wretched plight of their poor and deserving, though unfortunate, subordinates. But then a question arises as to the source of the funds from which the cost of its publication and circulation is to be met. This is not a hard nut to crack, because the cost of the undertaking will not probably exceed five or six hundred rupees. There are over a thousand Hospital Assistants in India, and that means something like half a rupee or so will have to be contributed by each which, I fervently hope, will be acceptable to all concerned for their own amelioration; even the most selfish, if any, among us, will not, I think, grudge the payment of this amount. The publication of a pamphlet on the lines indicated is a desideratum, and the time for such a publication need no longer be delayed. All Hospital Assistants, whether subscribers to the *Record* or not, will, it is hoped, kindly take this as an earnest appeal for co-operation and mutual help. As to my identity, dear Editor, I herewith enclose my card and wish you and your numerous readers a happy and prosperous new year.

Yours &c., "MULUM IN PARVO."

MADRAS, 23rd December 1897.

—:O:—

MORE ADVERTISING QUACKS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—The following advertisement finds a prominent position in *The Morning Post* :—

MEDICAL OPINIONS.

Upon Blindness, Deafness, &c.,

All Diseases

OF THE

Eye, Ear, Nose, Throat, &c.

All symptoms which are treated on the Latest and most Modern System of Practice.

DR. ENGLER.

Oculist, Aurist, and Specialist, has arrived from Europe and has paid his first professional visit to

DELHI,

And may be consulted daily at the Northbrook Hotel, From 8 to 12 A.M., and from 1 to 5 P.M.

Here are quoted a batch of "puffs" and then the advertiser adds—

"Dr. ENGLER will not visit the Mofussil Stations, except by special arrangements and for a short period."

Surely men like this need[ed] showing up, and the penalties of a Medical Act are called for in just such cases.

Yours &c., M. D.

—:O:—

RESEARCH IN INDIGENOUS DRUGS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Will you kindly give me the following information and oblige. Do you know of any laboratory or institution for the investigation of the medical properties,

physiological action, &c., of the native drugs of India in Calcutta or any other part of India. If there is such an institution, can you give me some information about it. Is there any institution where medical books in Sanskrit and other Oriental languages are translated and studied? Or if you know of any medical men who specially study the subject?

Yours &c., RUSTOMJI ADENJI.

Medical Officer, Rajkot State.

RAJKOT, 22nd December 1897.

Book Review & Medical Trade Notices.

A HAND-BOOK OF SURFACE ANATOMY AND LANDMARKS.

By BERTRAM C. A. WINDLE D. SC., M.D., M.A. Dublin.

And T. MANNERS SMITH, M.A. Camb., M.R.C.S.

(Publisher: H. K. LEWIS, 136 Gower Street, London, W.C. Second Edition. Price 3s 6d.)

THIS handy little book of 143 pages is one of the most useful helps that the medical student or the practitioner can possess to aid him in a practical and intelligent understanding of regional anatomy, as well as clinical surgery and clinical medicine. It is perfectly illustrated, and cleverly designed in all the arrangement of its sections and the literary descriptions of the same. We strongly commend this booklet to the medical profession of India.

VINOLIA PRODUCTS.

(BLONDEAU ET CIE, MALDEN-CRESCENT LONDON, N.W.)

ACCORDING to our examination the Vinolia preparations consisting mainly of articles for toilette use afford distinct evidence of the endeavour of these manufactures to use only innocent yet effective ingredients. This is the only point which interests us in regard to such preparations. We have not found a single injurious constituent in any one of the new preparations recently submitted to us. An enormous advance has been made in the preparation of soaps, hair-washes, powders, shaving materials, &c., during the last twenty years, a fact which has contributed not a little to the comforts and sanitary conditions of modern life. Of new preparations recently submitted to us we may mention three soaps respectively entitled "buttermilk," "lilac," and "heliotrope," each of which carries its own distinctive yet delicate scent. They contain nothing but bland soap and are free from any resinous matters or trace of free alkali. Vinolia violet powder is very finely divided and in addition to this desirable condition is a harmless antiseptic. Another preparation worthy of notice is the Vinolia dry hair wash. It is of course a spirituous fluid which yields on evaporation, a delicate lather but without stickiness. It is satisfactory to find that articles of the quality "described may be obtained at quite a moderate figure.

SOLOIDS FOR USE IN GYNÆCOLOGY.

(BURROUGHS, WELLCOME AND CO., SNOW HILL BUILDINGS, E. C.)

The following formulae have recently been adopted by Messrs. Burroughs, Wellcome and Co., in solid form. 1.

Sodium bichlorate compound, each solid containing 20 grains of sodium bichlorate and 10 minims of tincture of opium. 2. Alum compound, each solid containing 15 grains of zinc sulphate and 15 grains of alum. 3. Zinc and tannin compound, each solid containing 5 grains of sulphate of zinc, 10 grains of lead acetate, 2 grains of extract of opium, and 1 grain of tannin. In this last formula obviously the zinc sulphate will, when the solid is placed in water react with the lead acetate to form acetate of zinc in solution and a precipitate of sulphate of lead. The resulting zinc acetate would then yield a zinc tannin compound. The object of these solids is to enable the practitioner to prepare solutions for irrigations in gynaecological practices.

Government Medical Gazettes.

GOVERNMENT OF INDIA.

The services of Surgn.-Capt. W. H. Gray and Surgn.-Capt. A. G. Hendley are replaced temply. at the disposal of the Mily. Dept. from the dates on which they respectively made over charge of their duties in the Genl. Prov.

First class Hosp. Asst. Pirbhoo Lal, Tonk Raj Dispy., was pensioned from 18th May 1897.

The following transfers have been made in the Estab. of Civil Hosp. Assts. in Rajputana :—

Mirza Mahomed Beg, from Bikanir Raj Service to Native States Reserve List. 15th Aug. 1897.

Rahmatall, II, from Native States Reserve List to Kotah Raj Service, 1st July 1897.

Waizul Huq, from Marwar Raj Service to Kotah Raj Service, 9th July, 1897.

Sadasaivrao Gokhale Ramchander, from Native States Reserve List to Marwar Raj Service, 30th July 1897.

Zahur Peer, from Native States Reserve List to Marwar Raj Service, 25th July 1897.

Insar Pershad Chakravarty, from Govt. Reserve List to Marwar Raj Service, 1st Aug. 1897.

Hosp. Assts. Ahmad Khan and Sital Pershad were apptd. 3rd class Hosp Assts. and placed on the Native States Reserve List from 18th Sept. and 1st Oct. 1897.

Hosp. Asst. Habibur Rahman, Mandana Dispy., in Kotah, died 9th March 1897.

The following Hosp. Assts. availed themselves of privilege leave :—

Polo Ram, Bhagwan Dass Hosp., Bikanir, from 18th July to 18th Aug. 1897.

Shiveshanker Dayashanker, Northern India Salt Revenue Dispy., Pachbadra, from 2nd Sept. to 15th Sept. 1897.

Jowala Pershad, Western Rajputana States Resy. Hosp., from 18th Sept. to 25th Oct. 1897.

Lukhpat Rai, Sirohi Dispy., from 8th Sept. to 25th Oct. 1897.

Madan Lal, Deolia Dispy., in Ajmere, from 4th Sept. to 3rd Oct. 1897.

Hosp. Asst. Mahomed Zahurul Huq, Jaypore Raj Service, privilege leave for twenty days from 17th Dec. 1896.

Hosp. Asst. Raja Ram Singh, Lanadowne Hosp., Oodeypore, one month's privilege leave from 4th April 1897.

BENGAL GOVERNMENT.

Asst. Surgn. R. F. Knight, Asst. to the Supdt. Med. Coll. Hosp., to act as Apothecary to that institution, from 4th Oct. 1897.

Asst. Surgn. Amulya Chandra Champati, Krishnagar Charitable Dispy., held med. charge of the Civil Station of Nadia from 30th Aug. to 31st Oct. 1897.

Asst. Surgn. Kheroda Chandra Chowdhuri, Krishnagar Charitable Dispy., held med. charge Civil Station of Nadia from 1st to 3rd Nov. 1897.

Asst. Surgn. Amulya Chandra Champati, Krishnagar Charitable Dispy., to have med. charge Civil Station of Nadia, from 2nd Nov. 1897.

Asst. Surgn. C. A. R. Haegert to be Inspg. Med. Officer, Malwa, on the Bengal and N.W. Ry.

Surgn.-Major. F. A. Rogers to be Inspg. Med. Officer Chakradharpur, on Bengal Nagpur Ry.

Asst. Surgn. C. R. W. Brancroft, Presy. Genl. Hosp., Calcutta, to act as Asst. to Surgn. Supdt., Presy. Genl. Hosp., until further orders.

The services of Asst. Surgn. F. Victor, Offg. Asst. to the Surgn. Supdt. Presy. Genl. Hosp., Calcutta, are replaced temply. at the disposal of the Govt. of India, Home Dept.

Asst. Surgn. Khagendra Nath Sen, Bettiah sub-div. and dispy., leave for one month and 25 days, from the date he avails himself of it.

Babu Dattari Dass, clerk attached to the office of the Civil Surgn. of Cuttack, has been dismissed from the service of Govt.

Asst. Surgn. Suresh Chandra Banerjee is re-apptd. as Asst. Supdt. of Emigration, Ranigunge and Amnool, from 2nd Dec. 1897.

Asst. Surgn. Suresh Chandra Banerjee did supy. duty Ranigunge Dispy., from 31st Aug. to 21st Sept. 1897, and at the Presy. Genl. Hosp., from 22nd Sept. to 24th Nov. 1897.

PUNJAB GOVERNMENT.

Hosp. Asst. Kahan Singh reported himself to the Civil Surgn., Rawalpindi, for genl. duty, 18th Dec. 1897.

Hosp. Asst. Lal Singh, from Jail Hosp., Ferozepore, to Murres Dispy., Rawalpindi dist., 27th Nov. 1897.

Hosp. Asst. Ghasia Mal Horra, from the latter to the former institution, 7th Dec. 1897.

Hosp. Asst. Usman Ghani, Police Hosp., Ferozepore, held charge, Jail Hosp., from 15th Nov. to 7th Dec. 1897.

The services of Hosp. Assts. Labha Mal and Mathra Das being no longer required by the Govt. Centl. Prov. they reported their arrival at the office of the Inspg.-Genl. of Civil Hosps., Punjab, Lahore, 14th Dec. 1897, and were apptd. to do genl. duty, Mayo Hosp., Lahore.

Asst. Surgn. Brij Lal, Ludhiana Civil Hosp., was placed on special plague duty at Kalka, from 28th Nov. to 6th Dec. 1897.

Hosp. Asst. T. Franklin, doing genl. duty at Delhi, for special plague duty at Wazirabad, Gujranwala dist., from 8th Dec. 1897.

Hosp. Asst. Husain Shah Believing Hosp. Asst. N.W. Ry., was placed on special plague duty at Khan Khanan, Jullundur dist., 14th Dec. 1897.

Hosp. Asst. Gurmukh Singh was apptd. on special plague duty at Khan Khanan, Jullundur dist., from 11th Dec. 1897.

Hosp. Asst. Amir-ud-din reported himself to the Civil Surgn., Jullundur, for genl. duty, 16th Dec. 1897.

Hosp. Asst. Bahadur Shah, Gurdaspur Dispy., was apptd. as a tempy. measure, to the Batala Dispy., from 10th Dec. 1897.

Hosp. Asst. Sunder Singh, doing genl. duty at Umballa, to Khanpur for special plague duty, 8th Dec. 1897.

Hosp. Asst. Bahadur Shah doing genl. duty at Lahore, to the Gurdaspur Civil Hosp., 3rd Dec. 1897.

Hosp. Asst. Bahadur Shah did genl. duty at Gurdaspur from the 30th Nov. 1897, and from 1st and 2nd Dec. 1897.

CENTRAL PROVINCES GOVERNMENT.

The services of Hosp. Asst. Pratab Singh and Yado Rao are placed at the disposal of the Direc.-Genl. I. M. S., for plague duty at Ajmere.

Hosp. Asst. Govind Deo Rao is posted to the Baloda Branch Dispy., Raipur dist.

Hosp. Asst. Govind Deo Rao Baloda Branch Dispy., Raipur dist., to the med. charge Baloda Poor-house.

Hosp. Asst. Ashtaq Husain Jail and Police Hosps., Saugor, three months' privilege leave from 15th Nov. 1897.

Hosp. Asst. Lachman Pershad to the Jail and Police Hosps., Saugor.

Hosp. Asst. Muhammad Umar Khan to do duty under Civil Surgn., Narsinghpur.

Hosp. Asst. Muhammad Umar Khan doing duty under Civil Surgn. of Narsinghpur, to the Jail and Police Hosps., Narsinghpur.

Hosp. Asst. Muhammad Hanif to do duty under Civil Surgn. of Nagpur.

Hosp. Asst. Ramasahi, on famine duty, Bhandara dist., to Nagpur for plague duty.

Hosp. Asst. Ashutosh Chatterji to do duty under Civil Surgn. of Nagpur.

Hosp. Asst. Baliram to do duty under Civil Surgn. of Nagpur.

Hosp. Asst. Chandra Shekara Ray assumed charge Civil Hosp. Fak, Pakokku dist., 14th Nov. 1897.

Hosp. Asst. Josiah Maslamoney assumed charge at Jail Hosp. Swagun, 26th Nov. 1897.

Hosp. Asst. Maung Aung Pru assumed charge Police Hosp., Pakokku, 9th Nov. 1897.

Hosp. Asst. Maung Aung Tun assumed charge Jail Hosp., Pakokku, 9th Nov. 1897.

Hosp. Asst. B. B. Churkerbutty assumed charge Police Hosp. Pika, Magung, 27th Nov. 1897.

Hosp. Asst. Amrita Lal Gaba relinquished charge of duties with Mr. P. W. Dept. at Kaler, Southern Shan States, 26th Nov. 1897.

Hosp. Asst. Ramakrishna Jagannath Das, is reduced to the grade of Second Med. Pupil, by the orders of the Chief Commr., from 19th Sept. 1897.

Hosp. Asst. Muhammed Siddiq, and passed Medl. Prpl. Muridun.

Hosp. Asst. Muhammed Haidk, 7th Dec. 1897.

Bali Ram, 6th Dec., 1897.

Achutash Chatterji, 7th Dec. 1897.

Girdhari Lal, 10th Dec. 1897.

The following Med. Sub. to do duty under Civil Surgn. of Subinipore:—

Hosp. Asst. Hari Gopal Chatterji, Sedar Dispy., Rao Bareil, privilege leave for three months from the date of making over charge.

Asst. Surgn. Sri Ram, on Reserve duty, Lucknow, to the off. charge Sedar Dispy., Rao Bareil.

Asst. Surgn. Rishambhai Sahai, on special duty at Hardwar, has been on plague duty at that station from 27th March 1897 and is still on that duty.

Asst. Surgn. Prakesh Chandra Mukerji, Sedar Dispy., Aligarh, held civil med. charge of the Aligarh dist. on the 7th and 8th March 1897.

Asst. Surgn. Balig Ram, Sedar Dispy., Jhansi, held civil med. charge of the Jhansi dist. from the 18th to 22nd Aug. 1896.

BURMA GOVERNMENT.

Hosp. Asst. Karim Khan assumed charge Ry. Dispy., Nyanagchidank, Toungoo dist., 30th Nov. 1897.

Hosp. Asst. Khaburuddin assumed charge of duties, Jail Hosp., Rangoon 23rd Nov. 1897.

Hosp. Asst. Khaburuddin to hold charge Contagious Disease Hosp., Rangoon, from 23rd Nov. 1897.

Hosp. Asst. Khaburuddin assumed, charge Police Hosp. Rangoon, 23rd Nov. 1897.

Hosp. Asst. C. A. Chinaswamy Pillay, leave for one year, 9th 1897.

Hosp. Asst. Tijamal Humain assumed charge Police Hosp., Bhamo, 20th Nov. 1897.

Hosp. Asst. Wasir Singh assumed charge Civil Hosp., Mingin, Upper Chinlwin dist.

Hosp. Asst. Wasir Singh assumed charge Police Hosp., Mingin, Upper Chinlwin dist., 10th Aug. 1897.

Hosp. Asst. M. Parumal Pillay relinquished charge Famine Relief Works Hosp., Taungtha, Myingyan dist., 30th Nov. 1897.

Hosp. Asst. Chandra Shekara Ray assumed charge Civil Hosp. Pauk, Pakokku dist., 14th Nov. 1897.

Hosp. Asst. Josiah Maslamoney assumed charge at Jail Hosp. Swagun, 26th Nov. 1897.

Hosp. Asst. Maung Aung Pru assumed charge Police Hosp., Pakokku, 9th Nov. 1897.

Hosp. Asst. Maung Aung Tun assumed charge Jail Hosp., Pakokku, 9th Nov. 1897.

Hosp. Asst. B. B. Churkerbutty assumed charge Police Hosp. Pika, Magung, 27th Nov. 1897.

Hosp. Asst. Amrita Lal Gaba relinquished charge of duties with Mr. P. W. Dept. at Kaler, Southern Shan States, 26th Nov. 1897.

G. O. C.

Native Mily. Pupil Khushhal Chandra, passed exam. is admitted into the service as a Surgeon, 20th Oct. 1897.

To be 1st class Asst. Surgn.—Asst. Surgn. W. A. Boucher, from 20th Oct. 1897.

Hosp. Asst. Ismail Khan to be 2nd class Asst. Surgn., 24th April 1897.

Surgn.-Major H. Hendley, Joint Civil Surgn. of Chitab, to the med. charge of the Army Head-Quarters Staff and estate, remaining at Simla during the winter, from 1st Nov. 1897.

ASSAM GOVERNMENT.

Hosp. Asst. Mahendra Chandra Chakravarti, on being relieved of the med. charge of the Sairang Mily. Police outpost in the North Lushai Hills, 1st Oct. 1897, was employed as a supy. in that dist. from 2nd to 21st Oct. 1897.

DOMESTIC OCCURRENCES.

The charge for inserting a Domestic Occurrence is Rs. 1 for subscribers and Rs. 2 for non-subscribers, which should be forwarded in stamps with the announcement.

BIRTH.

SEWLE.—On the 17th Dec. 1897, at Kasauli, the wife of Surgn.-Maj. J. Semple, A. M. S., of a daughter.

MARRIAGES.

RIORDON.—EVANS.—On the 12th Dec, at Fort Chapel, Bombay, by the Very Rev. J. House, B.J., John Riordon, Surgeon-Major, Army Medical Staff, to Gertrude, daughter of the late Mr. H. W. Evans and Mrs. Evans, Naville House, Newport, Monmouthshire.

BOWSON.—GLORDON.—On the 20th Dec., at Bombay, by the Rev. E. M. Gray, M.A., assisted by the Rev. Frank Ashcroft, M.A., Robert George Bowson, M.A., M.B., C.M., Rajpootana, son of the Rev. George Bowson D.D., Perth, Scotland, to Helene Louise, fourth daughter of the Rev. Charles Auguste Glordon, M.A., Vesey, Switzerland.

NOTICES TO CORRESPONDENTS.

Durrant's Press Cuttings.—This Company is a London one and its office is at 57, Holborn Viaduct E.C., It provides news cuttings suitable to every kind of journal or newspaper for a small annual fee.

W. B. G. (Karachi).—Go in for the L.R.C.P. & S. Ireland. When you are ready we shall be glad to help you in any way we can. Your certificates will be fully accepted. You will have to pass in all the professional subjects. Six months' study ought to see you through safely.

Medical Advertising.—We continue to receive numerous letters advertising medical men in Calcutta. We have warned those who are doing so, and we shall shortly give the advertisements which are being published in the daily papers of Calcutta, full publicity in this journal.

K. K. R. C. (Benares).—Your paper is still crowded out as it needs much "editing," and our time is very fully taken up at present.

H. K. S. (Raigarh).—The above remarks apply also to your paper.

D. L. B. (Peshawar).—Your suggestion about the "war reserve" is a very good one, and will be acted on.

Senior Assistant Surgeon.—It is quite possible the Government may confer the rank of Hony. Surgeon Lieutenant-Colonel on the Surgeon-Majors of the Warrent Medical Services on their retirement. One of them is, we hear, to be honored with a C. I. E.

A. P. (Hyderabad).—The conditions for the Fellowship must be duly fulfilled. We would advise you to address Dr. EDWARD LAWARE. You have excellent papers and he will recommend you to Edinburgh.

G. L. (Khart).—There are numerous persons in Darjeeling who, private persons keep hospitals, but none that we know of where persons of importance would be treated. An advertisement in the Record would settle this question.

system, and *panophthalmitis* are accidents which occasionally happen, provided the rupture occur with great violence. Perforation in some cases is preceded by the condition variously known as *keratocele*, *descometosis* or *hernia* of the cornea. This occurs when the suppurative process has gone so far as to reach the extremely resistant membrane of Descemet, which now forms the floor of the ulcer. In consequence of the vis-a-tergo supplied by the intra-ocular pressure, the membrane is pushed forwards without rupturing, in the form of a small transparent vesicle, which in many cases is large enough to protrude above the level of the rest of the cornea. Should this hernia of Descemet's membrane not give way eventually, so as to produce an actual perforation, it persists as a smooth, transparent vesicle surrounded by a hazy cicatricial ring formed by the gradual healing of the ulcer around the hernia.

After the first outrush of the aqueous on the occurrence of a perforation, its further escape is prevented by mechanical closure of the rent. This is effected by the apposition of the iris or of the crystalline lens. If the perforation is situated in front of the iris and is of small size, it is closed by the simple application of the iris to its posterior aspect, and in a short time the anterior chamber is re-established by fresh accumulation of the aqueous. The iris is, at the same time, restored to its original position, in some cases, however, the restoration does not take place, and a permanent adhesion between the iris and cornea results, forming what is known as an *anterior synchia*. If the perforation is larger, it is occluded by an iritic plug; this may involve only a small portion of the iris (*partial prolapse or hernia*) or the whole of it (*total prolapse or hernia*), as in those cases in which almost the entire cornea is destroyed by the suppurative process. In these cases the prolapsed iris cannot become disengaged, as it becomes firmly agglutinated to the margins of the corneal gap, and becoming covered over with a plastic exudate forms the basis of the cicatricial tissue. This adhesion of the iris to the corneal cicatrix (*anterior synchia*) necessarily leads to distortion of the pupil. The extent of the distortion, however, depends in a great measure upon the situation of the perforation and the portion of the iris engaged in forming the plug. The anterior chamber in all cases is irregular in form; it may be very shallow or be even absent.

During the healing of a perforating ulcer of the cornea with a comparatively large prolapse of the iris, it generally happens that by the contraction of the cicatricial tissue, which is formed over the protruding iris, the convex mass is flattened out, and the resulting *leucoma adhaerens* is perfectly flat. When, however, the cicatricial tissue is not strong enough to cause flattening of the iritic projection or to withstand the distending influence of the aqueous, the cicatrix, instead of being flat, is ectatic or *staphylomatous*. In the case of a total prolapse of the iris, the *leucoma* or *staphyloma* is necessarily total (*staphyloma corneae totale*).

When the perforation is central, that is situated in front of the pupil, its closure is effected by the gradual

formation of a thin cicatricial membrane within the margins of the opening; the iris meanwhile keeping in apposition to the opening from behind. In a few comparatively rare cases, in consequence of the mechanical closure of the perforation not being accomplished, or from repeated rupturing of the closing membrane, the corneal opening remains permanently open, and a *stetula* is produced. The aqueous keeps continually oozing out; the cornea flattens out (*phthisis cornea*), and the eye-ball becomes soft (*phthisis bulbi*) and finally atrophies. One of the results of a central perforation of the cornea is the development of an *anterior capsular cataract*. This arises from a deposit of plastic lymph on the capsule during the temporary contact of the lens with the posterior surface of the opening; it is especially observed after *ophthalmia neonatorum* (VON ARLT).

It is important to bear in mind that the occurrence of perforation is by no means an altogether unfavorable event, so far as its effects upon the course of the ulcer are concerned. In many cases, after the occurrence of the perforation, the symptoms of irritation, pain, photophobia and blepharospasm subside to a marked extent, and the ulcer itself begins to show signs of healing. This is probably due to release of the cornea from intra-ocular pressure (on account of the escape of the aqueous) and the consequent improvement which occurs in its nutrition from freer circulation.

To sum up, ulcerative keratitis may have one of the following terminations, complete recovery or *restitutio ad integrum*, without any opacity; (2) permanent cicatricial opacity; (3) *keratocele*; (4) perforation with its sequelae.

Aetiology—The causes which lead to ulceration of the cornea, whether primary or secondary, are precisely the same as those which give rise to abscesses. These have already been mentioned. In addition to them, the following may be cited as etiological factors standing in special relation to ulcers—

1. Defective closure of the lids as in keratitis—lagophthalmos.
2. Trophic disturbance of the cornea from paralysis of the trigeminus, as in keratitis neuroparalytica.
3. Constitutional impairment of nutrition in infants as in *keratomalacia*.
4. Absolute glaucoma.
5. Atheromatous degeneration of old corneal opacities.
6. Deliquescence of corneal abscesses.

In by far the large majority of cases, corneal ulcers occur in consequence of conjunctivitis; and so far as we in the Punjab are concerned, chiefly in consequence of trachomatous conjunctivitis. In the following table will be found the principal features of ulcers occurring secondarily

by the most important types of conjunctival inflammation which prevail in the country.

Conjunctivitis.	Situation.	Character.
1. Acute catarrhal conjunctivitis.	Margin of cornea and concentric with it.	Chiefly crescent-shaped; occur specially in elderly persons, and tend to increase in extent rather than in depth. Size small.
2. Acute blepharocconjunctivitis.	Sometimes at the centre. Sometimes at the margin; oftenest in the lower half of the cornea.	Occur during the height as well as during the regressive period of the disease. They spread rapidly both in diameter and in depth, and often end in complete (a marginal zone, however, is left intact) destruction of the cornea, or even in panophthalmitis.
3. Trachomatous conjunctivitis.	On any part of the cornea.	These ulcers are small, round or irregular by coalescence. They occur chiefly when pannus is present, and are the results of ulcerative breakdown of the infiltration at the margins or in the substance of the pannus. In many cases a single comparatively large ulcer is developed at the centre of the cornea, without any accompanying symptoms of irritation. It is a clean ulcer and heals incompletely and slowly.
4. Conjunctivitis lymphatica.	Marginal.	Small, superficial ulcers occurring singly or in groups, occur sometimes partly on the cornea and partly on the limbus. Heal easily. In <i>keratitis fascicularis</i> the ulcer carries a leash of blood vessels from the limbus, it never causes perforation of the cornea.

THE SANITARY CARE OF THE SOLDIER BY HIS OFFICER.*

By SURGEON-COLONEL G. J. H. EVATT, M.D., A. M. S.
(Continued from page 100, Vol. XIV.)

13 *Sanitary Inspections.*—I say, then, that those Medical Officers who are detailed for the sanitary care of regiments or batteries are doing those sanitary inspections frequently during the week. Thus on one day of the week they would go and inspect the barrack buildings and see them thoroughly, and I always find in any garrisons where I have been in charge as Medical Officer that it is not possible for any Medical Officer to do his sanitary duty properly by the regiment if he endeavours to carry out inspections of men and barracks on one day; because if he stops for a moment to look at anything that is defective in the sanitary state of the barracks he is sure to be keeping the men in a distant part of the barracks waiting for him and keeping them away from some

important duty. I repeat from long experience that it is not possible for any Medical Officer to make those inspections of men and barracks at the same time and on a single day.

14. The officer then inspects the barracks and he inspects the men. Now, many of the younger Medical Officers have complained, and are complaining, about the difficulty that they experience in carrying out these inspections. The other day I saw a letter in a military paper from a Medical Officer proposing that all these inspections should be abolished, that it was impossible to carry them out, and that they were a perfect farce. On the very day that letter appeared in the paper, on the parade of this very garrison one man was sent off parade sick with scarlet fever, out of the West River Range; another man was sent off sick with a disease like scarlet fever; and I myself on another inspection sent a man to hospital with jaundice. Now, why are the Medical Officers wishing to get rid of these inspections, for they are really a most important matter? It is because it is difficult for them to get proper parades of the men. They go into the barracks and they find it difficult to know to whom they should look; a parade is formed up for them in a scratch way and is often a feeble and farcical affair. I am not speaking of Woolwich particularly, but over and over again I have had to write to C. O.'s and point out that while the number of men in a corps or garrison is strong, the number on parades given to us are very weak.

15. In the same way in going about on the sanitary inspection of the barracks one does not know to whom to look to go round with one. I say to a Medical Officer, "You are posted to the sanitary care of such a regiment. I beg you to go down and leave your card at the orderly-room. I specially want you to know the Commanding Officer socially and personally," because unless you are able to approach him socially and personally you know when letter writing begins efficiency constantly ends, and it is essentially necessary that there should be the most free and complete intercourse between the two. But if we find this great difficulty exists in the first instance in getting our sanitary officers themselves taken round the barracks by some one who is responsible and who knows the barracks, and secondly in getting a good health inspection parade of men, the whole thing degenerates into a farce, and every soldier undervalues it. "Let us, I say, most earnestly come to some definite conclusion one way or the other on this sanitary routine; either let us do the thing well or let it be abolished," because to-day, in the year 1894, the question of half-and-half measures and compromise is coming to an end in everything, and we in the medical service want to know how our duties stand, and what they are, and we desire to do them if we are really responsible.

16. In a certain station abroad that I have got in my eye, I went to the Commanding Officer of a regiment in the garrison and I said to him, as the senior Medical Officer of the station, "It is my interest and yours that we should both work together. I will give you an officer who will make your regimental inspections, but I beg you to give him a responsible officer to go round with him." I said that, and I say still, that I do not consider that the officers who fill the post of

*A Lecture delivered at the Royal Artillery Institution, Woolwich, and sent to the Editor by the author.

the sanitary work in the army, and we cannot get on without them. But I think this is a mistake in the sanitary work as in the government of India. The sanitary work is the province of the Commanding Officer, and the representative of the Commanding Officer should visit my office, and the inspection should be made jointly, so that the reports that are made shall reach myself and the Commanding Officer straight and direct.

17. The Quartermaster represents not the executive side, but an important administrative side, if you please; but the command of English soldiers which, mind you, English soldiers are in our army, also implies great and vast sanitary responsibilities; and, therefore, throughout my service in India I have endeavoured in the regiments I was posted up with as senior Medical Officer, to get a Sanitary Officer as well as the Quartermaster to go round with my Medical Officer at these inspections. This system has been in every way excellent. You can get the work done well, and it is astonishing what a different thing sanitation becomes under such a condition.

18. The sanitary inspecting officer then, of the various batteries or regiments, make out their weekly reports of the sanitary inspections made on the Friday and Saturday, and on the Monday morning I myself had, when in India, and have every week here, a regular sanitary conference with the sanitary officers serving under my orders; that is to say, I meet all the Medical Officers of those regiments, and there is no sanitary question or shortcoming so far as my lights go (and I have had 29 years of a soldier's life) that is not fully and freely discussed, and I read over the diaries. If anything has gone wrong I say, "Have you written about this to the Commanding Officer?" The Medical Officer replies, "Yes, I have." "Then bring me the reply: What is it?" And I would say to officers commanding the various units that when Sanitary Medical Officers write letters to them, of course they look for an answer: but very constantly we wait and no answer comes. I have found the matter so difficult to deal with in some most sickly stations that I have been at, that I went to the trouble of getting a form printed, saying at the bottom, "Will you please favor me with an account of what you propose doing in this matter, so that I may fill up my own sanitary reports." I think such a sanitary report form much needed in our army.

19. *Sanitary Diaries.*—Having read the letters and the diary, I advise with the officers as to the course to be pursued. Should the Commanding Officer write back, and say, "I regret to say I am unable to carry out your suggestion on account of so-and-so;" then the matter, so far as it lies between those junior sanitary officers and the Commanding Officer, ceases; it passes to me then, and I myself write to the Commanding Officer of the regiment pointing out the necessity of such-and-such a suggestion; and when he replies, if it is a senior officer writing to me probably he may modify his opinion and the thing may be done, or he may reply, "I regret I cannot see any way to carry out the suggestion." Then the matter ceases between him and myself. I then write a letter to the Principal Medical Officer pointing out that

I have discussed the matter with the Commanding Officer, and that the men at such-and-such a station are working, and keeping them out of the work-and-such-and-such, and then the men coming to the station are working the evening because they have had to work, so no proper food, and that it causes me great trouble that I have requested him to consider the matter and advise me if he could modify it, but that he says it is not possible; and then I beg the Principal Medical Officer to consider the matter, and if he concurs with my views, I beg him to move the General Officer Commanding whether he can order the Commanding Officer to do so-and-so. Then the matter passes out of my hands and lies between the District Principal Medical Officer and the General Officer, and they discuss the matter. The General Officer may concur and order the suggestion to be carried out, or may not concur and the whole matter falls for a time into abeyance. These recommendations may refer to any possible matter in the wide range of sanitary duties.

20. *Quarterly Sanitary Returns.*—From the various weekly returns compiled by the Sanitary Medical Officers and myself, the Sanitary Officer of the garrison makes out every quarter a quarterly sanitary return dealing with every possible sanitary and health question; referring to the healthiness of the barrack-room, the over-crowding, the water-supply, the latrine arrangements, the clothing, the drills, the cooking, the food, and everything. And this report, together with the remarks of the Principal Medical Officer of the district, go in one report up to London to the Director-General of the Medical Department, and the latter then, as head of the medical service, considers the reports with his sanitary staff in London, and advises the Commander-in-Chief as to what he considers should be done. At the end of each year a Blue Book is published, dealing with the health and sanitary condition of the army, and this is sent to the War Minister and by him printed and presented to the Houses of Parliament. It embodies the statistics of the sickness of the army and the sanitary reports of the Principal Medical Officers of District; but I do not see in this Blue Book the final opinions of the Director-General of the Army Medical Department on the health of the army as a whole. The Blue Book contains the reports of the Principal Medical Officer of the Districts throughout the Empire, which the Director-General simply embodies and forwards on to the War Minister, and that official to Parliament.

21. *Director-General, A. H. D.*—I think myself that it would be a great thing if it were possible that the Director-General in London, who has the enormous benefit of receiving the reports of the Principal Medical Officers all over the world, should give a summing-up on the various sanitary matters that are put before him for the information of Parliament. This is an outline, I say, of how the sanitary side of the army works as regards its organization from the sanitary officer of a battery up to the Director-General, and the War Minister.

22. *Cubic Space in Barracks.*—I would now come back from these general remarks to the practical details of sanitary matters. Let us begin with the barracks accommodation of the soldier. Suppose you that in 1858,

After the experience in the Crimean War of 1854-55, a great Commission set, called the Sanitary Commission, and made some recommendations. They made a recommendation that every soldier in barracks should be allowed 600 cubic feet of air space. They found, when they examined the barracks at Constantinople, that the proportion allowed to each man was only 300 cubic feet, and they made the recommendation that each soldier in barracks should receive 600 cubic feet, and that ventilators should be placed in the room which would allow the air in that 600 cubic feet of space to be changed twice in one hour, so that a soldier might be able to receive 1,200 cubic feet of breathing air in the course of one hour. Now, why was this asked for? Was it by a fluke or chance? I say that I can no more modify my opinion as regards the cubic space for the soldier than any gunner here can modify his opinion as to the thickness of the parapet as regards the penetration of his shot. It is governed by a law. A human being to breathe healthily and well requires 2,600 cubic feet of air in the course of an hour, and the total "ration of air" that the soldier now receives from the country is only 1,200 cubic feet per hour, that is to say, far and away below the normal average of a healthy man.

23 *Over-crowding, Consumption.*—The result of the old over-crowding of barracks was always that it resulted in consumption, phthisis. This consumption, this destructive lung disease, was caused by the over-crowded men breathing in and out this poisoned air into the room and poisoning the air with carbonic acid gas; and, furthermore, and much worse, by pouring out of their lungs in the course of every day 80 grains of organic matter which is the waste material of the body. This poisonous atmosphere, which, mind, will poison an open wound if exposed to its pernicious influence, will cause a strong healthy man to sink into ill-health and give him consumption, and did in the old days kill off the splendid ante-Crimean guardsmen at the rate of 20 per 1,000 per annum. Put yourself, then, in our position as medical officers, who all of us know this, and who are taught at Netley the danger of this poisoned air, and say how can I be silent or how can my officers be silent, or how can you expect me to be silent and not write and point it out when anything like over-crowding occurs? I say that if I was to be negligent or silent I would be as much a traitor to the efficiency of the army as that officer in command of an outpost who sees the enemy approaching, and is such a poltroon and such a traitor as not to report it.

24. To us in the medical service, who see the evil results of over-crowding, there is an enormous force driving us onward in the sanitary struggle for the soldier. It is not that we may be more humane or more philanthropic than other officers, but if I stand in a garrison every morning and see the whole sick of that garrison pass through my hands and hear from every individual private soldier the reason why he is sick and why he has fallen ill, and if I hear from every soldier's wife the reason why she is ill, or how child is ill, I say that the force which upon me is an enormous and irresistible force, which is driving us

to make and work and, perhaps, suffer in the middle of your work for the soldier's sake.

25. An officer, who says in a gunner and who believes absolutely in his gun, will say, with, by reason of his very business, forget for a moment that behind the gun is the man who works the gun, and, stilling the horse in the man who is 10,000 times more valuable than the horse. The man is conscious, and we, hearing his story and seeing his condition, are irresistibly urged forward on the pathway of sanitary progress for his sake. We are urged forward, then, not only by the actual breakdown of the soldier's health, which we see for ourselves and by the reports of the soldiers who are actually our patients who tell us the reasons of their illness, but constantly the medical service is being made use of by officers of rank and standing to urge forward improvements or recommendations which they themselves hesitate to put before the authorities. How often have I said to such an officer, "You are using me to put this matter forward; why not represent it yourself? You have rank, standing and position; why come to me?" He will reply, "The medical service is independent, able to speak, and unless you assist we cannot succeed." I maintain, then, that General or even higher officers in high command, when they receive recommendations or suggestions from the medical department, may be, and often are, entirely unaware of the real sources of the recommendation.

26. The more hard or unyielding the General, the more is the medical service used to move him. How clear, how definite, how unassailable, should be the rank and status of the sanitary officer liable to the pressure of the upper and the nether millstone in the clear discharge of his duties to the army. Surely he forms a definite part of the army that cannot with any sense of justice be put aside. We in the medical service knowing this responsibility, knowing these heavy duties, knowing the various unseen currents acting upon us, and placing us in direct prominence as sanitary officials speaking for the good of the army, as a whole can never cease to claim defined and unassailable military status, not merely for our own personal sake, but for that army who in every rank, from the highest to the lowest, are at times compelled to have recourse to our assistance.

27. The army does not want a body of weak-kneed, trembling Medical Officers with defective status and shaky rank, but rather a highly-trained and thoroughly disciplined and independent body of sanitary advisers in deep sympathy with the army as a whole, and bringing all the help of modern scientific investigation to bear on the preservation of the health efficiency of that army, which, scattered over an enormous Empire, is fighting a trying battle with disease and death in peace and in war wherever the English flag is flying.

28. *Fresh Air and Discipline.*—Let us return now to purely sanitary details. The Sanitary Commission in 1856 fixed on 600 cubic feet of air space for the soldier, and they put in ventilators which enable this air to be changed twice within one hour. There is a law governing the size of the openings of the inlet and outlet ventilators which enables a certain fixed amount of air to come into the barrack-room, and these give the soldier

this delicate "ration of air." The air of the average badly ventilated barrack-room about 5 o'clock in the morning can become almost poisonous, and a horrible odour of organic matter from the soldier's body and bad air from his lungs, can and often does produce thoroughly deleterious atmosphere. It is as necessary to have a good system of ventilation in a barrack-room, so that the air may be changed, as it is necessary to have the barrack kitchen outside flushed by water. This flushing with fresh air-called ventilation is waiting to sweep away the poisonous organic matter so as to make the room sweet and fit for the soldier to live in. For whose sake? For all your sakes. And why? If the soldier sleeps for eight or nine hours in that bad atmosphere, when he rises in the morning he is in a semi-poisoned state, he does not feel fresh and fit for work, and what is the result? He looks about for drink as a stimulant. The soldier after a long night in that bad atmosphere, stupefied by bad gases, may also be below par in a nerve sense and be in a bad temper—that is to say, he is not fit and well as he should be. The difference of good and bad air in its action on ourselves is very well shown by the depressed state in which we feel ourselves on an Indian troopship, when coming up on deck in the morning from the stuffy cabin below stairs where we may have passed the night, and the feeling of freshness and elasticity we feel after sleeping in some well-ventilated Indian tent: in the one case we are in good temper and fit and fresh for work; in the other case we are below par and unfit for work. Why? Because in the troopship we are semi-poisoned by the poisonous gases and organic matter given off by the hundreds of people in the crowded 'tween decks below, and which drifts back into the officer's cabin and into pandemonium.

29. *The Ration of Air.*—The soldier, then, has a fixed and definite ration of air allowed him by the State. Just as he is allowed a "ration" of money, called pay, and a "ration" of food, and a "ration" of clothing, and a "ration" of water in the tropics to sustain his existence, so he is allowed by the regulations a "ration of air," and there is no more legal right to take away from him that defined ration of air by over crowding him, than there is to take away from him his pay, his food, or his clothing allowances. *We must never forget, also, that the ration of air of the soldier is in no sense a full ration.* If I were to sit down in a physiological laboratory and deal with the ration of air in a purely scientific and abstract manner, I would then say that on purely physiological grounds he requires 3,600 cubic feet of air per hour to keep him healthy and fit. The Sanitary Regulations, which were framed in 1880, and which still govern the army, were only tentative, and as the official working goes, "Only for the present time (1860)" only gives the soldier 1,200 cubic feet of air per hour; therefore he is to the bad the difference between 1,200 cubic feet and 3,600 cubic feet per hour.

30. In these bygone days, so wrongly called "the good old days," the terribly over-crowded state of the men caused the dreadful atmosphere of the barracks, bringing about air poisoning and ending in consumption. While the deaths in the civil population of the military age (30

to 40) were 10 per 1,000; in the splendid country of the line they were 12 per 1,000; in the regiments of Foot Guards they were 20 per 1,000, and in the infantry of the line 15 per 1,000, as against 10 per 1,000 of the same ages in the civil populations. That is to say, this elaborately turned out, heavily pipeclayed and absurdly dressed soldier of the old pre-Crimean day was dying of practically preventable destructive lung diseases, and the Army Medical Service up to 1858 had no power to say one word of advice or warning in this most serious death-rate.

(To be continued.)

PROFESSIONAL SECRECY AT HOME AND ABROAD.*

By MALCOLM MORRIS, F.R.C.S.

Editor, "The Practitioner."

THE result of a recent trial has been to bring into prominence the obligations and legal relations which exist between medical men and their patients with regard to facts learnt in the sick-room involving questions of professional secrecy. On this subject little has been written in this country, and the student has to turn to foreign literature, especially to that of France and of the United States, for a full discussion of the questions involved. We propose to consider briefly some of the obligations of professional secrecy as they obtain in this country, where the matter is not under statutory control, and in certain other countries where it is governed by legal enactments, at the same time giving a few actual cases in illustration of the points raised.

Ever since the practice of medicine has been an organized profession, the obligation devolving upon its members to regard as inviolable the secrets confided to them, and those to which they gained access during attendance on their patients, has been a generally-recognised tradition. This tradition was embodied in the well-known Oath of Hippocrates, of which the final paragraph runs as follows:—"Whatever in connection with my professional practice, or not in connection with it, I see or hear in the life of men which ought not to be spoken of abroad I will not divulge, as reckoning that all such should be kept secret. While I continue to keep this Oath unviolated may it be granted to me to enjoy life and the practice of the art respected by all men in all times! But should I trespass and violate this Oath, may the reverse be my lot!" In a similar manner the faculty of medicine of Paris embodied this tradition as to the obligation of professional secrecy very concisely in the following formula, which was promulgated in 1566:—"Ægrorum Arcana, visa, audita, intellecta, eliminat nemo." It will now be necessary to consider how far this tradition has been modified in modern times, and to what extent it has received legal sanction.

In Great Britain and in most of the States of the American Union medical men, when they appear in a court of law, can be compelled under oath to divulge such confidences, rendering themselves liable in case of refusal to committal to prison for contempt. Medical men in this country are thus, from a legal point of view

*Reprinted from *The Practitioner* by request.

in exactly the same position with respect to secrets confided to them in the practice of their profession, as the rest of the world is with respect to ordinary secrets.

On the other hand, in most European countries and in a few of the States of the American Union, professional secrecy has been made the subject of special enactments. In France the betrayal of professional confidence is of itself a punishable offence.

It will now be useful to compare, with some little detail, the working of these two systems as regards the obligation of professional secrecy involved under the two following heads:—(a) The obligations to retain secrets, and the consequences of divulging them; and (b) the obligations to divulge secrets, and the consequences of retaining them.

(a) *The obligations to retain secrets, and the consequences of divulging them.*—In France, according to Professor BROUARDEL, there are, broadly speaking, three classes of facts which always involve the obligation of secrecy: (1) Facts with regard to the nature of the disease, amongst which are (a) those known as "maladies secrètes," or, in other words, venereal diseases; and (b) diseases which are either known or supposed to be hereditary, such as epilepsy, tuberculosis, and mental alienation. (2) Facts with respect to diseases, which usually lead to a more or less rapid death. (3) Facts which, though not in their nature secret, become so under special circumstances. For example, the birth of a child is not, as a rule, to be regarded as a secret—in fact, medical men in France are bound under penalty to the authorities to notify any birth occurring in their practice in the absence of the father; but where a girl who has been seduced gives birth to a child, the medical man, in reporting the birth, does not give the name of either the father or the mother; nor does he give the address of the house in which the child was born. If he divulged any of these facts, he would render himself liable to a penalty. Again, cholera is not a secret disease; but in the case of a man dying of cholera in a house of ill-fame, the fact of his having done so may not be divulged by his medical attendants. In such a case it is usually assumed that he has been attacked by the disease in the street, and thence carried to a hospital—a form of polite fiction which in Paris is connived at by the Prefecture of Police.

The rigour with which the law in France with respect to professional secrecy is enforced is well illustrated by the case of Dr. WATELET, who, in 1884, in order to defend himself against false accusations with respect to his treatment of M. BASTIEN LEPAGE, during his last illness, wrote a letter to *L. Matin*. In this letter he described the disease, the operation, and the result of the subsequent examination of a tumour removed. For the publication of this letter he was prosecuted and condemned to a fine of 100 francs, and the conviction was upheld on appeal.

In addition to the penalties under the penal code, medical men in France are also liable to civil actions if their betrayal of professional confidence can be shown to have caused the aggrieved party technical damage.

In this country, if a medical man voluntarily divulges secrets acquired in the course of his profession, he does so at his own risk, for the secret is that of the patient who has a *prima facie* right in law to require that it shall not,

under ordinary circumstances, be divulged to any third party. If he can show that he has suffered any damage in consequence of the publication of the secret, he is entitled to redress. Supposing that action taken by the patient should be for defamation of character or for libel or slander, the medical man under certain circumstances might plead "justification"—that is to say, he might set up as a defence to the action "that the words spoken or written were true in substance and in fact." Whether this plea would be successful or not would depend on the view taken of the circumstances by the jury. If, however, it should not be thought desirable to enter the plea of "justification," the question of "privilege" might arise. What circumstances exactly constitute privilege when a medical man communicates a professional secret to a third party has not been authoritatively decided in this country; but, to take an extreme case, there is little question that where a doctor, having ascertained in the ordinary course of his profession that his daughter's intended husband was suffering from syphilis, communicated the fact to his daughter, with a view to preventing the marriage, such a communication would be regarded as privileged; whereas in France, under precisely similar circumstances, a medical man would have rendered himself liable to penalties for divulging a professional secret.

In France, in addition to the various classes of cases which have already been referred to, and in which the necessity for professional secrecy is regarded as absolute, there are a large number of other cases in which a certain amount of discretion is permitted to the medical man, as, for example, in questions of life assurance and death certification. With regard to life assurance there has been much discussion and litigation in France. It has been held that under exceptional circumstances the family doctor may disclose facts with respect to the person to be assured, but not where these have any bearing upon the family history. As a matter of practice, however, at the present time, it is considered a breach of professional secrecy for the family doctor to disclose any facts with regard to the personal or family history of his patient, and the death of the latter does not release him from this obligation. The companies' interests are considered to be sufficiently protected by the report of their own medical examiner. In the case of certification of the cause of death again, a certain amount of latitude is allowed to medical men. Still, here there are a large number of diseases where, if the doctor certifies as to the actual cause of death, he is considered as guilty of a breach of professional secrecy. These instances will suffice to show the difference between the practice in France and in England.

(b) *The obligations to divulge secrets and the consequences of retaining them.*—With regard to this heading, it may be stated in general terms that in France the physician is bound to divulge professional secrets in those cases where their retention involves plots against the State, or against the lives and welfare of individuals—in cases, for example, of poisoning, abuse of children, and criminal abortion—and with regard to these subjects the obligations of the medical man in England are the same. A failure to divulge would cause him to be considered an accessory, and render him liable to penalties. The medical man in France is also bound under penalties

...these people, and the people which have

in New York and certain other of the American States it has been enacted that "a person duly authorized to practice physics or surgery shall not be allowed to disclose any information which he acquired in attending a patient in a professional capacity." In the States where this enactment is in force, the position of medical men in a court of law is practically the same as in France. The Court of Appeal has decided that all information must be regarded as confidential which has been acquired by the physician in his professional attendance, whether personally observed by him in examining the patient or imparted to him by anyone in order to enable him to act in his professional capacity, and that, too, although it might not, in fact, aid him to prescribe.

From the foregoing remarks, which have touched upon some only of the questions involved in the subject of professional secrecy, it will have been seen what a wide difference exists between the strictness with which the old tradition is still adhered to in Europe and elsewhere, and the great modification which it has undergone in our own country. While not wishing to abandon our greater freedom and feeling that the interests of patients may be safely left in the hands of their medical attendants, we consider that the rule with respect to the disclosure of professional secrets in court is, in the words of Best ("Law of Evidence," p. 581), "a rule harsh in itself and of questionable policy."

ALCOHOL AND THE FIGHTING

By JAMES LANCE BOWEN

Bonding

We shall open with a few prefatory remarks.

The judicious use of alcohol in disease need not be much discussed here. As an energy-producer it is unequalled. By its rapid oxidation in the system, it provokes work and so aids invigoration and animation. But since every degree of labor must necessarily be followed by a like degree of weariness, this can neither be counted an advantage nor a disadvantage: the system, under the influence of alcohol, is made to do in a short time what it would otherwise take a longer time to accomplish.

Whatever may be the real advantages or disadvantages attendant upon the use of alcohol in disease, certain advantages, which will appear to outweigh all disadvantages, call for remark : it exercises a powerful germicidal influence, and it doubtless possesses the power of suspending those processes of fermentation that take place in the blood during disease. In all the fevers, therefore, its action being such, it will tend to lower the temperature of the blood ; while in diseases where the temperature has fallen very low, as in cholera, its ready oxidation will tend to warm the system ; thus, in either case, leading to a possible cure.

But in health the use of alcohol is a practice to be utterly condemned. In many instances it is taken to create an appetite for food. The result is that it so provokes the appetite, that more food than is necessary is consumed; with the surplus the healthy appetite disappears; and alcohol becomes absolutely necessary to recall it.

If men fasted less between meals in proportion as they worked more, their appetite for food would never desert them. By long fasts between meals, the food supply gets exhausted, the temperature falls below the normal, and the appetite disappears. The loss of appetite is due to a want of food, and easily digested food alone, taken at intervals in small quantities, will restore it. Alcohol would only create a false appetite, whilst it would also weaken the digestive power after its action has ceased.

In many cases alcohol is taken to overcome depression, but since depression is always more or less connected with a lack of food supply or a loss of appetite, food alone will permanently overcome it. Alcohol will stimulate no doubt, but that is only for a time, after which depression will follow.

The chief tendency of alcohol is to usurp the places of oxidation of the carbon or fat particles of the blood, and its oxidation is so rapid, that the lungs, with all the other organs in the animal economy, are excited to unnecessary over-exertion by it.

We all know that acetic acid is produced by the oxidation of alcohol, and there can be no doubt that this alcohol, as it is being oxidized in the system, is being converted into acetic acid, but a very pleasant acid to gulp down at a draught, though the acetic acid may be converted into so many intermediates as to be harmless by gulping down alcohol instead.

...reading 2.50 grams injury

There is a considerable difference between the Chinese and the Americans. The Chinese are not from a purely Confucian background. The Confucius doctrine is based on personal experience, observation, and the consensus of others.

With these prefatory remarks always in view, we shall begin our essay.

Few men there are who are not fond of their glass. Coming home from work the weary clerk and the tired mechanic take it for the least favor that it winks upon them; instantly and bodily, it dissipates their sulky spirits and makes them feel hale and hearty once more; it loosens the strings of their speech and strengthens their languishing hopes; it brightens their prospects of life and removes all their various doubts.

But wait: the tonic effect has passed away; their cystids begin to droop, and, sleep soon overcomes their exhausted natures.

Splendid, indeed, is this tonic effect of the glass whose contents count thousands to eternal damnation ; laudable, indeed, is it to cheat nature of her lawful demands for rest by postponing them for a time ; and glorious, indeed, is it to slip into a sleep whose tranquility is to be disturbed by the Demon that lurks within the glass.

Say I true! The labor of the mechanic and the
 clerk are depressing; they come home weary and ex-
 hausted; that infernal glass of liquor goes down their
 throats; they feel rejuvenated; the depression of their
 day's labor, however, still lingers within them; soon the
 effect of the liquor passes away; a greater weariness
 than before now seizes them—a weariness produced by
 the combined weariness brought about by their day's
 labor and by the action of the stimulus upon their
 nerve-centres; and they drop asleep, and sleep the sleep
 of the laboring man combined with the sleep of the
 drunkard.

So much good then, does the so-called tonic dose of alcohol exert upon a tired system. It exhausts that system more, and can hence do no good.

And regularly every day is the luxury of that one glass indulged in till its luxurious effects are no longer felt. The system has become so accustomed to it, that the abundant effect which it had created upon that system at the beginning is now so largely felt. Something must then be done to realize that effect. The dose must be increased, and increased it is necessarily, with the result that an effect, similar to that experienced at the beginning, is produced. The effect, therefore, of two glasses upon the system is now quite the same as that which was produced when the individual was accustomed only one glass. But, as time wears on and the system gets thoroughly accustomed to these two daily glasses, a third is added to be felt, and on between is the third, increased because necessary to produce that effect. And so time and a third glass is added on, and so on, until the dose of the two previous doses, plus the third dose or all a quantity, large

Now, much more than in any other circumstance, is taking cognizance of these facts and their consequences called for. When one whose name it is to take the lead in this matter, that certain things are being done to the detriment of the body, why should the thing itself be left to itself? Why move, not even without adding a grain of salt, when his work is over, without, in taking it, experience the sensation of exhaustion? But this individual, though feeling weak, comes to recognize why such exhaustion is felt. It therefore shows that he is unbalanced, and that his system lays a state below the normal one. In his language, it indicates that his tissues have undergone such a change as to cease to be stimulated by the accustomed dose. If, then, the tissues be no longer accustomed to such action on the strength of the usual quantity, they must experience a sensation of depression; since the alcohol must not one day cease either. It has ceased to stimulate; therefore it then begins to depress. And experience teaches us the truth of this. That one gives a day, to which our subject has grown pathologically accustomed, no longer exhilarates his mind, but stupefies it, at the same time that it exercises a depressing influence upon his general system. He comes home from work, feeling that healthy sensation of weariness which springs from honest toil; down goes the balling dose, instant depression of spirits overcomes him, and he feels as sick of life as any set after a carousal.

Certain injury then, is being done to the system of such an individual. So soon as he takes his daily glass his system drops below the normal standard. To bring it up to normal or above he must therefore do one of two things—either entirely abandon the habit he has acquired and abide his time, or quicken his system into a state above the normal standard by gradually increasing the usual quantity consumed.

In all cases it is wiser to follow the former course; but in the majority of cases the latter is chosen.

Now, where lies the essential difference between the man that takes his one glass a day and derives no sensible pleasure therefrom, and him that has learned the art of taking more, restricting himself, however, solely to that quantity necessary to produce exhilaration in him? Merely in this,—While one takes a delight in exalting his spirits every day, the other depresses his.

Defining a drunkard, for purposes of this essay, as one who is more or less under the influence of alcohol for a time or for all time, we have, up to this point, made up two classes of them—one class, including all those who, beginning with one glass every day and deriving a certain amount of pleasure therefrom, gradually increase the quantity so soon as the pleasure, which they get derived from one glass alone, ceases to be any longer all; and the other class, comprising all those who continue to take their one glass every day, even after the pleasure which they had experienced at the beginning, no longer ceased to be felt.

The former, studying exaltation alone, up to a certain point, expect not to give themselves more quickly than the latter class who consider only depression.

By following the practice of the former, it will take a man all his life-time before through a day of arduous spirit he is intellectually exalted, his mind and reason are exalted. He experiences that intellectual exaltation, and he stops there; while the other is content with intellectual depression alone.

The former class may therefore be classed under the head of moderate drunkards, and the latter under the head of simple drunkards.

But such men are rare, very rare. Many there are who profess to be as strict as they in their habits, but such men are rare. They would boastfully tell you that they are quite content with a glass of liquor a day, and would advise you to be like them; but if you were to ask them to discuss a bottle of whiskey with you, they would very readily do so, so long as they are spared the expense of paying for it. They indulge in a fondness for alcohol, but their wives or their purses would not allow them more than a limited quantity per day. Those who love their glass will also be generally found to love their bottle.

Now comes a third class of drunkards, more notorious than the former. They are the occasional drunkards, consisting of men who, ignorant of the art of drinking, on grand occasions guzzle down large quantities of liquor, like so many horse-keepers, without knowing when to stop, and also of men who are prepared to drink whenever an opportunity for doing so presents itself.

Any sane man now would say, that of the three classes enumerated above, the last class are apt to injure themselves more quickly and more surely than the former two; for, whereas the former have acquired habits to which they regularly adhere, the latter, having formed no such habits whatever, would be always prone to the danger of taking more than they are able to bear.

Experience emphasises the truth of this. On grand occasions, these occasional wine-bibbers, in most instances, fall into this error. After the intellectual exaltation produced by the first or second glass has begun to wane, they are prompted to take another, which they unflinchingly do, to keep up their spirits as they imagine. But this second or third glass falls short of the desired result, and a third or a fourth glass becomes necessary. Then follows the horse-keeper style of drinking, all for the object of rousing the intellect. But this is impossible, since the intellectual exaltation experienced at the beginning is now fast becoming intellectual depression; the victims rave foolishly over their cups, their reason fast going from them, and their power of voluntary control is going too; till at last, their brains reeling, their eyes swimming, their ears tingling, their knees trembling, they either drop where they are and mess the place, or stagger through the doorway to their carriages and do it there, or at their homes with more modesty and comfort.

Some there are, no doubt, who avoid falling into this error; but they form the exception to the rule.

Well, to continue. Letting alone the unnatural slumber into which these occasional boozards fall after a debauch, with their lungs half performing their duty, they awake in the morning with every organ in their body thorough-

ly congested and their nerves all unstrung. Their head is aching, their sight, before which fast coming dark spots, dim, their hearing dull, their liver and their kidneys inactive, their pulse feeble, their respiration sluggish, their temperature below the normal, the veins of their hands and feet all swollen and distended to their utmost, with an abnormal quantity of waste material waiting to be burnt off and removed from the system, and their appetites gone.

After some hours a slow fever sets in—a fever owing its origin most probably to the fermentation of the waste material in the blood—whose subsidence marks the beginning of recovery from all ill-effects.

The occasional drunkards are therefore exposed to a very grave danger. They are, with the opomaniacs, the most prone to fall into that deranged state of mind and body known as *delirium tremens*: by suddenly getting drunk and as suddenly quitting drink, such individuals become predisposed to this affection.

But this danger, the cause of which may be ascribed either to an abnormal fall in the temperature of the blood, or to the fever spoken of above, can always be averted by light nourishing food, taken in small quantities at intervals. An exhausted system always needs fresh food, and this is especially so in the case of him who has just awaked from a drunken sleep. The ill-digested food of the previous night is not food to his system, but poison. His digestion has been so hurried by the alcohol, that its ultimate products are unfit for assimilation. The unusual quantity of fat present in the blood of drunkards proves this, instead of the fat being in a fine state of division, it is coarse, and therefore less easily oxidisable. What must be the state of the other products! Fresh food therefore becomes absolutely necessary, but this time without alcohol. Its orderly digestion, though slow at first, will strengthen the natural resources of his system and so avert the "horror."

Now comes another class of drunkards. Out of the ranks of the occasional, spring the opomaniacs—men who drink as soon as they are seized by an impulse to do so. The craving suddenly seizes them; down goes the liquor, glass after glass, in quick succession, vomiting ensues, almost immediately after down goes another glass, and the booze is resumed and kept on for days and days; till the individual completely fuddled and seized with an entire disgust for liquor, recalls himself to his duty in life. Up to an indefinite period after this he remains trustworthy and sober, not allowing even a drop to pass his lips, till his evil genius once more leads him to the threshold of the tavern and once more steepes his senses in liquor, this time more thoroughly than the last.

Such a man, sir, will come to such a pass in life as to be thrust into the Government workhouse, after having pawned even the last good rag to his back.

There, in the workhouse, he will find much work and ample food for reflection: if he fail within a term of six months to muster up ten solid rupees to show to the authorities in order to regain his liberty, or if he fail to convince them that he has found a situation, he will find himself condemned to undergo a term of imprison-

and you will find that, however, and stronger for it, in time take it, and the time may yet come when you will find that you cannot do without it; when your morals shall go to the dogs, and your strength and your substance be counted for naught.

A weary sight to find oneself in:

No man knows the insidious nature of alcohol till he has learned to know it; and then, as is often the case he will find that his knowledge comes too late. So boast not of thyself, O man, whoever thou art, by saying that one glass of wine is enough for thee: the day may yet come when thou wilt not suffice thee!

But where is the good of preaching: it is just as well to advise the devil to turn over a new leaf, as to ask a man to mend his ways.

Last of all comes the constant class of drunkards, consisting of those who are continually fuddled with liquor, beginning betimes in the morning and leaving off late at night.

The systems of these men have fallen into such a state, that they cannot go without alcohol.

Their digestive powers have become so impaired, by alternate stimulation and depression, that they would entirely cease to act, were it not for the alcohol. It is clear therefore, from this, that a time will arrive when no amount of alcohol will any longer rouse the digestive powers, when not even croton oil will stimulate them to action, and when the hapless victim will die of starvation! God help such individuals!

They are generally a quiet and sly set of men, moving callously through life; while the occasional drunkards, under the influence of liquor, are boisterous and unreasoning.

It is safer to be in the company of the former set of men than in that of the latter, where the even beauty of one's face is in constant danger of being marred.

The occasional drunkard is always in greater danger of coming to sudden grief than the constant.

If the constant drunkard possesses a big brain, as in most cases he does, he will still have that spirit left within him to go and do his duty, but the occasional drunkard, never.

The constant drunkard is a man to be pitied, not despised. Many are the resolutions that he makes to quit the evil habit, but his besetting sin is too great for him to overcome.

He is a slave to the habit, and it is as easy for him to regain his freedom from the curse, as it is for a man, condemned by the highest authority to pay the full penalty of the law, to escape.

Men who are given to using their brains or their hands overmuch are most apt to indulge in a fondness for alcohol, the worn muscle is strengthened thereby, and the tired brain is roused; but extra compensation must be made afterwards for such expenditures of force. The tired muscle no doubt will be strengthened, and the weary man roused to renewed energy, but the next day a larger quantity of alcohol will be necessary to produce the same results at the same time, or more rest will become imperative.

Hence the insidious nature of alcohol.

It offers itself as a specious renovator to the weary mind and the tired body. Avoid it for its insidious nature

and you will find that, however, and stronger for it, in time take it, and the time may yet come when you will find that you cannot do without it; when your morals shall go to the dogs, and your strength and your substance be counted for naught.

How does it act upon the system? In a most unnatural manner. Not only does it upset the stomach, not only does it lead to atrophy of the liver, not only does it interfere with the regular secretions of the digestive juices, not only does it overwork the kidneys, not only does it finally make the blood less coagulable, not only does it intensify the beating of the heart, not only does it excite the brain, and the whole nervous system to extraction, but it also deprives the system of its proper share of oxygen.

The loss of appetite the next day, and the unhealthy congestion of every important organ of the body proves this.

The alcohol, surrounding the waste and fatty products of the blood, as it is swept into the lungs, is burnt off first on account of its greater appetite for oxygen; what little oxygen remains is left to do its best with the waste material of the blood; in consequence, much of this material is left unburnt; and as the exhaustion of the lungs through overwork increases and the supply of oxygen grows less and less, the alcohol alone burns and the waste material, unburnt and increasing in quantity, is allowed to circulate freely through the blood, poisoning that most important fluid and rendering it almost unfit for the maintenance of life.

Gradually as time rolls on and the practice is kept up, the waste products begin to accumulate about various organs of the body, being deposited there as fat—fat within the heart, within the kidneys, within the liver, within the tissues of the abdomen, and in fact, everywhere, but in the right place.

And as the weakness of the lungs increases more and more, and the oxygen inspired grows less and less, the alcohol, not being entirely oxidated, circulates through the system and begins the task of depriving the arterial blood of most of its oxygen, thus diminishing the supply needed for the support of the muscles, and setting up that diseased state in a muscle known as fatty degeneration.

But the above is not all that happens. The brain and the nervous system also suffer, and insanity or paralysis may result—the victim may get permanently mad, or the powers of some important limbs or members of his body may get entirely paralysed.

But nothing can be compared to the damage done to the lungs, the source and well-spring of life. By continual drinking, they, with their motary muscles, become weaker and weaker, till at last they are scarcely able to perform the most important duty assigned to them, that of keeping the individual in life and health and of taking care in a manner of all the other organs in his body. Take care of your lungs, and your system, in all its parts, will take care of itself! All the evils, to all the

...the body, and the mind is...

...will do you no good, and that continual
...will do you no good.

Take a glass of your wine and your bodies
...; and, if alcohol can have such an effect
...and a strong body, its final effect upon
...and exhausted body must be disas-
...trous.

Alcohol acts upon the organism like a most insidious
disease, by depriving its various parts of their due share
of oxygen, thus rendering them almost unfit to perform
their several duties. In their endeavour to acquire a
sufficient quantity of the vitalising fluid, their actions
become labored, with the result that weariness soon
follows. Oxygen gas, administered occasionally for five
minutes at a time, by thoroughly arterialisating the blood,
will alone overcome this evil; the actions of the various
organs will become less labored, and the work of life
will be carried on at a more leisurely pace, the evils
attendant upon alcoholism will gradually disappear and
the craving for liquor will soon cease to exist.

The air that we breathe is mainly a mixture of oxygen
and nitrogen; if, in disease, the reception of this nitrogen
into the air cells can be prevented, the capacity of those
cells for oxygen will be more than doubled; the adminis-
tration of pure oxygen gas then will diminish the labor
attendant upon respiration and set up a like action in all
the other organs of the body.

No more need be said now on this subject. It is to
be hoped that all those who are prone to tipping will
ponder over these words in their hearts, and will finally
each join with me in saying with Stender, in the "Merry
Wives of Windsor." If I be drunk, I'll be drunk with
those that have the fear of God, and not with drunken
knaves;" in other words, I'll go and get drunk with the
godly!!!—Alan!

NATURE OF THE NIGHT TERRORS OF INFANCY.

THE condition described under the name of night terrors
is merely a manifestation of infantile neurasthenia, and is
principally observed in nervous, irritable, and impressionable
children, whose sleep is light and restless, and who are easily
disturbed. It is one of the manifestations of want of nerve
control, resembling in this respect the nocturnal incontinence
of urine. Under these circumstances, with a badly balanced
nervous system, the least excitement, which would have no
effect on a healthy subject, will suffice to produce a dream
full of the most terrifying suggestions. Another point of
resemblance with neurasthenia is furnished by the headaches,
palpitations, and easily induced gastric distress which the
subjects of these conditions show. In a certain number of these
cases the children manifest evidence of hyperæmia, of hypo-
chondriasis, and ultimately even of nervous epilepsy. The
treatment is the same as that resorted to in neurasthenia,
namely, abstinence and hygiene. If the child cannot sleeping
alone, he should not be compelled to do so, and, unless danger
threaten the brain and chloral, may be administered.—
Brit. Med. Jour.

A MIRROR OF ILLNESS.

LIVER ABSCESS: NATURE, CAUSE, DRAINAGE, AND CURE.

By SUBSERGEON-MAJOR H. E. WOODWARD, F.R.C.S.

Irregular Force, 1899.

GIRDHARI MINA, sepoy of the 1st Buffs, aged 22, a
youth of good build and constitution, was on the night of the
slight eczema in August last. He was admitted on 21st October 1899 with a small
abscess on the back of the right hand, just above enough
to procure his admission to hospital.

The next day, 22nd October, his evening temperature
ran up to 102.5 and continued with slight remissions for
eight days. Previous to admission he had had no fever.
(It may as well be mentioned here that there is no con-
nection, as far as is known, between the abscess of the
hand, which healed in a few days, and the subsequent
liver abscess).

On 24th October, he complained for the first time of
pain along the lower border of the liver. Examination
showed no enlargement or tenderness of that organ.
Fomentations were applied and quinine in doses of 5 grs.
administered during the remissions. His temperature
fell to 99° on 31st October and continued below 100° until
10th November. From this date until 30th November his
temperature chart shows evening rises to 102°, 103° and on
two occasions to 104° with morning falls to 101°, 100°
and 99°. On no occasion have rigors been present. During
this period his general health has been fairly good; he has
complained of no pain, and with exception of the nightly
fever of no discomfort.

Present state, 30th November.—No pain anywhere; feels
fairly well except for nightly fever; tongue clean, moist;
appetite fair; bowels open daily, sometimes loose, some-
times bound; always pale in color; no cough or chest
symptoms. Physical examination of chest reveals nothing
special in abdomen; some enlargement of the liver, which
since 10th November has been neither painful nor tender,
is observed for the first time. Upper border of liver dul-
ness reaches to 5th space in right nipple line; lower border,
which can be distinctly felt, reaches two inches breadth
below the costal margin.

15th December.—Patient continues to have nightly fever
without rigors reaching 101°, 102°, or 103° and falling to
100° and 99° in the mornings. The tongue continues clean
and his appetite good, but the prolonged fever for nearly
eight weeks is telling on him, and he is looking thin
and anxious; pulse 88; or so in the morning.

20th December.—For the past three days he has had pain
and tenderness over the liver. The pain is of a stitch-
like character, and there is marked tenderness in the flank
and over the lower ribs. Still no rigors. Morning aban-
doned to "liver abscess."

30th December.—The 7th, 8th, and 9th intercostal spaces
in the anterior and mid axillary lines show slight bulging
compared with the opposite side, though there is no dis-
tinct bulging.

31st December. Operation for Abscess of Liver, Drain
Irregular Force.—Patient's skin having been well scrub-

the aspirator needle was introduced in the 7th rib, 1 inch from the mid axillary line, where the pleura was punctured, and then gradually inserted and directed upwards into the liver. When the point of the needle (4 inches) had been inserted, cloudy chocolate colored pus escaped into the air-exhausted bottle. The needle being left in, a 2-inch incision was made directly over the 7th rib in proximity of the guiding aspirator needle; the rib was cleaned with a peritoneum elevator, cut through in two places with a bone forceps and an inch of the rib removed. The needle being still used as a guide, the pleura and diaphragm which appeared adherent to the outer surface of the liver was next cut through. The knife being discarded, a closed polypus forceps was thrust through the liver substance along the border of the aspirator needle till the abscess was reached. No hemorrhage occurred. The blades of the polypus forceps were fully expanded, the needle withdrawn, and the hole dilated with the finger. Eighteen ounces of dark chocolate colored pus escaped. The cavity was next explored with a long silver probe, and was found to extend backwards and downwards in the substance of the right lobe.

A large steel india-rubber drainage tube was slid over the guiding probe; the probe withdrawn and iodoform dusted over the wound. The side was well packed with salicylate wool, and fastened with a broad body bandage. Patient stood the operation which lasted a quarter of an hour, well. In three hours the discharge had come through and he was again dressed as before. Evening temperature 100.5.

22nd December.—Evening temperature 100 only; much pus from tube; tongue clear and moist; bowels regular.

After this he was dressed every day; about one or two ounces of thick stringy chocolate colored pus escaping at each dressing. On 10th January temperature went up to 102°, pulse 100, rigor 24. Salicylate wool discontinued and wound dressed daily with tar tow. Tube shortened.

15th January.—Temperature ran up in evening to 108. It now appears that as the abscess extends into the posterior portion of the liver, that this incision was made rather too anteriorly to insure perfect drainage. To remedy this the patient is made to lie on the right side and sometimes in the prone position.

25th January.—Patient is much better. Pus escapes freely, and is becoming thinner in consistence and not so dark colored. Throughout the case the wound has continued perfectly aseptic; the cavity has never been syringed or washed out. The skin around has been washed daily with soap and water, smeared with carbolic lotion and iodoform has been blown into the wound. The tube has been taken out and washed daily. Since operation has been fed on milk & Oat. Gruel, soup and later bread and vegetables, post since 7th, daily.

30th January.—Owing the 8th and 9th ribs in the mid axillary line a sinus tract is obtained by puncturing over a limited area, behind the wound corresponding with the abscess cavity.

31st January.—The sinus tract and drainage tube now close. A slight fever has been continued. Temperature 98 or 99 every morning, rising to 100 or 100.5 every evening since 15th January. Patient's general health is much improved. He can now walk without lagging, sleep, appetite good, bowels regular. Throughout the case he has been cheery and hopeful.

2nd February.—Pus about 50 cubic inches and has assumed a creamy appearance. Temperature 98.5 in evening.

27th February.—No discharge. Skin taken out, condition of patient excellent. Putting to rest.

2nd March.—Wound quite healed. Patient perfectly well. After two months sick leave he regains strength for duty. Since which from sick leave he has been perfectly well and has performed his duties as a soldier perfectly and is now one of the strongest men in the regiment. (July 1897.)

This case shows the history of a liver abscess "ab initio."

The symptoms and signs were obscure for six weeks, nothing but continuous nightly fever, with no liver symptoms except some slight pain for a few days. Also shows value of operation of incision and full drainage as soon as the diagnosis is established and presence of pus proved by the needle.

CHRONIC OTORRHOE, FOLLOWED BY BRAIN ABSCESS AND DEATH.

By N. C. CHATTERJEE, L.R.C.S.

Medical Officer, E. I. R. Hospital, Madras.

On the 10th of December 1895, Mrs. ———— aged 26 years, at the time 5 months pregnant, had a severe fall, hurting herself very much. Shortly after, she complained of severe pain in the small of the back and a sort of catching pain on the left side of the lower abdomen. She had miscarried once owing to a somewhat similar fall during the third month of pregnancy. On examination, I found nothing to be anxious about. I advised her to stay in bed as long as the pain lasted, and directed belladonna to be applied externally over the small of the back. I further noticed that her right ear was running and that she was a little hard of hearing in that ear. Being questioned about it, she said that it was chronic and used to appear and disappear at intervals. She had taken medicines for years while in England but without any relief. I tried to persuade her not to neglect it, but it was of no use; she was tired of trying different measures. On the 20th of the same month I was again called in and was told that pain, &c., consequent on the fall had entirely disappeared but that her right ear had been paining fearfully during the last four days. The canal of the ear, on examination, was found completely blocked up with thick white matter, which was very offensive. It was with great difficulty removed by syringing with a solution of Coccy's fluid and tepid water. Equal portions of borax and iodoform were blown into the ear, which was then stopped with borax wool and

the night. This relieved her to some extent, the pain and discharges were decidedly less on the following morning. The same treatment was continued, and on the 24th there was neither pain nor discharge. The auditory canal being normally dry, the bandage was kept on, but the blowing in of the powder was discontinued owing to the severity of the pain and consequent weakness. The patient was, on the 26th, advised to lay up in bed again. At 6 A.M. on the 26th a lady called for me in great haste and said that Mrs. — had just fainted, previous to which she seemed to have had an attack of ague. I found the patient in a strong fit of ague. She was conscious but could not speak. By signs she expressed that she was in great agony, severe fixed pain in the back and right front of the head. Shortly after the rigor stopped, but vomiting started, the slightest movement made the pain unbearable and the vomiting worse, though it was not preceded by any sick feeling. The right ear, which was quite dry the day before, was found filled with non-offensive purulent discharge. I was at a loss to understand how this change had come about so suddenly. The husband said that his wife thinking herself all right, did not stay in bed after I had left, but had been busy in arranging things to receive some friends who were expected the following morning. At 3 A.M. she went to bed but could not sleep on account of headache.

The symptoms led me to conclude that neglect and carelessness on the part of the patient had not only brought on a relapse but had implicated the brain. As inflammation of the brain often ends fatally, a couple of European doctors were at my suggestion brought in for consultation. After seeing the patient, they agreed with me as to the course of treatment given.

At 8 A.M., on the 25th, the temperature was 100·6, pulse 120, soft and weak, bowels bound, extremities cold.

Treatment.—The bowels were at once moved by soap water enema, but did not serve the purpose properly.

2. Black Draught ... 3iss. at once.

3. 5 Large leeches on the right forehead and temple.

4. Hot water bottles to both feet.

5. The ear was dressed as before. Complete rest in bed: the room was kept as quiet as possible.

At 1 P.M. temperature 101, pulse 120. Leech-bites were allowed to bleed. Had one semi-liquid stool, headache much the same.

Diet, milk and Brand's extract of chicken.

4. P.M.—No improvement, is much the same state.

8. P.M.—No improvement, is much the same state.

The next day she was taken to the General Hospital, Calcutta, where she died on the 29th December 1896. Post-mortem examination revealed, as I learned afterwards, that she had a suppurative abscess in the cerebellum.

GUNSHOT WOUND OF HEART.*

BY SURGEON-LIEUTENANT-COLONEL A. T. SLOANETT, A.M.S.

Senior Medical Officer, Alexandria.

At the Musketry Camp at Aboukir at 11 A.M. on September 22nd 1897, a corporal on duty as a marker in the mantlets at the rifle range was struck by a splinter of a bullet (Lee-Metford), which is supposed to have splashed back from the target. The man was sitting in a stooping position at the time, with his arms crossed and resting on his knees. On feeling himself wounded (he afterwards said it seemed as if someone had hit him with a whip on the chest), he got up, and, quite unaided, walked a distance of some 600 yards to the camp, which he just managed to reach when he fainted, and was carried to the hospital tent in a state of collapse. The medical officer in charge of the camp saw him immediately, and found that there was a wound of the chest situated between the fourth and fifth costal cartilages, 2 inches to the inner side of the left nipple.

On examination the external wound was found to be semilunar, $\frac{3}{4}$ inch long and $\frac{1}{2}$ inch wide, with clean-cut edges. On carefully probing the wound was found to lead into the thoracic cavity; no trace of a bullet could be detected; hæmorrhage was free.

The man recovered consciousness after about an hour but was extremely weak, and suffered from hiccough, nausea, and frequent vomiting. He was kept absolutely quiet, and everything possible was done to keep his strength up, but he gradually sank, and died at 1 A.M. on 28th September.

At the necropsy the chest was carefully opened. The pericardium, which was adherent to the chest wall, was perforated, and the pleural cavities was partly filled with blood. The portion of the bullet which caused the wound was immediately found embedded to the depth of about a quarter of an inch in the wall of the apex of the right ventricle of the heart, its exact position being about three-quarters of an inch above the apex. It had not perforated the cavity. The part of the bullet which had caused the wound was the copper-nickel casing, which had evidently stripped off on striking the target.

1906 February 1906.

THE INCREASED MORTALITY FROM "FEVERS" IN THE TOWN OF MADRAS.

THE SANITARY COMMISSIONER'S EXPLANATION.

(Continued from page 107, Vol. XIV.)

In our last issue we gave our reasons for differing with the opinion of the Sanitary Commissioner of Madras, that the increased mortality from "fevers" in the town of Madras was caused by fluctuations in the subsoil water level and the consequent "alternate admission and exclusion of air from the soil."

We will now proceed to the consideration of another point of equal, if not of greater, importance.

We have seen that this increased mortality attracted so much attention that the Government of Madras called for an explanation of its cause, presumably with a view to consider what steps it might take to stamp out the disease to which the increased mortality was due.

Now it is obvious that before taking steps to prevent a disease it is necessary to understand its etiology, and it is equally obvious that, before investigating the etiology, it is necessary to know the precise disease with which we are dealing.

Here, however, there is a difficulty; the increased mortality has been from "fevers," true, but what are fevers?

When we come to inquire into this point, we find that it would be easier to say what are not fevers than what are.

The classification of disease amongst the ordinary population of Madras is primitive. We do not say that Madras is peculiar in this respect, nor do we venture to suggest that such a classification has the approval of that august body the University of Madras; but primitive it certainly is.

All diseases are returned and classified under six heads *viz.*, cholera, small-pox, fevers, dysentery and diarrhoea, injuries, and, all other causes; this is simplicity itself, and is probably as much as one can expect in the present state of affairs. Unfortunately this simplicity, so estimable in many ways, leads to endless complications and murky obscurity where the conduct of more etiological investigations is concerned.

We have reliable authority for stating that when on two occasions deaths returned as due to fevers were investigated, in one case, only 33 out of 77 and in the other 41 out of 150 were found to be really due to the cause assigned.

There is here, as everyone must admit, a very large margin for error; and it is evidently a common thing, and as inevitable as unavoidable, where there is no such thing as a correct diagnosis, to return a large number of different diseases as "fevers," which are not fevers of any kind or description.

We have then under this heading of fevers "a medley of various diseases more or less in accordance with pathology and diagnosis, and now it is difficult to pick out

with any certainty the exact disease or diseases, which has or have caused the increase in the mortality?

This is a difficulty which Dr. King himself notices. He says: "I pointed out that the so-called 'fevers' of Madras are not solely of the malarial variety," and again "I have further suggested, when it is possible to register deaths in Madras correctly in accordance with medical nomenclature, I have no doubt that a very great deal of the so-called 'fevers' from which persons die in Madras will be found to be due to malaria."

Dr. King recognizes the difficulty, how does he deal with it? His method, like the classification of diseases in simplicity itself. He cuts the Gordian knot by asserting that malarial fevers are responsible for the increased mortality, or at any rate that they are responsible to such a large extent, that all the other items may be neglected.

Presumably then he gives good and sufficient reasons for this course! On the contrary, he gives us no reasons at all, unless the following somewhat unnecessary proof of the existence of malarial fevers in Madras has a claim to this distinction. "Lately," he tells us, "39 cases of indubitable local origin and presenting symptoms of malarial fever were systematically investigated with the result of his (Surgeon-Lieutenant-Colonel Graham) demonstrating in each instance the *plasmodium malarie* (the Italian are his). This fact suffices to prove that true malaria exists in the city."

This proof we could have done very well without, for the fact has, we believe, been long past dispute. What we want is some proof that malarial fevers are responsible for the increase in the mortality, and we cannot keep thinking that Dr. King jumped so readily to the conclusion that malaria was to blame in order, that he might air his views on the subject which we will notice later on.

In an inquiry of this kind, we hold that it is the first and most obvious duty of the enquirer to ascertain the exact disease which is in fault, and to produce in his report evidence in support of the selection he has made; and that if he omits to do this, his subsequent conclusions, based as they are upon unknown premises, must appear to the reader void and useless.

Dr. King has not done this. He has acknowledged the difficulty, but he has avoided it. He has constructed a curve showing the monthly mortality caused by a mixed and unknown numbers of diseases, differing amongst themselves to an unknown extent. He has then compared this curve, with a curve showing the level of the sub-soil water, and has pointed to an imaginary connection between the two, and on this he has based the explanation he has given to the Government of Madras.

A more illogical or unconscionable procedure could not well be imagined.

As we have said before, he considers malarial fevers to be the cause of the increased mortality. No one will deny that these fevers are prevalent in Madras, but many, may with good reason, doubt their giving rise to an excessive mortality: in fact a scrutiny of the returns for the five years, 1881 to 1885, shows that their mortality was only 0.76 per 1,000 amongst the prisoners in the Madras Penitentiary, and 1.02 per 1,000 amongst

the Native Troops stationed in Madras; the corresponding admission-rate was 201 per 1,000 and 100-5 per 1,000.

Amongst the Native troops, then, there were 100 admissions and one death per 1,000; at the same mortality rate to give a death-rate of 15 per 1,000 (as it was in 1892 among the general population) there would have to be 1,500 admissions per 1,000.

Thus to produce the number of deaths that were registered in 1892. Every inhabitant of the town of Madras must have had an attack and a half of malarial fever, or every two of the population must have had three attacks between them, which is incredible.

Of course the mortality rate might be higher amongst the general population than it is amongst the troops, as that of the troops is higher than that of the jail population, but if so, we would like to know to what cause it is attributed.

Not at all satisfied that malarial fevers are so much in fault as Dr. KING maintains, and not finding anything in his Report to convince us, we turn once more to his own diagram J, which is very useful and comprehensive.

We now observe a very curious and very remarkable thing; it is this: the curves showing the monthly mortality from malarial fevers, which are fairly regular throughout the ten years of the first or low fever period, undergo a complete change of type in the six years of the second or high fever period.

Throughout the first period the fever curve has, with marked regularity, its maximum in either January or December, except in the case of 1885 and 1887, when there was a slight variation; the maximum in the former being in August and of the latter in July; in 1885 there was also a January and December rise; these were absent in 1887. The year 1887 therefore was the only year in which the January and December rise was not present.

When we come to the second period, we find a totally different aspect of affairs; here the January and December rises are conspicuous by their absence; while we have the maximum, and a very marked maximum it is, in August in 1892 and 1893; in October in 1891 and 1894; and in September in 1895 and 1896. The year 1890 is a complete metamorphosis from the old type; in it the minima are in January and December, and there are two well-marked maxima, one in April and the other in September.

Now what is the import of this? Malarial fever is admittedly a seasonal disease, which pursues from year to year a fairly uniform course, and varies but slightly as to the time of its maximum prevalence. This at any rate is what is observed in most places. Is Madras exceptional in this respect? And if it is, will Dr. KING kindly explain to us the reason?

Out of this another question arises, if malarial fever has altered its time of prevalence amongst the general population. We might naturally expect the same thing to happen amongst the other inhabitants of Madras, has this occurred?

Now in Madras there are three different bodies of men whose statistics are reliable. We have thus ready to hand a sort of control experiment, these bodies are the European and Native troops and the prisoners in the Penitentiary. Has their fever season altered in the same way?

In order to test this, we have constructed the following diagram, which shows the monthly admissions per 1,000 for malarial fevers amongst European and Native troops, side by side with the mortality curves taken from Dr. KING's Report for the years 1888 to 1892, inclusive:—

The diagram shows that the marked change in character, which may be noticed in Dr. KING's mortality curves from 1890 onwards, has no counterpart in the curves which represent the incidence of malarial fever amongst the European and Native troops.

From 1890 onwards the mortality of the general population has its maximum in the latter half of the year, in marked contrast to the curves for the troops, where the incidence throughout tends to accumulate in the first half of the year.

There is a striking difference in the mortality curve from 1890 inclusive, no such difference occurs amongst the troops.

Are we justified in drawing the conclusion that the increased mortality amongst the general population in the second period was coincident with some disease-causing influence which affected the general population, while the troops were exempt from it? There is certainly some reason for the assumption.

This malevolent influence, according to Dr. KING, was sub-soil water fluctuation, etc., but it is hardly possible that it could affect one portion of the population and spare another.

Our own observations pointed to the coincidence between a low sub-soil water and a high mortality from "fever," and Dr. KING contends that a high sub-soil water is healthy in Madras; now in order to substantiate the important rôle that has been attributed to the sub-soil water, it is necessary to prove that the troops had a high one, while the general population had a low one.

If it can be proved that the places where the troops are stationed suffered neither from sub soil water fluctuations nor from a lowering of the sub-soil water level, well and good; but if not, the case against the sub-soil water breaks down.

And indeed everything appears to point to the fact that if a satisfactory explanation is to be given, something more than sub-soil water fluctuations, etc., must be found.

The interest of the diagram we have been discussing is however not exhausted, it is ready to give us some further information. We have mentioned that the highest mortality from fevers was attained in the year 1891 and 1892; the diagram shows us that there was no corresponding increase in the admission for malarial fever amongst the troops. In fact they were actually less during these two years than in any of the others.

This again is contrary to Dr. KING's opinion that there was a great increase in malarial diseases in Madras, and to sift this question further, the question if there is any evidence to show that there was actually a great increase in malarial fevers in the second period, we have constructed the following table showing the admissions for malarial fevers, and for all causes per 1,000 amongst the Native troops and amongst the jail population; the average annual strength of the former being about 1,500 and of the latter about 800.

TABLE I.

Showing the admissions per 1,000 for Malarial Fevers and for all causes, amongst Native Troops and Jail Population in Madras Town, for sixteen years, 1890 to 1895.

Year	NATIVE TROOPS.		JAIL POPULATION.		Year	NATIVE TROOPS.		JAIL POPULATION.	
	Admissions per 1,000 for malarial fever.	Average annual strength.	Admissions per 1,000 for all diseases.	Average annual strength.		Admissions per 1,000 for malarial fever.	Average annual strength.	Admissions per 1,000 for all diseases.	Average annual strength.
1890	609.1	18700	180.8	800.0	1890	180.0	700.0	147.1	841.9
1891	504.9	13289	119.8	538.1	1891	89.0	509.9	197.7	832.4
1892	146.9	7397	146.4	649.0	1892	180.8	689.8	89.6	500.4
1893	154.8	6798	108.7	707.4	1893	61.9	489.7	87.2	679.1
1894	110.7	604.0	48.8	617.4	1894	189.3	477.4	137.2	708.8
1895	76.8	489.0	71.7	840.0	1895	44.7	389.9	176.8	979.7
1896	141.2	609.7	121.6	721.6	1896	68.4	367.1	288.7	1870.8
1897	268.8	589.8	184.1	668.4	1896	308.4	589.0	437.4	1189.6

We cannot claim absolute accuracy for this table; owing to alterations from time in the returns and in the nomenclature, it has been difficult to compile, it can only be taken as approximately correct.

Simple continued fevers are included with intermittent and remittent, as malarial throughout in the case of the jail population.

The amount of accuracy obtained is however quite sufficient to establish the fact, that amongst the jail population there was no sudden increase in malarial fevers in 1891, and that in this respect the jail population resembles the European and Native troops.

It is evident then that if there was this great increase in malarial fevers in Madras, it was limited to the general population, but we can find no sufficient evidence that there was.

We have now shown that Dr. KING's explanation, that the increased mortality was "due to conditions of moisture and alternate air admission and inclusion following fluctuation of the sub-soil water" is untenable, and that there is no evidence in support of his contention that malarial fevers were responsible for the increased mortality.

Malarial Theories.

Here we will leave this matter and turn our attention to Dr. KING's malarial beliefs. These are sufficiently varied, and have for foundation the sandy soil of swamps.

Dr. KING believes that the malarial germ is in the soil. "I hold," he says, "that the soil of Madras contains the malarial germ." We have known many men who held the same notion, and we have also heard of men who believed in black magic and astrology, but we have never found any justification for these beliefs.

The germ, according to Dr. KING, is "presumably the plasmodium malarium." Well the plasmodium is a fertile

The first observation is that the pus is not always at the surface, or that even at the time of operation, pus is not always contained in the abscess. It may be found in the more than the fact will be recalled that the pus is found under these conditions in many abscesses of the brick-dust fever. But if the pus is actually contained in the pus stage, abscesses will almost certainly be found on the second or third day, and then, as the discharge diminishes and the pus becomes yellowish, abscesses may be abundant. It thus appears probable that the abscesses occur near the spreading borders of the abscess and not in the older pus in the central part of the abscess. This has been the case in at least four of the seven cases which have come under my own personal observation. I feel sure that if this fact were fully realized and the adequate precautions taken when searching for the abscess, many cases which have been declared free from them would show their presence. When examined in the method described the bodies, which in the ordinary examination are round, show most active movements and the greatest variations in shape. These, then, are easily recognised as the amoebae coli. Owing to the constant movements the size of the amoebae cannot be stated; but some are large, with a diameter of 60μ ; others are smaller, with a diameter of from 25μ to 40μ . Their shape is oval or round in a resting or dead condition, but when actively moving presents great variations. The constant and characteristic feature of these organisms is their capacity for throwing out pseudopodia, it may be in one or in several directions. Under observation a short, thick, blunt-pointed projection appears at the edge of the amoeba which gradually increases in length by a peculiar flowing movement, the amoeba itself becoming proportionately smaller. This pseudopodium has precisely the same structure as the main body of the amoeba. Sometimes it is withdrawn into the body of the amoeba or its extremity may become fixed, and the whole body of the organism merges into the pseudopodium again. One characteristic of this throwing out of processes is the power the amoeba has of enclosing neighbouring cells or particles. One can often see the inclusion of a red corpuscle thus take place.

The structure of the amoeba is difficult to make out clearly owing to its hyaline transparent character. There appears to be a well-defined outer edge, although the organism is really naked mass of protoplasm without a cell membrane. The main body of the amoeba may be divided into two parts: (1) an outer clear investment, the ectosome; and (2) the inner granular looking endosome. In the latter numerous small vacuoles are seen, not of regular size but occasionally one is seen considerably larger than the others; nothing has been seen of the nature of a contracting vacuole, in which manner it differs from the ordinary fresh water amoeba. Situated in the endosome is the large single nucleus, but this cannot be easily seen in living specimens, but in those that have a little rest and will be told the nucleus is bright and distinctly contrasting with the wood or opaque. In nearly every amoeba a variable number

of red corpuscles are seen. There may be as many as fifteen or twenty arranged in various rows and their overlapping edges help to give rise to the peculiar appearance of the endosome. Sometimes dark masses of pigment are seen and the amoebae are sometimes stained yellow with bile.

What was said about the constant contamination of the liver pus when searching for these organisms, holds good in this case; even the contact with a water bed-gon is quite sufficient to kill them, unless they assume a round shape, so that they may be quite easily overlooked. Collins says that this variety of dysentery is often fatal, but not of a dysentery recently under my own observation only one patient has died. COUGHLIN and LAPLEUR have demonstrated the amoeba in the liver of the sheep, in the rat, mouse, and deeper layers of the intestinal wall and also in the lymphatic vessels. The pus from a true tropical abscess usually shows a complete absence of pyogenic organisms. And examination of the pus failed to show any pyogenic organisms. Collins supports the opinion, based upon COUGHLIN and LAPLEUR's experiments—that the pus of "tropical abscess" (connected with dysentery) is quite free from pyogenic bacteria. On the other hand, MACFADYEN holds that in tropical abscesses pyogenic organisms are constantly met with, staphylococcus pyogenes aureus being the commonest, while the staphylococcus albus and streptococcus pyogenes are often found.

This point about the sterility of tropical abscesses is most important. If it can be clearly proved that infective organisms are constantly present and are the essential cause of the suppuration, then there will be little reason for differentiating a special class of abscess of liver; that is to say, all hepatic abscesses will be of an infective nature and the only features specially characteristic of the tropical abscess would be its occurrence most frequently in the tropics, its tendency to be single, and finally a curious connection with dysentery. This latter connection would be quite easily explained by the entrance of the infective organisms from the lesions in the large intestine into the lymphatic or portal radicles and which would so be carried to the liver. On the other hand, if we admit the conclusions of COUGHLIN and LAPLEUR, supported somewhat by observations of our own cases, as being substantially accurate, the pyogenic character of the abscess would be disproved and it would be necessary to find some other cause for the production of tropical abscess.

We have here a clear and intelligible explanation of a much disputed point, the etiology of tropical liver abscess, which only requires to be more widely confirmed.

India offers a wide field for research of this kind, and we hope soon to have an opportunity of recording the results obtained by Indian investigators of this subject.

There are three important questions to which answers are required: (1) Does this amoeba form of dysentery prevail in India? (2) Does tropical abscess ever occur in its absence? (3) Is the pus of a tropical liver abscess always sterile?

The answers to these questions are well within the reach of hundreds of workers, and for the credit of medical science in India they ought not to remain long without a solution.

THE LIFE AND TIMES OF THOMAS WAKLEY, FOUNDER OF THE LANCET.

III.

By the end of 1825 the *Lancet* was a recognised publication of more than two years' standing with a regular circulation of upwards of 4000, and a well-defined policy and range; in its contents, however, two alterations were noticeable; the first was that all matter not strictly medical was excluded; the second an unmistakable tone of hostility towards the hospital officials.

The disappearance from the paper of the weekly columns entitled respectively "The Chess-Table," "The Dramatic Lancet" and "Table Talk" meant more to the Editor than their importance would seem to warrant.

It was the sacrifice of his own hobbies to the pressure of what he conceived to be his wholly absorbing duty. WAKLEY was a great chess-player, and an enthusiastic play-goer. He was one of the few who contested successfully with the original and celebrated automaton player, and it was his custom, when engaged in editing his paper, to have a chess board by his side, on which at leisure intervals he would set himself problems.

The *Lancet* was the first paper to inaugurate the now common custom of publishing chess problems and games. WAKLEY believed that the study of chess was a recreation peculiarly fitted to the mind of the properly trained medical man, and might almost be said to form a factor in the ideal medical education; it is interesting to note that he refers to Sir ASTLEY COOPER as possessing a considerable degree of excellence in this scientific game.

The second alteration was, however, of more importance. Here his intuition and foresight told him that unless he declared absolute and unrelenting war upon those who were attempting to restrict his operations for reform, he would fail utterly and hopelessly.

The war began in the department of the paper that is now known as "A Mirror of Hospital Practice;" the former title which was in use for twenty-six years was "Hospital Reports."

Throughout the first volume the reports were, on the whole, eulogistic, and no word derogatory to the operator ever appeared, while censures were passed upon the conduct of the students, and the necessity of attention and respect to their teacher was urged on them.

The preface to the second volume, however, stirred apprehension; for WAKLEY in it insinuated that the hospital surgeons might have awkward matters to conceal, which it would be his duty to reveal.

Certain hospital abuses were found fault with. Here is one which sheds a light upon hospital management in these days:—

"We understand that persons were allowed to vend porter in the wards of St. Thomas' Hospital and to hawk oranges, tarts, etc., through those of Guy's."

What brought matters to a crisis was the report of a lecture by Sir ASTLEY COOPER in which he inveighed strongly against the prevailing abuse of mercury. "I do say," he said, "that the present treatment of patients

in these hospitals, by putting them unnecessarily under a course of mercury for five or six weeks, is infamous and disgraceful."

Immediately after the publication of this in the *Lancet*, meetings were held and new regulations were come to on the subject of treatment. WAKLEY was naturally jubilant that publication in his paper had brought about this reform; he did not conceal it, and Sir ASTLEY COOPER thought it necessary to state that in his plain-speaking he had not been actuated by any desire to injure the surgeons of the Borough Hospital "who are the men, gentlemen," he said, "against whom it has been supposed that these observations were directed? Are they men whom I could possibly feel disposed to injure? Mr. TRAVERS was my apprentice, Mr. GANN is my godson, Mr. TYRRELL is my nephew, Mr. KEY is my nephew, Mr. MORGAN was my apprentice."

Here was a chance for WAKLEY. He rallied Sir ASTLEY COOPER on the nepotism thus naively revealed, professing himself to be convinced that it was impossible that he could be actuated by other than friendly feelings towards such a family party.

That same day, May 2nd 1824, WAKLEY was excluded from attendance at St. Thomas' Hospital by order of the surgeons of the institution. He continued his hospital reports however, still visited the wards and operating room when inclined, and defied the surgeons to prevent him obtaining whatever information he desired.

What had happened did not tend to amicable relations between WAKLEY and the surgeons of St. Thomas' Hospital, Messrs. TRAVERS, TYRRELL and GANN, who had signed the order for his expulsion, he contemptuously called Ninny-hammers, a nickname hallowed by Sterne, Swift and Arbuthnot, and their proceedings were alluded to in scathing articles under the head of "Hole-and-Corner Surgery."

These articles derived much of their interest and point from the unfortunate interference of Dr. JAMES JOHNSON, at that time Editor of the *Medico-Chirurgical Review*, who sided with the surgeons and argued that "No man can command success in surgical operations, and if a surgeon fail from want of dexterity, he suffers mortification enough heaven knows! in the operation room without being put to the cruel and demoniacal torture of seeing the failure blazoned forth to the public." The remarks of this paper furnished WAKLEY with exactly the kind of object he most relished attacking—a narrow view held by monopolists or their advocates. He combated them with a savage relish of the task, laughing at them and rending them alternately. "This latter," said he, referring to the above quotation, "is so monstrous a proposition that, prepared as we were for the imbecilities of the Hole-and-Corner Champions, we were somewhat staggered at the impudent absurdity with which it is advanced..... Not a scientific of compassion does the Hole-and-Corner advocate so as to escape him for the victim of the surgeon's want of dexterity; all his sympathy is reserved for the ignorant operator."

The preface to the volume of the *Lancet* published in October 9th, 1824, contained a very serious reflection upon Mr. TYRRELL, which led to an action for libel.

Mr. TYRRELL, published review of the whole of Mr. ASTLEY COOPER'S lectures, with illustrative cases from his own hospital practice appended.

These lectures, WAKLEY said, were transcribed, errors and all verbatim from the *Lancet* and no acknowledgment given of the source.

The article exposing TYRRELL was entitled "The Real Simon Pure," and accused him in unmeasured terms of literary and professional incompetency, asserting that the text of Mr. ASTLEY COOPER'S lectures had been bodily stolen from the *Lancet*, and that the illustrative cases were badly chosen and unimportant as a whole, and that one in particular had been seriously garbled, being recorded as a success in spite of the fact that it had a fatal termination.

Terribly relentless and almost savage as this article was as an indictment, it was a masterly piece of work, and it is impossible to read it now without feeling that the pen that wrote it was moving in obedience to a mind not stirred by petty malice, but fiercely awayed by passionate conviction.

In the trial that followed, WAKLEY was represented by Mr. BROUGHAM (afterwards Lord BROUGHAM) whose defence in this case was one of his finest forensic efforts, damages were laid at £2,000, the verdict was for the plaintiff, damages £50.

This was chiefly due to the summoning up of Lord Chief Justice BAKER, which is considered unfair.

Immediately after the trial WAKLEY, with characteristic decision, or obstinacy, or audacity, published his opinion of the proceedings, and took occasion to recapitulate every word he had uttered previously and for using which he had just been fined. He virtually charged the Lord Chief Justice with taking up the cudgels in Mr. TYRRELL'S behalf against the *Lancet*, and accused him of acting unfairly.

THE TYPHOID BACILLUS IN WATER.

We quote from the *Public Health Engineer*—"Dr. WASHBURN, bacteriologist of Guy's Hospital, who has just concluded his examination of the Maidstone water-supply in connection with the recent epidemic of typhoid fever, makes the following interesting remarks:—"The difficulties of discovering the typhoid bacillus in drinking water are so great that it is still a debatable question whether they have ever been surmounted. It is a debatable question whether it is possible in the present state of our knowledge to discover the presence of the typhoid bacillus in water contaminated with animal material. Most of the cases in which typhoid bacilli are stated to have been found in drinking-water, occurred at a time when tests available for distinguishing the typhoid bacillus from other bacteria were insufficient. The source of contamination of water with typhoid material is probably always the excreta of patients suffering from typhoid fever. Such water would contain large numbers of coli bacilli in addition to much smaller numbers of typhoid bacilli. The difficulty, if not impossibility, of recognising the typhoid bacillus in these circumstances is so great, that no importance can be attached to the failure of discovering the typhoid bacillus in water suspected of being the cause of an epidemic of typhoid fever."

COMMENTS AND NEWS.

SUB-SOIL AND DISEASE IN BOMBAY.

No doubt many learned explanations will be forthcoming to account for the second epidemic of plague in Bombay, and we may expect many far-reaching hypotheses, vain speculations and much talk about bacilli and other fads of modern learning.

"Learning, that cobweb of the brain
Effects, erroneous and vain."

Whatever the result may be, to outside observers it must be fairly evident that in spite of all the prognostics that have been taken, and all the efforts that have been made, there is some weak point, some plague spot we may say, which has as yet been untouched.

The difficulty of eradicating the plague from Bombay has been proved. Therefore we conclude that in Bombay city there is some condition that is fundamentally suitable to it, that it regards Bombay as a highly desirable, permanent residence.

We would ask if this condition, this special attraction, has anything to do with the state of the sub-soil, and this is a practical point.

We have before alluded to the water-logged state of the sub-soil and expressed the opinion that no real improvement in the health of the city can be expected until this was remedied. Our contemporary, the *Times of India* draws attention to the matter in a forcible article, (22nd January), the sentiments of which we can most cordially endorse.

The sub-soil of Bombay city we find described as "a marsh of stagnant water."

We read that in the last eleven years the level of the sub-soil water has risen eight feet, from twelve feet below the surface to four feet; over three quarters of an inch a year.

We stand aghast at such a state of affairs, and find ourselves wondering if the authorities who are responsible for it are deaf and blind, or in their last dotage, or whether they are all undertakers and have an interest in consigning their fellow citizens to the dust.

How much longer, we wonder, will these supine figure heads stand passively by, looking on at the rising tide, perhaps until the city is decimated, or until they see the water splashed up by their carriage wheels,—but out of sight out of mind.

In a Report to the Corporation in September last upon this subject, Mr. SNOW, the Municipal Commissioner, wrote: "Measures for the rapid removal of such water are most urgently needed;" and again he says further on, "I wish specially to press upon the attention of the Corporation the urgency of this matter, as it is a generally acknowledged fact that the present condition of the Tardeo Flats is a standing menace to the health of the city, not only are the natural escapes for sub-soil water blocked and its level raised in all the adjacent parts of the city, but with the continuous back flow of water polluted by contact with and seepage through disintegrating kutcha, a grave source of danger and infection to several hundred thousands of the population is constantly present."

Such is the warning, one of many, given last September, a scheme of drainage has been drawn up and approved, and stated by competent authority to be well within the resources of the Corporation, but still they pause, do they think this slow and steady rise of water in the sub-soil a thing to be played with, that this enemy will delay its stealthy approach to suit the convenience of their tardy Councils?

The Bombay Corporation cannot plead ignorance of the fact, it is notorious, they can only prove their ignorance of

the city, and the water supply, but took no steps for its removal, a conspicuous display of sanitary ignorance, the natural result is that what was supposed to have been a blessing has proved to be a curse, the water keeps soaking into and saturating the sub-soil; there is an enormous waste which they do not hesitate to check by means.

Such neglect, such ineptitude is criminal. How long, how long, will it be allowed to continue! This Corporation has undergone a fatty degeneration from an over-indulgence of self-indulgence and subsequent slothful repose, it requires purging and the Government will have to be called in to administer its most drastic remedies; otherwise one of the finest cities in India is doomed.

It is well pointed out that the new Government scheme for a regenerated Bombay, which chiefly consists in the construction of new and wider thoroughfares and better house accommodation, is foredoomed to failure, a beautiful, well laid out city resting on a "sloUGH of despond" all above fair, all below beastly; like to a marmalade.

This design will not restore Bombay to its pristine state, it will not restore the blessing of health to the lovely city

"It will but skin and flim the ulcerous place,

While rank corruption mingles all within "infects unseen."

As long as this state of affairs affected Bombay alone, outsiders could afford to regard it with equanimity, their affairs were no concern of ours, they probably knew best what was good for them, at the worst it was only another conspicuous example to be added to the long roll of incapable Bumbeldom, and as they made their bed, so must they lie on it. But now that Bombay has become a source of danger and menace to the whole of India, things are changed. We don't want within our boundaries a place specially suitable to be a breeding place for, and a disseminator of plague to the whole country.

In the history of the Plague the record of Bombay is not one to be proud of, and if they cannot see to the matter themselves and cleanse the Augean stable, it is quite time that a higher authority stepped in and did it for them.

GOVERNMENT DOCTORS AND PRIVATE PRACTICE.

SIR ALEXANDER MACKENNIS, the Lieutenant-Governor of Bengal, in his public address at the laying of the foundation stone of the new European General Hospital in Calcutta, said that the Superintendent who would succeed Dr. CROMBIE, the present incumbent, should not be allowed private practice, and that he should reside in or near the hospital grounds in order that he might be present whenever needed, and to see that his orders were carried out. This is the first instalment of a death blow to the illegal and dishonest system on the part of the State, in allowing State-paid doctors to engage in private practice. Among the "military" staff of "general practitioners" who officer our public hospitals and do family practice in all their spare time, it must be admitted that there are some who realise that their official duties are sufficiently onerous to demand their giving up family practice, and to resort only to "casual calls" and "consultative work." One notable and praiseworthy instance of an official doctor with a conscience, is the Principal of the Calcutta Medical College, who, though he is likely to be "one of the most requisitioned of consulting physicians," flatly refuses to do "private work of any kind;" as the doing of it interferes with the efficient performance of his State duties. We have heard it occasionally from more than one Government doctor in Calcutta, that the Government could not do a wiser or better thing

for the Medical College than to absorb the students and even for the doctors themselves to take their education in the wild rush after private practice, thus to deprive all officials in the I. M. S. in Calcutta, Madras and Bombay, from engaging in general practice, and to withdraw them to devote their leisure time to purely consultative work. The absurdity of the whole system may be seen by considering any single appointment at the Calcutta Medical College. One officer, for example, has the entire charge of one of the largest women's hospitals in the world. He spends one hour or less sometimes, though rarely more, in the wards of the hospital. On Sunday he does not visit the wards at all. He has a large practice as a family physician; he is secretary to an educational institution; he is private physician to over a dozen commercial houses in the city; he is medical adviser to some insurance offices, he is a Presidency Surgeon and ought to attend Government servants residing in Calcutta; he is a Professor of Midwifery, having the training of a few hundred medical students and a few dozen European and native midwives under his care. How in the name of conscience can any man perform efficiently such a plurality of offices? How can students learn anything, either from the lectures or the clinical teaching in the wards, from such an overburdened and care-worn official? The mere enumeration of such labors and cares ought to drive home to the mind and conscience of Government, that work under such conditions and circumstances must be done in a most slipshod and irregular fashion, and that an honest administration would abolish such a system of reckless incompetency, root and branch, at a single blow. But the Medical Administration of the Supreme and Provincial Governments is devoid of that element of boldness and fearlessness that seeks to eradicate evils of old growth, even though rank dishonesty stares out at every nook and corner of a rotten and disgraceful system of providing for the medical and educational needs of India. Of course this tottering edifice of Indian Medical Service monopoly, and the gross mismanagement of our public hospitals and of our educational institutes of medicine, cannot stand out very much longer. One by one the "plums" are disappearing, one by one abuses are being set aside, and certainly within a few brief years, public opinion will cause a shaking off of the accustomed stupor and indifference from the official conscience, and these extremely crooked paths will be made straight. For the present, however, until reforms are brought about, the Director-General of the Indian Medical Service and every Inspector-General of Civil Hospitals, has a serious charge to answer, in permitting the evils complained of to exist. It is because these officers fail to do their honest duty that these abuses do exist. And yet they accept their huge salaries for "doing their duty!"

THOUGHTS ABOUT DR. BENNETT HART'S LIFE.

We quote from *The Lancet* with regard to Mr. BENNETT HART's personal character and the aims and motives by which he was actuated, we cannot do better perhaps than quote the words spoken by a close and sympathetic friend, the Rev. CANNON BARNETT, at the memorial service held on 11th January at Marylebone Parish Church. In the course of his address CANNON BARNETT said: "Much of us is thinking of some aspect of BENNETT HART's character which drew our admiration or affection. One remembers the ardent intellect which burnt up difficulties, another the masterly ordering of facts; for some he is the keen fighter who fought for his side with sharpest weapons; one will think of the strong critical power which dissected and tore to shreds worn-out traditions; another will think of the love of beauty which so enriched his home, his garden, and his talk, and made him so anxious to increase the open spaces of London."

A fissured tongue points to the kidneys, either an inflammation or something wrong with secretion.

Yellow coatings are usually associated with morbid liver and want of biliary secretions, and would indicate mild hepatic and tonic.

Raised papillae, bright red, denote irritation of ganglionic nerves and irritation of stomach, especially the mucous coating. Shows exhaustion; no digestion, and needs rest; use vomica twenty drops, and the food to be warm, and taken in small quantities. Bismuth and pepsin after food.

Broad thick tongue, papillae not visible, but looking raw, denotes a septic condition of blood, and favors typhoid fever. Indicates, if deep red, sulphuric acid; if pale, sulphite soda. Liquid food, sipped warm, in small quantities.

Deep, dark red tongue and dark coating, indicates septic condition of blood.

Shades of dark brown and black denote typhoid condition, or septic conditions.

Pale, dirty fur on tongue denotes acidity, and a septic condition of system; indicates sulphite of soda; but if membranes are deep red, sulphuric acid will be admissible, because it would show an alkaline condition of blood.

Contracted, pointed, cannot hold still, and drawn to one side of mouth, denotes a wrong with the nerves, and perhaps the brain. Requires great care and study of condition.

Dry tongue always denotes feverishness or inflammatory condition, a wrong with the nerve centers of ganglia.

Thick tongue, and curved edges upward, denotes atony of the nerve centers of ganglia, requiring stimulants, nuxvomica or strychnia, and quinine.

Pointed narrow tongue is the tongue of sluggish condition of digestion and assimilation, and congestion, especially of the base of brain. Restlessness and constant change of position is usually present.

Milk diet, warm, and in small quantities. Pepsin after. Calomel one-tenth grain, and one grain of soda every three hours, and quinine two grains every three hours.

THE LIFE OF SIR JAMES RANALD MARTIN C.B., F.R.S. BY SIR JOSEPH FAYRE, BART.

SURGEON-GENERAL SIR JOSEPH FAYRE, Bart, has conferred one more obligation upon us by his recently published life of Inspector-General Sir JAMES RANALD MARTIN, C.B., F.R.S.

The name of RANALD MARTIN is well known to all students of Indian or of Tropical medicine, and a perusal of his life cannot fail to be interesting. He has taken a chief place as a pioneer of preventive medicine in India, and also asserted a right to a prominent position among the promoters of sanitary reform in England. He devoted a long life with conspicuous ability, diligence and tenacity of purpose to the saving of human life by means of the ameliorating of those conditions which give rise to fatal illness.

For ten years Calcutta was his place of residence. During these ten years he was constantly engaged in schemes and projects, having for their object the improvement of the health of troops, prisoners, and the population at large.

He devised new forms of statistical record, designed to display more clearly the influences affecting health and longevity. He initiated an important scheme of medico-topographical surveys and reports intended to shed light on the causation of disease. He promoted and aided in conducting a searching inquiry regarding the health and sanitation of Calcutta, and started that sanitary movement of which the capital city stood in such urgent need, and

which is still in progress, and still far from being as real and effective as it ought to be.

He was one of the main founders of the Calcutta Hospital and Medical School.

He recommended the location of British soldiers in the hills during the hot weather. He strove to raise and benefit his own service, and he succeeded in obtaining for them improved pensions and a share of the honours and rewards distributed for good service. He explained to urge the claims of the medical services to equal rank and reward with their combatant brother officers as long as he lived.

In this he was at one with the ablest and greatest of Indian Administrators, the Marquis of Dalhousie, who in a long minute contended that "the medical officer in respect of real rank, dress, honours, and promotion should be placed on a footing with his brother officers."

After a busy and active life, full of honours and dignities, he died in England at the age of 79.

GOVERNMENT METHODS IN DEALING WITH FAMINE AND PLAGUE.

UNDER the heading "Famine and Plague in India," the *British Medical Journal* makes the following very just remarks, the truth and aptness of which will be almost universally recognised in this country:—

"The famine threatened twelve months ago to be the greatest calamity, but it has been tided over with a marvellous success. There can be no question as to the brilliancy and effectiveness of the measures taken to combat the danger and to distribute food to the famished millions. Guided by officers experienced in this special work, the Government of India has been able to carry out schemes of relief which have never been equalled in magnitude by any other Government in the world, or by any previous effort on the part of the Indian Government. The number saved from starvation is enormous.

"This success has been mainly secured by acting on the principle that officers trained in the methods of dealing with famine were the best to organise and conduct famine operations. It is a principle which is also and rightly followed in the case of war. In the war against the rebellious tribes on the North-West Frontier the best officers in the Indian army were sent to conduct the campaign. The principle is here recognised that those who are trained to the work know best how to direct and conduct it. This is common sense.

"It is, therefore, a matter of surprise that a similar policy was not accepted and adopted in the fight against plague. The prevention and checking of the spread of plague are essentially medical questions, and it was to have been expected that the medical profession would have in this instance been given positions of prominence and trust. But this has not been so. Trained medical men, as the controlling agency, have been conspicuous by their absence. Their part has been a secondary one, while military and civil officers have played the prominent part in direction and control, and have been appointed to positions for which they are not specially fitted either by knowledge or training. This is not in accordance with common sense.

"It is a curious spectacle, this reversal of the ordinary conditions of life—the untrained trying to command and lead the trained. If a similar policy had been adopted against plague as was wisely observed in the famine and the frontier war, there can be little doubt that a similar success would have attended the efforts of Government, and there would have been no occasion to deplore the enormous loss of life which is now taking place in the Bombay Presidency."

FAMINE AND PLAGUE IN INDIA.

BREDAVE-SURGEON-LIEUTENANT-COLONEL C. W. MACRUX, I.M.S., writes to the *British Medical Journal* as follows:—"With reference to the leading article on famine and plague in India in the *British Medical Journal* of 8th January, your readers will hardly be surprised to learn that a civilian with the rank and title of "Plague Commissioner" has been appointed by the Bombay Government. This officer has recently been acting as Commissioner in Sind, and having to vacate this appointment on the return of the permanent incumbent, this post was specially created for him, in which he draws a handsome salary and allowance for controlling and directing the specially selected medical officers lately sent out from home by the India Office, and he will no doubt in due course be credited with, and decorated for, the results of their arduous labors.

"This proceeding is as incongruous as the policy hitherto observed of entrusting all power in regard to plague operations in the districts to assistant collectors. I have known a collector to be so jealous of his authority as to insist on inspecting vaccinators' registers and office records for fear he should not be considered paramount in his district. It seems that the severe lessons it is now experiencing does not convince the Government of the preposterous absurdity of placing trained experts under the orders of amateurs, however high in the grade of Civil Servants. It clearly proves—if proof were needed—the official estimate of sanitation, and indicates how essentially necessary it is for the welfare of India that the sanitary department should be more than a mere name, which has hitherto been its fate. A long and bitter experience has convinced me that no real progress or reform in sanitation can be effected until the Government of India takes the matter directly into its own hands.

UNFOUNDED STATEMENTS ABOUT PLAGUE INOCULATIONS.

It is a pity for Dr. KHAJA ABDULLA, of the Mahomed-bhay Ebrahim Khoja Hospital, and also for those whom he may have most unwarrantably mislead, that he did not exercise great care to ascertain the accuracy of his facts before rushing into print to cast discredit upon the efforts of Dr. HAFKIN'S plague inoculations.

His statement was that six inoculated persons were under treatment for plague in his hospital, and that five of them died.

Dr. HAFKIN in a letter addressed to the *Times of India*, gives the fullest particulars concerning all these six cases, and is able to refute Dr. ABDULLA'S statement in the most satisfactory manner; the letter concludes as follows:—"Thus of the six cases three fatal ones were not inoculated; of the others one fatal was inoculated once 8½ months before; another was attacked on the day of inoculation, before the inoculation could have exercised any effect; and the third, attacked 10 days after inoculation, made a very speedy recovery.

"Although, therefore, Dr. ABDULLA'S information admitted of some correction, I hope neither he, nor anyone else, will be discouraged by that from keeping us early informed of any cases of plague they may come across among the inoculated. There will be no harm in the information being approximate, or incomplete, or even inaccurate, as we are in possession of all the necessary data for control and verification."

HOME SEGREGATION FOR PLAGUE.

THE question of home segregation has again been brought prominently forward in a contemporary medical journal. This system was strongly urged on the attention of Govern-

ment by the Indian Medical Association, as recorded in the *Indian Medical Record*, 1st April 1907, and it is difficult to see what valid objections can be urged against it.

Setting altogether aside the religious and caste prejudices of the Native community, though they are by no means a negligible quantity, it is certainly the course that would be followed in European countries. In India its acceptance is all the more imperative, considering the utterly inadequate nature of the hospital accommodation. It is the first duty of the authorities, casting forth people from their homes, to provide suitable accommodation for them.

Besides what can be more logically satisfactory from a sanitary point of view than that the affected person should be segregated in the very place where the disease was contracted, and the whole of that place, i.e., the infected house, quarantined, in this way all the risks inseparable from the conveyance of infected persons through the streets is avoided. The house is marked, it is quarantined, and subsequently thoroughly disinfected.

DR. ERNEST HART ON SANITARY REFORM IN INDIA.

BEFORE Mr. HART started for India to attend the Medical Congress at Calcutta, he had prepared a laborious and lengthy speech on the sanitary needs of India, which had been put into type before he left England. Finding it was much too long to give as a spoken address, he, on arrival at Calcutta, engaged the services of a shorthand writer, dictated to him a summary of this address, which was accordingly furnished to the press as his intended speech. When, however, Mr. HART stood up to address his audience all notes were discarded, and brimful of his mission he delivered one of the most brilliant philippics ever heard on such a subject, sparkling with satire, trenchant with indisputable facts, and dealing straight blows at those in authority for supineness and neglect. He held his audience spell-bound, short bursts of laughter which greeted his sallies of satirical humour breaking only the silence with which he was listened to and his close arguments followed. Deriding the printed recommendations for the prevention and staying of cholera among troops, he held up in his hand the Blue Book in which the medical officers were recommended to march the troops out of the barracks at right angles to the wind, and exclaimed, "You might as well tell them to walk."

This speech and Dr. HART'S subsequent open letter to the Viceroy had a profound influence in inaugurating sanitary reform, although the hard hits of attack aroused a good deal of sore feeling and useless recrimination at the time.

RELAPSING FEVER IN BOMBAY. DEFECTIVE RETURNS.

THE *Times of India* says:—"It is notorious that relapsing fever has been prevailing for some weeks past in an epidemic form, causing a mortality of from 8 to 12 per cent. of the persons attacked, and yet this fatal epidemic is unnoticed in the returns. The existence of the disease appears to be ignored by the death registrars: certainly it finds no place amongst the causes of deaths. As a matter of fact, one contagious diseases hospital in Bombay has upwards of one hundred beds occupied by cases of relapsing fever which have been carefully diagnosed. The Plague Committee take cognisance of such cases and remove them to hospital as soon as detected, but official record takes no notice of them, for if any of these cases, which are carefully examined in the hospital, prove fatal, the presumption is that the Medical Officer, who fills in the return, records the cause of death as relapsing fever. If this presumption is correct, it

follows that all such deaths are registered under a wrong and a misleading head. It is highly undesirable that such a very contagious and widespread disease, as scurvy fever is known to be, should be disregarded in registration. It may hardly become a serious sanitary question whether a large plague hospital is the most desirable place for the treatment of scurvy fever."

NEW YEAR RESOLUTIONS.

THE *Public Health Engineer*, an excellently conducted journal from which we derive much useful information, publishes the following amongst other pithy comments under the above heading:—

"We are informed upon untrustworthy authority that the undermentioned bodies have passed the following good resolutions for the New Year:—

"The Corporations of Provincial Towns: 'To follow out the recommendations of their technical advisers, their medical officers of health, engineers, and surveyors, and to abstain from blaming them for the consequences brought upon the towns by not carrying out said recommendations.'

"The Water Analysts: 'To try to catch a typhoid bacillus, and to learn something about his habits, customs, and methods of infecting the human family.'

"The Medical Officers of Health: 'To endeavour to look upon sanitary engineers with toleration.'

"The Sanitary Engineers: 'To try to bring themselves into a frame of mind which will admit of their acknowledging that all medical officers of health are not hopelessly ignorant.'

"The Government of India: 'To realize that prevention is better than cure, and to introduce some sanitary measures in India.'"

DIRTY BARBERS' SHOPS.

DR SUITER, in "Society Reports" makes the following remarks on the dangers of the barber's shop:—

"There is scarcely a step in the processes usually employed by the barber to-day which does not carry an element of danger when the most careful precautions are not observed. It is remarkable that the first steps toward antiseptic methods in this trade were introduced only last month at Paris. There metal combs and brushes are required, and they, with the razor, clippers and scissors, are subjected to heat of 100 degrees centigrade before and after use. Shaving brushes are washed in boiling water. The towels are sterilized, the barber must wash his hands in an antiseptic solution and the hair which is clipped must be removed and destroyed at once.

"The reason why I grew a beard, was that a patient I was treating for an organic disease which had broken out in eruptions on his face had just gotten up from a chair in a barber shop which I frequented. The alum sticks to staunch the flow of blood and the block of magnets for drying the newly-shaved face are used for customer after customer, and should be, like the articles of the trade, made subject to restriction."

A PRESCRIBER'S CLAIM TO HIS PRESCRIPTION.

SAYS the *Chemist & Druggist*:—"The *Lancet* puts forward an untenable claim on behalf of prescription authors. It quotes from the ladies' column of some (unnamed) weekly paper wherein is mentioned a "face massage-cream," which is alleged to prevent or cure wrinkles. The writer says a lady-friend of hers got the prescription from a celebrated doctor in Harley Street eight years ago; that it cured her wrinkles; that she has given the prescription to dozens of her friends, with satisfactory results; that letters about it will be answered;

ed; and that she thinks seriously of putting it on the market. 'But,' says the *Lancet*, 'it is not hers to put.' And comments are made on the blatant dishonesty of the two ladies concerned. The statement that it is 'not hers to put' appears to be simply senseless. Unless the doctor patents his formula or makes an express contract with his patients, he has neither a legal nor a moral right to object to a preparation which he prescribed being used by any number of people. And where the 'blatant dishonesty' comes in passes our understanding. A schoolmaster or lecturer might just as reasonably claim that none of his pupils should use for their own benefit any of the education they obtained at his classes."

THE SURGICAL WORK OF OUR ARMY SURGEONS ON THE INDIAN FRONTIER.

NEVER was the want of the professional incompetency of the British Army Medical Officers more thoroughly and effectually vindicated than in the present war in the North-West Frontier of India. The surgical emergencies of the struggle were immense, and the demands on the operative skill of the Army Medical Staff was equally so. Capital operations of the severest type have been performed by the hundred on the battle-field and in the moveable camps, and so perfect has been the equipment and so harmoniously have the medical units fitted into every emergency, that there has not been a single hitch during the whole campaign. The sick and wounded have been attended to admirably, and the results of the surgical work on the field have been brilliantly successful. Every case of amputation of limbs has proved a success. Not a single septic difficulty has been found in the whole history of the campaign. These facts speak volumes to the credit of our A. M. S. Officers and to their hard-working local staff, the Military Assistant Surgeons. We understand that the great French military medical expert who was deputed to observe and to criticize the working of the British system of military medical equipment in India, and who has seen the whole scheme in active order on the frontier, has pronounced the most favorable opinions on our army medical organisation. It is he says, infinitely superior to anything else in the world. This opinion has been fully endorsed by a Japanese expert also. Unquestionably the Army Medical Staff has fully vindicated its professional honor in such a manner as to silence the hostile and envious criticisms of the authorities at the War Office, who so grudgingly concede the pressing reforms of which this excellent service stands so much in need.

CONSULTING ROOMS AT CHEMISTS' SHOPS.

THE *Chemist and Druggist* says:—"The *Medical Times* having been asked on several occasions to give its opinion as to the advisability of a medical man renting a portion of a chemist's house as consulting rooms, thus expresses itself:—

There can be no doubt that a medical man has the right to rent consulting rooms in the house of a chemist, but anyone wishing to succeed professionally would be well advised to keep as far away from chemists as possible. To be so closely associated would give the public some ground for thinking that a very good understanding existed between them, and the doctor would probably be regarded with suspicion. Medical men, in their business-relations with chemists, should always remember that they have to maintain the honor and dignity of a profession that has been reckoned a 'noble' one.

"Such talk is not, to say the least, calculated to foster that good feeling between medical men and chemists which, in our opinion, should continue to exist."

THE CALCUTTA MEDICAL SCHOOL.

THE Hon. and Mr. Justice TREVELYAN, Vice-Chancellor of the Calcutta University, visited the school on the 2nd of February. He inspected all the departments in connection with the school and the hospital.

Among the students, there were present among others:—
Dr. RAI LAL MADHAB MUKERJEE, Bahadur, Dr. E. G. KISHORE, N. MITTRA, S. M. DAS, N. N. BASU, PRADHUMN BHATT, SARAT CH. BASU, CHAND LAL BASU, RAHMAT ULLAH GHOSH, BHAI MADHAN BHATT, SARDAR PRUSAD GHAKHARANTY, and GODADHAR GHAKHARANTY.

The students of the school lined both sides of the road which led to the entrance, forming the guard of honour.

In the visitors' book, his Lordship expressed his opinion in the following way:—

"I inspected the Calcutta Medical School on the 2nd of this month and was exceedingly pleased with all that I saw. Great credit is due to those who have established and maintained this school. Its work is invaluable. Besides that it affords medical aid to many sick poor in Calcutta, it distributes a large number of qualified medical practitioners in the districts. It is interesting to see how it is possible for the gentlemen of this country to carry on a medical school on European principles but without any European aid. I wish every success to this Institution, and am much obliged to RAI LAL MADHAB MUKERJEE, Bahadur, for the opportunity of seeing it which has been afforded to me."

(Sd.) E. J. TREVELYAN, 4th Feb. 1893.

THE SCANDAL OF EUROPEAN HOSPITALS IN INDIA.

SAYS the *Phoenix*, a leading Indian paper:—"The foundation-stone of the new European hospital was recently laid by the Lieutenant Governor of Bengal in Calcutta, and His Honour distinguished himself by a very happy speech on the occasion. The Government of India have promised ten lakhs of rupees for the scheme and the Bengal Government will pay twelve. Thus twenty-two lakhs of rupees wrung from the Indian taxpayer is to go to provide Europeans with the luxury of a separate hospital where the ubiquitous "native" may not trouble their vision. This might be a very good arrangement, but it does not embody the quintessence of justice. It looks like robbing Peter to pay Paul though we can not say it is, for that may mean for us a prolonged sojourn in the Andaman Isles."

ONE RESULT OF THE LAPORTE CASE.

SAYS the *New York Medical Record*:—"We learn from the *Press Medicale* that an Amiens fellow, relying doubtless on the Laporte case as a precedent, lately wrote a letter to a physician accusing him of having caused the death of his wife and child, ten years before, by performing craniotomy, demanding to have his loss made good by the payment of ten thousand francs within forty-eight hours, and threatening legal proceedings in case his demand was not complied with. We are glad to learn that the fellow was sentenced to fifteen days' imprisonment."

A MEDICAL STAFF CORPS FOR INDIA.

THE *Lawyer* says:—"It is, we believe, the first time that men of the Medical Staff Corps have proceeded for service to India. Surgeon-Major-General O'DWYER inspected a draft of the Medical Staff Corps on Monday last previously to the draft leaving for India, and expressed his satisfaction with their appearance and outfit. He also spoke of the responsibility of the position in which the men were to be placed, and urged them to uphold on all occasions the honor and credit of the corps."

SHORT NOTES.

At the meeting of the Council of the British Medical Association of February 19th, Dr. George Wyther, the acting Editor who has been associated with the editorial department of the journal for many years, and has recently been discharged the duties of acting Editor, was unanimously appointed Editor of the *British Medical Journal*. At the same time Mr. C. LEWIS GAYDON, who has been Sub-Editor for the last eleven years, was appointed Assistant Editor.

Mr. Banks-Gwyther, who shortly goes home on leave, will be deputed to visit the Birmingham Hospital with a view to advising the Bengal Government upon the system in use there for filtering and warming the air supplied to the wards. The proposal is to furnish the new Calcutta General Hospital, with a very similar apparatus differing, however, from that in use in Birmingham, in that it will cool the air, instead of warming it.

Amongst the Russian doctors who came to Bombay last year to investigate the plague was Dr. Redroff, who will be well remembered both in Bombay and in Poona. A telegram from St. Petersburg to the Times states that in consequence of some unpleasantness amongst the members of the Russian Commission before they returned, Dr. Redroff stabbed himself the other day through the heart with an Indian dagger which he had brought home with him.

The *British Medical Journal* says:—"It is wholly against the ethics and spirit of the profession to limit the spread of serial scientific literature that has been donated by physicians. In a recent review of an epitome of medical progress, one of our contemporaries argued against the need of such books. We emphatically dissent from such an opinion, believing it an instance of a bad business policy, of worse journalism, and of the worst professional spirit."

The following Resolution was proposed and passed unanimously by the Council of the British Medical Association:—"The Council desires to convey to Mrs. Ernest Hart its expression of deep sympathy with her in the loss she has sustained, and to place on record its recognition of the memorable services rendered by Mr. Ernest Hart to this Association during his tenure of the office of Editor of the *British Medical Journal* for more than thirty years."

Amongst the names mentioned in the despatches from Major-General Sir B. Blood, K. C. M., and Major-General E. B. Ellis, C. B., regarding the operations of the Mahaland and Mohmand Field Forces were those of Surgeon-Captain Hugo, Surgeon-Colonel J. O. G. Kitchin, Surgeon-Colonel E. Townsend, Surgeon-Captain W. E. Bennett, and Surgeon-Colonel J. F. Williamson.

The Madras Municipal Commissioners, at a recent general meeting, adopted the following resolution:—"The Commissioners desire to place on record their appreciation of the services rendered by Dr. J. H. H. H. H. as Health Officer of the Municipality during his tenure of office, and the consideration was in which he discharged his duties."

Criticism has been freely heaped upon the *British Medical Journal* by a physician of New York who has been in England to a night call from a grocer who had refused to pay the grocer's bill. Perhaps some time the *British Medical Journal* will find a good way to make sure of timely payment from its subscribers by paying for what it receives as it goes along.

In view of the insubstantial condition of Bangalore, it has been decided to completely evacuate this place as a military station during the current year, pending the installation of a pipe water-supply. This will enable the measures requisite for remedying the various sanitary defects of the cantonment to be successfully carried out.

Mr. William Haly, who has been for years on Messrs. Smith, Stanistreet & Co.'s staff in Calcutta, and has during that time made a name for himself in connection with Indian materia medica, is returning to England for a short period, and towards the end of the year will come back to Calcutta to start a business on his own account.

Professor Turner, of Paris, died recently in that city, at the age of seventy years. He was graduated in medicine in 1857, from the University of Paris, and held the chair of clinical obstetrics in that university at the time of his death. He was well known for his many works on obstetrics.

We understand that Surgeon-Major-General James Cleghorn, M.D., C.S.I., the Director-General, Indian Medical Service, goes on furlough almost immediately and Surgeon-Major-General Robert Harvey, M.D., D.S.O., I.M.S., will officiate in his high office.

The Prussian police authorities have issued an ordinance declaring that the so-called electro-homoeopathic remedies of Count Matisel as prepared by Apotheker Santer in Geneva, have nothing in common with the homoeopathy of Hahnemann, and are quite worthless.

Truth puts these words in the mouth of a physician regarding his prescriptions: "What I have written I have written, and neither I nor you nor anybody else can read it." And the *British Medical Journal* adds: "There is a good deal of Truth in it, and we are very sorry to say a little truth, too."

The plague party's brake, containing Sir James Campbell, Drs. BAINBRIDGE, JENNINGS, and DIMMOCK, and Messrs. James, Gell and Alexander, capsized at the corner of Batunga. Dr. JENNINGS, was picked up unconscious, two of his ribs being fractured. He is doing well.

The Secretary of State has approved of the temporary postponement of the abolition of the post of Secretary to the Surgeon-General, I. M. S. Surgeon-Captain Grayfoot continues in the appointment till the work connected with the plague ceases.

The Surgeon-General with the Madras Government has issued instructions to the Medical Officers at the General Hospital, the Ophthalmic Hospital, and the Maternity Hospital to test the value of aluminium vessels for use in hospitals, in place of copper and brass, as at present.

Surgeon-Captain F. P. Maynard, on deputation on plague duty, is appointed temporarily to act as Second Resident Surgeon, Presidency General Hospital, Calcutta, during the absence, on deputation, of Surgeon-Captain F. O'Kinealy, or until further orders.

For scientific merit a gold crown with a silver medal has been awarded to Dr. Benode Behary Banerjee, M.D., LL.D., the grandson-in-law of H. H. Maharaja Bahadur Sir J. M. Tagore, K.C.S.I., by the Scientific Society, London.

The use of cotton gloves in operations, originally introduced by Professor Mikulicz, is gradually spreading throughout Germany. They are said to be quite a step forward in the final acquisition of perfect asepsis.

A Medical Botanist's Manager at Kettering bandaged an old lady's wrist, and treated her for a sprain. It afterwards appeared that there was a fracture, and a jury has given a verdict against the botanical expert, awarding 40*l.* damages.

Brigade-Surgeon-Lieutenant-Colonel Akshadhar Chomble M.D., Surgeon Superintendent, Presidency General Hospital, Calcutta, retires from the service, with effect from 1st March.

An estimated whilst attending to an albuminuria Dr. J. C. Young, of the National Benefit Life Assurance Company, says that football and bicycling greatly impair a person as a risk. Premiums will probably be enhanced.

At Green River Wyoming, a series of wells have been discovered, yielding 60,000 gallons daily of concentrated soda solution from which 100,000 pounds of pure sal soda are daily crystallised.

Dr. Anthony Brownson, Chancellor of Melbourne University, died a short time ago. He was first a practising physician in London, but went to Victoria in 1853, and was the founder of the medical department of Melbourne University.

Small-pox is becoming prevalent at Poona, and a number of cases are under treatment at the Lamson Hospital, among them being Sister Esther, the Lady Superintendent in charge of the Nursing Staff, and Miss Barnes, one of the nurses.

Three civil pupil nurses have recently been admitted into the Eden Hospital, Calcutta, in consequence of the inability of the military authorities to find candidates for the three vacancies, which occurred among military pupil nurses.

The marriage of Miss Gross, eldest daughter of the Hon'ble Mr. J. Gross, of the Madras Governor's Council to Surgeon-Captain G. Giffard, I.M.S., took place at St. George Cathedral, Madras, last week.

We are glad to learn that Mr. P. S. Blakes, of the Medical College, Calcutta, has just passed the second examination of the Royal College of Surgeons and Physicians (London) in Anatomy and Physiology.

Brigade-Surgeon-Lieutenant-Colonel F. C. Barker, M.D., F.R., C.S.I., has been appointed to act temporarily as Superintendent Lunatic Asylum, Colaba, in addition to his own duty.

Dr. George Watt, M.B., C.I.M., Reporter on Economic Products to the Government of India, proceeds on furlough for eight months from May next.

A novel, entitled *The Stars in their Courses*, by Editha Ewens, who is said to be the wife of a member of the Indian Medical Service, has just been published.

Under instruction from Command Head-Quarters, Surgeon-Captain M. S. Peck, I. M. S., on reporting arrival at Calcutta from Bombay, will proceed to Dibrugarh, Assam, for duty.

A Hospital Assistant who accidentally cut himself whilst conducting a *post-mortem* examination on a plague corpse at Hardwar, has contracted the disease.

A correspondent writes:—"In re Dr. Neild-Cooke, it may be of use to know that he got the diploma of D.P.H., Cambridge, in 1896."

Steps are being taken to expedite the despatch to India of such surgeons on probation at Netley as may have successfully completed their course of instruction.

The services of Surgeon-Major Baker, Besikency Surgeon, Turkish Arabia, have been replaced at the disposal of the Bombay Government.

Ophthalmologists now recognise the bicycle eye, a specific disease brought on by the dust and dirt introduced into that organ by riding on the road.

Surgeon-Lieutenant-Colonel Cumins returns from the Central Provinces and resumes charge of the Inspector-Generalship of Jails in Bengal on the 7th instant.

Surgeon-Lieutenant-Colonel G. Frisoe, M.D., I.M.S., has been permitted to retire from the service.

In Bulgaria the proprietor becomes liable to fine and imprisonment if a medicine fails to fulfil its advertised claims.

Surgeon-Captain Williams, A. M. S., was married at Agra to Miss Halliday, and the wedding was largely attended.

STUDY OF THE EFFECTS OF CALUMET.

Calumet, a German Beer, was given to 35 students during the week ending 14th January 1902. The results are as follows:

Week ending.	Calumet.	Beer.	Wine.	Spiced wine.	Other.	Total.	Students who drank.	Students who did not drink.
14th January	3	...	128	86	248	459	100	20
21st January	4	...	117	102	268	486	...	27
28th January	9	8	98	57	227	394	...	30
5th February	13	8	104	76	241	437	...	39

Current Medical Literature.

MEDICINE.

Nerve Deafness in Diphtheria.

Attraction of the labyrinth or auditory nerve in diphtheria is of the greatest rarity; it is mentioned by almost all authorities. The following case is described by Dr. J. C. WILSON in the *American Journal of Medical Sciences* for October 1897. A woman, aged thirty-three years, complained of sore-throat. The tonsils were covered by a dense, greyish-white exudation with abruptly margined borders, surrounded with hyperemia. On the fourth day there were distressing tinnitus and loss of hearing, which latter became total on the next day. Antitoxin was injected, and the membranes disappeared in the course of two days. The tympanic membranes were bright red, but glistening and not bulging. Bacteriological examination failed to show the bacillus. On the ninth day there was loss of power of the muscles of the back of the neck, and later double vision and paralysis of accommodation ensued. The patient gradually recovered and the membrana tympani became normal, but the tinnitus continued. Deafness was absolute with all tests. Six months after the attack the deafness, tinnitus, and slight vertigo persisted, as well as paralysis of the muscles of the neck. Dr. WILSON suggests that the failure of the bacteriological diagnosis may have been due to the previous use of antiseptics. He fairly insists that the condition of the throat, the rapid disappearance of the membranes after the use of antitoxin, leaving superficial erosions, and the paralysis justify the diagnosis. The deafness was probably due to labyrinthine lesions. MOORE, on examining the bodies of three children who died from diphtheria, found the membranous semicircular canals filled in many places with coagulated lymph, whilst the middle ears showed merely catarrhal changes.—*Lancet*.

Alimentary Glycosuria.

KARL has studied alimentary glycosuria occurring after beer drinking. KRATZSCHER has also made some similar observations. KARL examined for this purpose some 100 students. He was able to vary the kind and amount of the beer taken, as well as the time of drinking and the diet. The urine of four young brewers who had drunk large quantities of beer in the fasting state or at breakfast time was also examined, and in one case sugar was found. The exact composition of the beer, especially in regard to sugar, was ascertained. The students examined mostly drank 1 to 2 litres of beer in the morning. Of 57 drinking a large beer, the sugar reaction was positive in 4 cases, or 7 per cent. In the case of an export beer, 5 out of 14, or 35 per cent.

had glycosuria. In 25 students drinking 1 to 1½ litres of Rosen beer, no glycosuria was observed. Out of 19 cases drinking large quantities of an Ehrlingdorf beer in the evening, 1, or 5 per cent, had glycosuria. Of 11 other students drinking largely of all sorts of beer, only 1 had glycosuria. It was often impossible to repeat the examination in these cases. The predisposition of the individual is always important in these cases, for those who drink the most are not always those who have the glycosuria. The more marked presence of the glycosuria in the morning was due to the more rapid absorption. Both BRAUNFELD and ENGELMANN showed that alcohol favored the appearance of an alimentary glycosuria. Perhaps the sugar in the urine in these cases was due to the action of the alcohol, but other substances in the beer may be responsible. The author thinks that at the present moment there is no satisfactory explanation of the alimentary glycosuria following upon beer drinking.—*Brit. Med. Jour.*

Habitual Constipation.

THE causes of habitual constipation are: Heredity; the habit of suppressing the desire; unsuitable diet—too abundant, deficient in water, too easily absorbed, or insufficient in variety; sedentary habits (although abstinent habits constipation may occur even in those who lead an active life); disturbances in the circulation (heart disease, mechanical pressure, pregnancy); displacement of the bowel; intestinal adhesions. The treatment is given as follows: (1) Dietetic, (2) physico-mechanical, (3) medicinal. In the first method, such foods should be given as are known to increase peristalsis. The "physico-mechanical" includes athletic exercise (often of great value), electricity and enemas. The disadvantage of enemas is that ultimately small quantities of fluid do not suffice, and large quantities are needed, the intestine and become useless. Regular attempts at distention with slight pressure are recommended. Medicinal treatment is discussed under two groups, mild and more powerful purgatives. An efficient rhubarb preparation is very useful. Calomel is very useful in children. Castor oil is unsuitable for constant use. Large injections of olive oil are of value.—*Sanitary Med. Jour.*

Chief Nervous Affections of Alcoholism.

ALCOHOLIC coma, delirium tremens with visual hallucinations, restlessness, fear, tremor, and failure of sleep and appetite, acute traumatic delirium occurring after wounds, mania, a psychosis without tremor but with racing and violent muscular exertion with loss of consciousness and delirium over the motor and sensory trunks, chronic poisoning, chronic

HYGIEINE

Instrument for Dilating Superficially the Urethra.

Dr. HENRIE has devised an interesting adaptation of the catheter for the treatment of the hyperplasia of the chamber of the urethra. For each kidney, HENRIE has devised an instrument by which the bladder, especially in women, is divided into equal portions, and the urine discharged into each finds its way out of the ureter through separate channels. The appliance consists in a tube of thin metal 4 cm. long, 1 cm. thick, carrying within its lumen a solid septum extending 4 cm. beyond the proximal extremity and thus forming a partition within the bladder and the ureter 8 cm. long. The divisions formed in the bladder terminate at the distal extremity of the tube in two smaller tubes, to which test tubes can be attached and the secretion from each kidney collected separately. The free proximal extremity of the septum terminates in a blunt point, from which pass off to either side two fine curved wires. The tube and its prolongation are curved after the fashion of Hegar's cervix-dilator, so that the instrument adapts itself readily to the posterior aspect of the symphysis pubis. In the employment of the device the patient sits at the edge of the bed, with the feet supported and the thighs spread far apart. The conical proximal extremity of the instrument is introduced into the ureter with its convex aspect forward. The urine present in the bladder escapes. The viscous is then irrigated with warm boric acid solution and all fluid is removed with the aid of a finger introduced into the vagina. The urine, as it is discharged from either ureter, now collects in the bladder on either side of the artificial septum and is eventually discharged through the small tubes.—*Jour. Amer. Med. Assoc.*

Influence of Optic Neuritis on the Treatment of Cerebral Tumours.

J. B. RISIEN RUSSELL calls attention to the necessity for caution in certain cases of intracranial tumours in which the presence of optic neuritis may lead to errors of diagnosis and treatment. Too much dependence should not be placed on the existence of neuritis alone in the diagnosis of brain tumour. RUSSELL regards the various causes of optic neuritis, such as are found in albuminuria, lead poisoning, hypermetropia, anaemia, etc., as well as intra-cranial tumours of diverse origin, and concludes that while the presence of optic neuritis has a marked influence on the methods which we employ in the treatment of cerebral tumours, there is a risk that too much reliance on this sign as an indication of the existence of such tumours, in the absence of other conclusive evidence of their presence, may lead to errors of diagnosis and faulty attempts at treatment.—*Treatment.*

Treatment of Soft Chancres by Prolonged Irrigation.

Two Italian physicians, MALURANGI and BONADUCCI have been treating venereal ulcers with prolonged irrigations of hot water at a temperature of from 47° to 53°C (106°-117°F.). The irrigations are commenced at the former temperature which is then rapidly raised by heating the irrigator with an alcohol lamp, or more simply, by the addition of some boiling water to that in the irrigator. The irrigation should be interrupted from time to time to give the patient a chance to cough and the whole course, lasting a half-hour, should be repeated daily. Under the influence of this heat, the ulcer becomes very red in a few minutes and there is a sensation of heat in the body, accompanied more or less by profuse perspiration. The ulcer is finally covered with soft granules,

and light sloughs of the chancrous material. This method causes the irrigation on the tissues of the ulcer to rapidly disappear, and transforms it into a healthy wound which heals readily. In the only case in which the writers employed this plan of treatment from two to three irrigations were all that were necessary.—*La Sanita.*

A Venereal Disease.

MARVIN dwells on the remarkable disease observed in China amongst the poor, who die in kind of gangrene of antritis (carbuncle). The skin on exposed parts becomes excoriated and itches severely. The symptoms have been attributed to an acarus which is found on the skin of antritis. But the parasite has not been actually found in any patient. MARVIN, however, believes that the theory about the Chinese disease is correct, for in Mauritius there is an acarus known as *holothyrus scuticella* (Gervais), which abounds in most, in the cold and damp highlands of the island. Poultry cannot be reared in these districts as the acarus causes fatal pharyngitis. Native children suffer in the same manner. Some specimens of *holothyrus* were sent to MARVIN. They were all dead. He fixed them by plunging to his forearm. In a few hours they set up severe irritation, eczema, and prurigo. The live *holothyrus* must be a powerful irritant to mucous membranes. It measures under one-fifth of an inch in length.—*Brit. Med. Jour.*

Treatment of Carbuncles with Faguet's Caustery.

MOTY reports a case of anthrax affecting the lower lip, with secondary foci on the breast, the forearm, and the shoulder, treated by puncture with Faguet's caustery at each suppurating orifice and subsequently drawing with carbolic acid. In some of the smaller foci the disease was checked at once by the puncture, and no more pus was formed. As for the deep-seated ones, the author remarks that the patient's sensations are the best guide to their situation, for at first they do not betray themselves by physical signs, yet it is of importance to treat them promptly whether pus has formed or not. The part may be cocaineized before the caustery is applied.—*N. Y. Med. Jour.*

Paralysis of the Intestines after Abdominal Operation.

ERGSTROM says that paralysis of the intestines which follows laparotomy, sometimes preceding death, does not always result from sepsis. He cites four cases in which death followed operation after fifty-seven hours, seven, eight, and ten days respectively. In these four cases there was not the least trace of peritonitis, which there would certainly have been if death had been due to sepsis after such an interval of time. Moreover, in one case the contents of the abdominal cavity were examined bacteriologically one hour after death and were found to be absolutely sterile. According to the author, a careful stimulation and nutrition of the patient, if necessary, per rectum, is a most important factor in preserving life.—*Med. News.*

New Incision for Appendicectomy.

VIGIAR reaches the appendix by an incision one inch above and parallel to the iliac spine, from the edge of the external oblique to a point just above the anterior superior spine of the ilium. The muscles, which are better developed here, are separated in the direction of their fibres, and the belly opened. The advantages claimed are the impossibility of hernia, because of the wound's position; the most dependent point for drainage; and the facility with which the appendix is found. The greatest drawback is the extreme depth of the wound.—*Brit. Med. Jour.*

OPERATIONS AND OPERATORS.**Deep Incision of Cervix in Labour.**

WAGMAN published last year an important paper, in the Russian language, on the results of this operation, after SEITZ and SCHNABER, in the Prague Maternity School. In 2,653 labors (1892-95) incision was practised 34 times, namely, one incision in 1 case, two incisions in 8 cases, three in 9, and four in 6. In 11 cases the incisions were sutured after labour, 7 uniting down to the edge of the external os by first intention. The indications for incisions were: prolapse of cord 8 cases, eclampsia 3, dangers threatening fetus 17, cancer of the portio 1. Delivery was completed by symphysiotomy and forceps in 8 cases, by the forceps alone 14, by turning and extraction 5, and by perforation and cranioclasty in 2. The presentation was: vertex 31, face 1, brow 1, and transverse 1. The pelvis was capacious in 9 cases, and contracted more or less in 15. In 8 cases the incisions were enlarged by laceration, in 8 they bled severely, the hemorrhage required the tampon in 1 of these cases, and was checked by suture in the others. In several cases median incisions were made into the vagina and perineum. Of the children, 14 were born alive, and 8 in suspended animation (6 saved), whilst the remaining 2 were the cranioclasty cases. The puerperium was normal in 17 of the patients; in 3 there was a slight rise of temperature, in 2 parametritis, in 1 mastitis, and in 1 endometritis, salpingitis, peritonitis, and fatal sepsis. This patient was mentally afflicted and very uncleanly; there was strong evidence that the artificial incisions were not the channels of infection.—*Brit. Med. Jour.*

Early Symptoms of Puerperal Infection.

SLIGHT elevations of the temperature (37 to 38.2 degrees, axilla), usually once a day, sometimes more frequently, separated by intervals of lower temperature; the pulse more rapid even when the temperature is not elevated, 80 and above. The sleep at night is also an important indication, as good sleep denotes a more favorable prognosis, while insomnia in connection with higher temperature and more rapid pulse, with a sensation of chilliness in the back, trunk or limbs, and a change in the lochia, as decrease, suppression, fetidity, indicate approaching infection.—*Jour. Amer. Med. Assoc.*

Forceps Delivery.

DR. DAVIS, in a recent lecture on *delivery by forceps*, stated that the instrument which, at the present time, is giving the most general satisfaction, not only in his hands and the obstetric clinics in this country, but also abroad, is that known as the Simpson forceps. It is necessary that the instrument should be well made and long enough for high application. The efficiency of the forceps is greatly increased by the use of axis traction tapes. These may be passed through the februa, or, what is better, the blades may be perforated by two holes, through which the tapes should be passed. An axis traction bar, while convenient, is not essential.—*Phil. Poly.*

Effects of Hereditary Syphilis upon the Placenta, Cord, Fetus and Child.

J. D. BISSSELL, writes.—The cause of death of syphilitic children in utero, is in the vast majority of cases due to a diseased condition of the placenta or cord rather than to the breeding of the syphilitic virus in the fluids of the fetus itself. Six cases are reported, three of which were born dead and macerated, and in each there were positive evidences of fatal interference of the blood supply to the fetus. In the cases born alive, no evidence of disease was appreciable in the placenta or cord. In one of the cases the vessels of the cord were occluded for about three inches by a deposit, the result of inherited syphilis. Another case presented a placenta

which had undergone chorio-amnionitis; it was small, yellowish in color, very friable, the lobes being infarcted in the villi, transforming the placenta into a membranous organ. At the junction of the cord with the abdomen there was a failure of development in the umbilical vessels, the vessels being pulsations, but not sufficiently so to allow the requisite amount of blood to pass to and fro, which undoubtedly was an active factor in the early death of the fetus. Hydramnion, a condition somewhat characteristic of a syphilitic pregnancy, occurred in another case, evidently the result of interference in the fetal circulation occasioned by the diseased placenta. Another died at five and one-half months due principally to failure of development of the umbilical vessels.—*Phil. Poly.*

Sudden Death in the Puerperium.

1. PULMONARY embolism is the cause of death in most of these cases. 2 It is rare, but so shocks a community when it occurs that it is advisable to take every precaution to guard against it. 3. Phlebitis, varicose veins, prolonged labor, hemorrhage, anemia, sepsis, cancer, syphilis, etc. predispose to its production. 4. In the presence of peripheral thrombosis, etc., absolute rest must be enjoined, especially between the second and third weeks of the puerperium, as this is the disintegrating period of the clots. The danger should also be explicitly pointed out to both patient and attendants, thus insuring to some extent a healthy co-operation. 5. The extreme changes in the blood usually ascribed to pregnancy and the puerperium are erroneous, and not corroborated by modern investigation. 6. Sudden death from air embolism in the puerperium is doubtful from physiological, pathological, and rational stand-points. 7. Shock is both a direct and indirect cause of death in the puerperium, and should be guarded against. 8. Organic heart affections, kidney trouble, etc., are capable of producing death at any time, and should not be overlooked in the puerperium.—*GALTMAN, N. Y. Med. Rec.*

Ligation of the Bases of the Broad Ligaments for Interstitial Uterine Fibroids.

MARTIN summarizes as follows:—"It is a minor operation; reduces the tumor by starvation, and cures the hemorrhage by depriving the uterus of two-thirds of its blood-supply; does not unsex; is applicable when radical measures cannot be undertaken, because of the condition or fear of the patient, or because of mechanical obstacles; and it is specially indicated in small bleeding fibroids occurring at the menopause. It is not applicable to pedunculated, subserous, or submucous fibroids. In fourteen cases, in which two or more years has elapsed, there has been one return of hemorrhage and one of pain."—*Phil. Poly.*

Hypodermic Injections of Cocaine in the Vomiting of Pregnancy.

In five cases of the vomiting of pregnancy where morphia injections and cocaine given by the mouth had failed, Professor TIBONI, of the Turin Obstetric Clinic, was able to effect an immediate cure by means of hypodermic injections of hydrochlorate of cocaine. One-seventh of a grain was thus administered just before food was taken, the puncture being made in the epigastrium and the injection repeated two or three times a day. It was found that this enabled the patients to retain their meals, and under this treatment they increased in weight and their condition improved in a marked degree, no unpleasant effect on the pulse, the respiration, or the temperature being observed in any of the cases. As soon as possible, of course, the cocaine was stopped and the vomiting did not show any tendency to return. Dr. FOSSI, who writes on these cases, suggests that it is probable that similar treatment may be found valuable in vomiting due to other causes.—*Lancet.*

Relationship between Blood Changes and Leucocytosis with Blood Dissolution.

As a result of observations in cases of malarial intermittent fever, supplemented by experimental studies in which blood dissolution in animals was effected in various ways, EDWARDS found that such dissolution is attended by a considerable degree of leucocytosis, together with metabolic changes, as manifested by increased elimination of uric acid and xanthin bases, primary increase with secondary diminution in the elimination of phosphoric acid; and increased elimination of chlorides. The chlorides and the phosphoric acid appear to stand in vicarious relations with one another, the retention of the one corresponding with increased elimination of the other. The increased elimination of alloxur bodies is dependent principally upon destruction of the leucocytes. Probably other nucleated cellular elements take part in this process, and in slight degree also the nuclein containing albuminous constituents of disintegrated red blood cells. The mother substance for the formation of alloxur bodies is in large part contained in the plasma and the serum and in smaller degree in the red blood corpuscles. The amount of uric acid-forming substance depends upon the number of leucocytes in the blood. Normal blood serum induces only a slight increase in the elimination of alloxur bodies and leucocytosis; typhoid serum none at all; and leukemic serum a very considerable increase. The primary increase induced by leukemic serum results from the presence of uric-acid-forming substances; the secondary increase is the result of the increased production and destruction of leucocytes dependent upon the activity of the leukemic serum. The leucocytosis attending blood dissolution is an effect of the co-operation of three causes: (a) the direct leucocytotic action of the blood poison; (b) the chemical substances (especially nucleins) set free as a result of the destruction of the cellular elements of the blood; (c) the remains of disintegrated blood corpuscles circulating in the blood. The leucocytosis induced by injection of corpuscular elements into the blood is a pure phagocytosis and leads to no notable destruction of leucocytes. The increased destruction of leucocytes in the blood in cases of infectious diseases is due to the presence of a leucocytolytic substance.—*N. Y. Med. Rec.*

Diagnostic Importance of Chloride in the Urine.

In chronic affections it seems to be definitely established that progressive or abrupt diminution of the chlorides in the urine indicates a serious phase of the disease, when it is not due to special alimentation. FINK contributes to the *Arch. Clin. de Bordeaux*, September, a study of the chlorides in the urine of pregnant women, coinciding with the statement that the passage of chlorides into the urine is in direct proportion to the permeability of the renal filter for toxic products, and hence, in normal pregnancy or with slight albuminuria, the amount of chlorides is always large, averaging 15 grams and never less than 13 grams in twenty-four hours. But if the albuminuria is complicated with vomiting, vertigo, etc., the amount of chlorides is materially diminished and evidently in parallel proportion to the degree of intoxication. AUROCHSCHILD having observed that the vomiting of pregnancy resembled the symptoms of animals deprived of salt, administered saline in large quantities and obtained a prompt, complete and permanent cure. He reported at Moscow that his usual combination is POTASSIUM'S saline mixture, phosphate of lime, Glauber salts and bromides.—*Jour. Amer. Med. Assoc.*

According to the views of the author, the hepatic changes leading to cirrhosis, is never the result of an interstitial inflammation, but that it depends upon a more inflammatory process affecting the glandular cells of the peripheral parts of the acini. Human cirrhosis, he thinks, corresponds exactly with experimental cirrhosis as produced by phosphorus. Rabbits were injected with 1 or 2 mg. of phosphorus dissolved in olive oil. According to their individual powers of resistance to the poison the rabbits lived different lengths of time. Thus of 8 rabbits experimented on, 4 died after two injections of 2 mg., whereas 1 lived to receive sixty-nine injections of 1 mg. The liver of the last-mentioned rabbit was found to have a finely granular surface, analogous to that seen in human cirrhosis of the liver. In the experiments anæmia twice occurred, but jaundice never. In some cases albumen and hyaline casts were found in the urine. WAGNER thought that large doses of phosphorus affected the hepatic parenchyma, whereas small doses, affected the interstitial tissues; but AUROCHSCHILD thinks he has proved that the hepatic cells are the only part ever affected. The difference he finds is that with large doses all the cells of the acini are damaged, whilst with frequently-repeated smaller doses the peripheral portions only of the acini are affected; in the former case the hepatic cells may be destroyed and their nuclei may disappear, but in the latter case no cells are destroyed, though the protoplasm of the affected cells is diminished, so as to give rise to the erroneous supposition of interstitial inflammation with newly-formed tissue between the acini.—*Brit. Med. Jour.*

Toxins and Antitoxins.

MUCH speculation has been expended upon the origin and nature of these substances. Do they exist in the serum or cells of the blood? Have the cells anything to do with their production? After they are formed are they purely inert substances acting in a chemical manner? Many such questions have engaged the attention of workers in the past and will continue to do so in the future. Recently CALMETTE and DELANDE have contributed a most interesting paper in which they suggest that immunity, whether natural or acquired, may be a physical and not a chemical phenomenon. They investigated the antitoxic properties of blood serum from various animals, taking the reaction to doses of abrin, as the most frequent criterion. The following are some of their results:—(1) The serum of animals, naturally refractory to certain toxins, has no action thereon *in vitro*. (2) Cold-blooded refractory animals can acquire immunity against fatal doses of toxin, without their serum becoming antitoxic. (3) Antitoxin, or at least the active substance of certain antitoxic serums does not alter toxins when mixed with them *in vitro*. (4) Leucocytes may retain their antitoxic powers after being thrice washed free from serum. (5) Certain inactive substances, such as bouillon, or normal ox serum (having no action on toxins), may, when injected into fresh animals, confer more or less perfect immunity upon them. They therefore think that immunity cannot be due to the presence of a chemical substance in the serum, having the power of altering the toxins; and, further, that it more probably results from a special property of the cells. They cleverly suggest that these may yield passively to the influence of toxins, as a bar of soft iron does to a magnet. The functional state of the cells may be modified by the conditions of the surrounding medium, or their own composition, as under the influence and tolerance of certain poisons; just as the bar of soft iron may be converted into steel, and yet retain its magnetization and its power of transmitting it.—*Brit. Med. Jour.*

PREVENTING DANGEROUS DISEASES AND CONSPIRACIES.

Funeral Dangers.

There is saying that "there is never a little but another is soon" might be adapted to funerals. You think the conventional mode of showing respect to the dead holds in its turn its risks. By a sad coincidence, a correspondent had addressed to me a letter on this subject, when the tragic death of Mr. CHARLES HARRISON occurred to point the moral he wished to draw. There can be little doubt that the sudden attack of subacute laryngitis which terminated Mr. HARRISON's mortal life was due to exposure during his attendance at the funeral of Sir FRANK LOCKWOOD. It is suggested that the use of a skull cap, such as the late Dean STANTON used habitually to wear even on ordinary occasions at the Westminster Abbey services, would prevent danger, and this might do something to diminish the risk. But the fact is that the depression produced by all the circumstances of a funeral, and the sudden change from a hot carriage or a crowded church to the damp grass and chilling air of a cemetery are very apt to produce a chill which settles on a man's weak point. In the case of Mr. HARRISON, who had long suffered from a chronic laryngeal affection, it was the larynx, but in another it may be the lungs, in another the kidneys. In Scotland, we believe, and certainly in many Latin countries, it is not the custom for ladies to attend funeral ceremonies; and the modern custom of holding a special service which may be attended by friends, while only a few near relatives go to the cemetery, has much to commend it, and probably in time will afford at least a partial remedy.—*Brit. Med. Jour.*

Disseminated Knowledge of Hygiene.

BUNSENBERG, of Vienna, urges the establishment of special chairs of hygiene in the medical colleges to train young physician-hygienists for the purpose of instructing the public in the principles of hygiene. The State should appropriate funds to support this propaganda, and send qualified persons into the rural districts to lecture and demonstrate the subject with special efforts during fairs and similar gatherings. Pamphlets describing the proper measures to be taken should be given to parents when births are reported, children inculcated in the schools and on other occasions of the kind. The influence of the clergy should be utilised and the theological seminaries should have facilities for the instruction of the students in the principles of hygiene, which should also be taught the children in the schools.—*Journ. Amer. Med. Assoc.*

Dangerous Fruit Preservers.

THE *Sanitarian* warns women against the various antiseptics sold to preserve fruit. Salicylic acid is the main substance of which they are composed. Salicylic acid is a powerful antiseptic; it hinders or prevents fermentation, the souring and putrefaction of milk. It completely arrests the conversion of starch into grape sugar. This action is directly opposed to the process of digestion, and for this, if no other reason, its use should be unreservedly condemned. The use of the acid has been condemned by most of the European countries having pure food laws. In France it is forbidden. In Austria, Italy, and Spain it cannot be used without the danger of incurring a heavy penalty, and all South American States having poor food laws have absolutely forbidden its sale. The laws of many of the States forbid its use. Its use in food is prohibited in Pennsylvania.

Preservatives, under various high-sounding names, intended for use in private families, and said to be perfectly harmless are on the market. Salicylic acid is their main ingredient. The conscientious and careful housekeeper should put an

absolute veto upon the use of the anti-fermentation agents so rarely any need for them; and that pure fruit and vegetables are safe and the proper direction for obtaining by heat, etc., are carried out, causing the general goods of all descriptions can be prepared that will remain in good condition for years without the aid of any preservative whatever. Any good housewife who has no feeling of hygiene takes a woman's pride in putting up her fruit is a hygienic way and tends to no short cut to have a little trouble and cost. She knows that in the end it costs more and endangers, to some extent, the health of her family and herself. It is only the slipshod, don't care, careless or ignorant woman who uses the cheap drugs to preserve her fruit.—*Med. and Surg. Rep. Worry.*

MODERN science has brought to light nothing more curiously interesting than the fact that worry will kill, and the way in which it kills is stated to be that worry injures beyond repair certain cells of the brain. The brain being the sensitive centre of the body, the other organs become gradually injured, and when some disease of these organs or a combination of them arises, death finally ensues. Occasional worrying of the system the brain can cope with, but the iteration and reiteration of one idea of a disquieting sort the cells of the brain are not proof against.—*N. Y. Med. Rec.*

Antisepsis of the Barber Shop.

PARIS barbers and hair-dressers are now obliged in accordance with police regulations to employ sanitary measures in carrying on their business. They are required to use only nickel-plated combs, to substitute pulverisers for powder puffs, to cover the hair cut off with sawdust, and have it promptly removed, and to place all metal instruments, razors, shears, combs, clippers, etc., in a steriliser for ten minutes before they are used.—*Med. News.*

Notification of Puerperal Fever.

In a report lately issued by Dr. EDWARD YOUNG, of Crawe, dealing with questions arising under the Infectious Disease Notification Act, he says of puerperal fever:—"In my experience, the notification of this disease proves too great a strain upon the loyalty of many medical practitioners, this being the case specially with regard to better class patients. The diagnosis of the disease should not prove a difficulty, for the term puerperal fever in modern medicine signifies puerperal septicæmia, a form of the septic disease familiar to all surgeons. It is not a specific fever such as typhoid, for example, but a form of blood poisoning, brought on specially during the lying-in period by such things as bad hygienic surroundings, the use of dirty instruments, sponges, etc., and contact with infectious diseases such as erysipelas and scarlet fever. Being extremely infectious, and being also likely to be carried about by gowns and bedwires, it is highly important that it should be notified, and notified most loyally, to those having the control of the public health administration."—*Treatment.*

Morphine Habit as a Legal Defence.

A kleptomaniac in one of the British courts plead guilty, and her counsel assured the bench that she was in no want of money, but had sufficient means to enable her to live comfortably, and asked that she be released "temporarily on the ground that the theft was due to the effects of the extensive use of morphine." According to the testimony, she had consumed ninety-six grains of morphine in a single week. The magistrate suspended judgment, upon the defendant giving security in £50 to appear for sentence when required. Dr. QUINSON'S daily consumption of laudanum was nine ounces, and there is a case on record where 120 grains of opium were taken at once without producing death. The tolerance of opium and its salts proven in reality much more than old women's fables, and instances of enormous doses are in the possession of nearly every family practitioner. A poisonous draught of laudanum cannot be mistaken by even on record.—*Jour. Amer. Med. Assoc.*

HYDROCYANIC ACID AND PHARMACOLOGY.

Hydrocyanic Acid as Antidote to Chloroform.

MR. PATER, F.R.S.E., of London, observing that the respiratory action was nearly paralyzed and when death occurred during chloroform anesthesia, thought that hydrocyanic acid might prove of service as an antidote where the breathing was becoming shallow and weak, on account of the rapid and powerful temporary exciting effect this drug exerts on the respiratory centre. He administered hydrocyanic acid successfully in thirty-one cases of chloroform poisoning in animals mostly dogs, though some were cats, and the list includes also one calf, one sheep and one horse, the cases were those in which during anesthesia the breathing either stopped suddenly or became gradually slower. The hydrocyanic acid was administered in some cases hypodermically, in others was placed on the tongue. The good result was generally manifest in a very short time—half a minute to two or three minutes—the respirations being resumed and becoming strong and regular. In some of the cases, owing to the dose of hydrocyanic acid being rather large, the breathing became labored, when the administration of chloroform was resumed, so that a balance could be kept up between the toxic effects of the two drugs. These observations led fairly to the conclusion that hydrocyanic acid is of value as an antidote to chloroform, its beneficial effects being due to its property (when given in certain doses) of rapidly and violently stimulating and exciting temporarily the respiratory and cardiac centres, and so counteracting the depressant and paralyzing effects. The drug should be placed on the back of the tongue or injected hypodermically. In all his cases Scheele's acid was used, and he prefers it to the B. P. acid on account of its greater strength and consequent rapidity of action. For animals he considers one minim of Scheele's acid for every seven or eight pounds of body weight to be a fair average amount. It is well not to be too anxious to administer a second dose till perfectly sure the first has been futile.—*Med. & Sur. Rep.*

Compound Tincture of Benzoin in Enteric Fever.

JAMES C. PORTER, M.B., O.M., writes in the *British Medical Journal* :—

"I lately have had under my care several cases of enteric fever with excessive diarrhoea. I have in these cases tried a mixture of compound tincture of benzoin and water with marked success. I start by giving a dose of $\text{m} \cdot \text{v}$ of the tincture every two hours, and if the diarrhoea does not decrease in twelve hours I then double the dose. In all the cases after twenty-four hours' administration I have found marked benefit, the diarrhoea ceases, the stools are not so offensive, and the temperature is decidedly lowered, and the patient feels very much more comfortable. I attribute the success in these cases to

- "1. The internal antiseptic property of the drug.
- "2. The mixture forming a protecting coat to the inflamed bowel.
- "3. The antipyretic action of the drug."

Depilatory.

The following is considered the best and safest formula :—

Sulphide of barium in fine powder	...	3 oz.
Starch powder	...	5 oz.

Mix with a glass of water at the time of using, spread over the part required, and remove on the end of five or ten minutes.

A. Simple for Croup.

R. Saturated solution of	1 drachm.
Powdered sugar	...	10 grains.
Saturated tartaric acid	...	30 grains.
Hydrochlorate of nuxvomica	...	1 grain.
Hydrocyanate of cocaine	...	1 grain.
Powdered benzoin	...	15 grains.

A pinch of this to be sucked up the middle.—*Therapeutic Gazette.*

Linctum for Hyperidrosis and Abrasions.

R. Glycerinated soft soap	...	53 parts.
Water	...	27 "
Yasoline	...	15 "
Rose oxide	...	6 "
Essence of lavender	...	a sufficiency

M. *Præpar. Medical.*

Palatable Chloral Oil.

In the case of children who object to taking water off the dose may be made much less disagreeable if the oil is combined with glycerine and tincture of cardamom, as follows:—

R. Oil of roseal	...	3 ss
Glycerinal	...	3 iii
Ts. cardamomi comp.	...	3 i.

M. Sig. One dose.—*Med. News.*

Ointment for Hemorrhoids.

R. Sweet almond oil	...	2 drachms.
Oxide of zinc	...	1 drachm.
Bismuth subnitrate	...	1 drachm.
Benzoinated lard	...	6 drachms.

—*Chemist and Druggist.*

Chloral Pleasantly Combined.

R. Chloral hydrat	...	5 i. 3 i.
Tinct. cardamomi	...	3 ss
Syrupi	...	3 i.
Aqua cinnamomi. q. s. ad.	...	3 i.

M. A teaspoonful contains 10 grs of chloral.—*Med. News.*

Sea-Sickness.

R. Chloroform
Tincture of nux vomica	...	ss gr. x
Compound tincture of lavender	...	5 i.
Water	...	3 x.

M. A teaspoonful to be taken every hour until the vomiting and nausea have subsided, care being taken to shake the bottle each time before the dose is poured out.—*BARBAR.*

Ovarian Headache.

R. Ammon. bromid	...	3v
Ext. hydrastis d	...	3m.
Tr. gentian. co	...	3ss.
Aqua	...	3iv.

M. Sig. Dose: Teaspoonful three times a day.—*Dr. SINGER, Med. News.*

For Acute Rheumatism.

The following combination has been highly recommended :

R. Ammonii salicylicæ	...	3iii
Liq. papavini	...	3iv.

M. Sig. Teaspoonful in water every two or three hours.

Correspondence.

REFORMS IN THE MILITARY ASSISTANT SURGEONS' SERVICE.

To the Editor, "INDIAN MEDICAL RECORD."

SIR,—Having read the numerous letters in the *Record* and the petition the Indian Medical Association were so kind as to submit to the Director-General, I.M.S., on behalf of the Military Assistant Surgeons, for which we are very grateful, I take the liberty of sending you my views on the re-organisation of the I. S. M. D. (in whose ranks I have served for the past thirty-seven years) in the hope that you will give them room in your valuable paper. I propose to treat the subject under the following heads: (1) Recruiting, (2) Training, (3) Status, (4) Pay, Furlough Pay, and Pension, (5) Allowances, (6) Quarters, (7) War Reserve.

Recruiting.—The orders regarding the class of recruits are clearly laid down (i.e., Europeans and Eurasians), it goes without saying that several who have joined us are pure and simple native converts.

This condition of affairs should no longer be permitted to continue, as the element exists to an alarming extent already in the three services. There is no dearth of recruits. Let the Government pay a fair price, and the best article will be forth-coming, and we members, who at present are indifferent, would materially help the Government, were we to see the Government willing to meet us half way in our appeals.

I beg to submit that, all lads desirous of appearing for the examination for entrance into college, should present themselves at Military Hospitals only, there to be examined by an officer of the A. M. S. as to physical fitness, this officer also reporting on the desirability of the recruit. My reason for insisting that all candidates be reported on by an officer of the A. M. S., is that the A. M. S. officer is in daily contact with Military Assistant Surgeons, and it is only fair that he should have a voice in the matter, and be allowed to pick his own material.

Training.—Military Pupils should be termed "Military Medical Cadets," and should, in addition to the present medical education, be brought under thorough military discipline and training, the same as recruits in the Army (drill, including stretcher drill, gymnastics and, if possible, riding drill). An Adjutant to the Principal of the college to be appointed from among the Surgeon-Captains of the A. M. S., with a personal allowance of Rs. 100 per mensem and presidency house rent, with a tenure of office for 5 years.*

A first class Assistant Surgeon (under 5 years) as Superintendent, with an allowance of Rs. 45 per mensem and free quarters. Tenure of office 5 years. A Sergeant-Major, as drill and gymnasium instructor and disciplinarian.

A sufficient number of selected 4th year cadets to be made Sergeants, wearing badges of rank and receiving a small extra allowance. All cadets, on joining college, to be supplied with uniform, and compelled to wear the same within college precincts. Prior to leaving college and joining appointments, a kit allowance

of Rs. 150 be granted to each cadet, the sum to be granted to successful military students from *Records*, side Vol. II., part II., para. 1830 W.

Status.—The first requirement is a change of designation for the department. I would suggest, with all due deference, that it be known as the "Army Hospital Staff,"* consisting of Commissioned, Warrant and Non-Commissioned Officers as follows:—

- (1) Surgeon-Majors.
- (2) Surgeon-Captains.
- (3) Surgeon-Lieutenants.
- (4) 1st class Assistant Surgeons.
- (5) 2nd class Assistant Surgeons.
- (6) 2nd class Assistant Surgeons (under 5 years).

As the three senior grades are substantive Commissioned Officers with honorary rank, given in recognition of long and good service; the rank should be made substantive and the cumbersome designation of Senior Assistant Surgeon dropped.

Junior Warrant Officers should serve seven years in the lowest grade, promotion depending on their successfully passing an examination, for which they may be permitted to appear on completing five years' service.

I hold that, at present, lads joining from college do not appreciate their position, in fact have no idea of it, and as a consequence cannot maintain it. They should not be permitted to marry until after five years' service, and then only on sanction being obtained from P. M. O's. of districts.

Promotion to be obtained in the higher Warrant grades after five years service in each grade.

Promotion from the Warrant to the Commissioned grades by seniority and selection.

(a) Proportion to strength of Department

Juniors (both grades of 2nd class)
Senior Warrant Officers
Commissioned Officers

(b) Proportion in Warrant grades, one third in each of the three grades.

(c) Proportion in Commissioned grades, half as Surgeon-Lieutenants and half as Surgeon-Captains, out of whom specially selected officers receive commissions as Surgeon-Majors.

Distribution.—All 2nd class Assistant Surgeons under eight years' service to be Junior Warrant officers, and to rank as Sub-Conductors. 1st class Assistant Surgeons (under 5 years) to rank as Conductors, and those over five years' service as 1st class Warrant Officers.

Pay, Furlough Pay, and Pension.

Rank.	Pay per mensem Rs.	Furlough Pay £.	Pension & years Rs. per mensem.
2nd class Assistant Surgeons (under 5 years).	100	50	60
2nd class Assistant Surgeons (over 5 years).	150	100	100
1st class Assistant Surgeons	...	250	150
Surgeon-Lieutenants	...	350	200
Surgeon-Captains	...	450	250
Surgeon-Majors	...	500	300

* We fail to see where the need of a medical adjutant comes in.—ED., I. M. S.

* If a descriptive name is required, does anybody forbid I. M. S. or A. M. S. perhaps the term Anglo-Indian Medical Staff will be allowed.—ED., I. M. S.

Scale of pay while on leave in India to be as now obtains.

The present cost of the Military Assistant branch of the I. S. M. D. in the whole of India, on account of pay only, amounts to about Rs. 8,80,000 per annum (exclusive of the amount allowed for house-rent). The new scale, as in table above, would amount to Rs. 10,81,000, this after deducting Rs. 3,900 on account of rent paid by members of the service showing an excess of Rs. 1,73,000 (per annum). This amount, for the whole of India is trifling, and it would remove an acknowledged grievance. It is generally admitted that this department is the worst-paid of all the military services. The maximum pay asked for, is what is drawn by Officers of the Ordnance and Commissariat Departments of the Army.

ALLOWANCES.

(a). Medical charge allowance as at present :—

(b). Sub-Medical Charge Allowance.	No. OF BEDS.		Amount.		Remarks.
	From	To			
Station Family Hospitals	Rs. As. P.		When outside the Station Hospital compound.
General, Field, Section of Field, Station, Section or Non-district Hospitals ...	1	99	30	0	0
Do. do. ...	100	149	45	0	0
Do. do. ...	150	299	60	0	0
Do. do. ...	300	499	80	0	0
Do. do. ...	500	700	100	0	0

(c). Travelling Allowance.—By road, rail or steamer, with or without troops or on field service, Rs. 2 per diem (inclusive of horse allowance).

(d). Passage by road, rail, or steamer as at present; except that first class Assistant Surgeons be allowed two servants, and three maunds of baggage.

(e). Allowance for Medical Store Depots as at present.

(f). Detention allowance to Warrant and Commissioned Officers when attending Court-Martial at out-stations and during short stays, less than 20 days, as given to members of other departments.

Quarters.—On this subject much heart-burning and worry have been experienced, and some injustice done.

It is well known that officers and subordinates of the Military Works Department consider that quarters for Assistant Surgeons being free, they can be housed anywhere, so long as they get the authorised space. Witness Allahabad, Delhi, Meerut and Pindi, where Assistant Surgeons are located in the same building as venereal patients. In the last-named station an elephant shed in the R. A. lines some distance from the hospital, was converted into two sets of quarters for third class Assistant Surgeons. Again in most of the Murree Gullies and in Chitral, every one entitled to Government quarters is well housed, except Assistant Surgeons, who are supplied with tents.

I think rent should be paid for Government quarters at the rate laid down in para. 174, Budget Barrack Regulations for Warrant and Commissioned Officers of other Departments as follows :—

Rank.	Rate per mensem.		
1st and 2nd class Assistant Surgeons	12	0	0
Surgeon-Lieutenants ...	24	0	0
Surgeon-Captains ...	30	0	0
Surgeon-Majors ...	50	0	0

Camp equipage on line of march, in camps or on field service, free.

WAR, BOMBAY.

It has been generally acknowledged that the Department is very short-handed, hence a considerable increase in the numbers is most urgently needed.

The present war reserve of 20%, and 15% reserve on account of leave and sickness, is, I think, sufficient to meet requirements.

The war reserve to be kept in civil employ, but the present system of selecting officers for civil posts requires careful revising, as a glance at the Army List will show.

All officers in civil work should be seconded, and temporary promotions made in their place.

Yours &c., SENIOR ASSISTANT SURGEON.

—:O:—

ERRORS IN THE SANITARY ADMINISTRATION IN INDIA.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Now is the appointed time, the supreme moment, to press home to the Government of India, the need of sanitary reform throughout the land. If ever there was a disease which has been fought successfully by modern hygiene, it is plague. Sindh only shows it too plainly as well as Poona and Bombay. Thanks to Sir ANTHONY McDONNELL, who is a thorough sanitarian at heart, and possesses an enviable knowledge of State Medicine, the North-West Provinces have been kept free from the epidemic, although two attempts have been made by this fell disease to obtain a footing. We are aware unfortunately of the history of recrudescence in Poona and Bombay, mainly owing to a relaxation of sanitary measures after a false abatement for a small period. Had sanitary measures been carried on vigorously as they were at one time, for at least six months after the entire cessation of the disease, we would not now be in the dire predicament of being at our wit's end. What is required now is not fault-finding, although there is great room for it, but a complete change in the whole of the sanitary department. Hitherto Civil Surgeons have been ex-officio Health Officers in addition to their other multifarious duties. Work has been done in a very cursory and half-hearted way, especially where a large private practice has to be attended to. Dr. BAILEY, in his report on Poona, condemns the sanitation of the city in scathing terms. Might I enquire whose

that is to say, the public health is not either not paid any attention to their legitimate duties, or have been under the impression that the Health Officer of a town was not one of their principal cares. And this will continue while the system of private practice is allowed to Government doctors. The salary from Government is added to these men, and their only desire is how to amass money from private enterprise. The Government of India, following the lead of other civilized Governments throughout the world in this respect, never undertook the provision of medical aid for India into its own hands. It established medical Colleges and Schools where doctors could be trained, thence to be dispersed throughout the population. This is the way to supply the need. Independent Englishmen and other European medical practitioners have also settled in goodly numbers in India, to follow their avocation. But this privilege of private practice to State-paid doctors has so far entirely prohibited the development of the noblest of professions. We have no eminent scientists, we have not made any important discovery in medical science, although we have held India for over a hundred years. Diseases special to India are studied for us in Europe, and we sit quietly at home drawing our salaries, and thinking of the time when we can comfortably enjoy our pensions in suburban villas in London, however little we might have done to earn them. The pages of the *Lancet* or *British Medical Journal* may now and then be glanced over, but a microscope is seldom manipulated by us. Some of us don't know how to use it, although "Carpenter" may adorn our shelves. It is too much trouble to use it, or to learn its use after the practice of the day is over. I say the time for this happy-go-lucky system is past. The Government must get the worth of its money by making Civil Surgeons directly responsible to the Sanitary Commissioner in all questions of State Medicine, and appoint separate Health Officers for all the larger towns. Speaking for the North-Western Provinces, I would advise the employment of separate Health Officers for the towns of Allahabad, Lucknow, Cawnpore, Benares, and Agra at once. In the smaller towns, the Civil Surgeons must be made to visit each street and lane daily and report to the Chairman of the Municipal Board every morning on printed forms the prevalent diseases, sanitary suggestions, together with the births and deaths registered. Private practice must be entirely stopped; the Indian Medical Association guaranteeing to provide a medical practitioner for every station where the Government doctor is prohibited from practice.

We are not doing our plain and simple duty to India, and if we do not care for the censure of other nations in this respect, there ought to be some awakening in our inward consciences, some self-examination, some self-condemnation to prove to us that this official monopoly may enrich a few but is not fair dealing, for it is absolutely cruel to India. God never destined England to conquer India for the purpose of dishonestly administering its affairs.

Yours &c., BARRINGTON.

BOMBAY, 2nd February 1902.

THE WAR RESERVE OF ASSISTANT SURGEONS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—The following is a restatement of the Government Resolution on the decision to extend the system of forming a "War Reserve" of Military Assistant Surgeons for the British Army in India:—

With the view of creating an adequate War Reserve of Military Assistant Surgeons, the Government of India has decided to extend the employment of such officers in the Civil Department. The scheme has for its objects an extension of the present system under which Military Assistant Surgeons are employed in the Civil Department in time of peace, their services being available, on emergency, for Military duty or active employment in the field. Arrangements have accordingly been made to reserve a certain number of civil appointments under the several local Governments and administrations for Military Assistant Surgeons. It was further considered desirable to reserve certain appointments on State Railways, and, with the consent of the Companies, on Guaranteed Railways as well. Certain Local Governments and Administrations controlling railways were accordingly asked to co-operate in the scheme, and the question of applying the scheme to State Railways under the Director-General of Railways, was considered in the Public Works Department. It has now been agreed, with the concurrence of the Railway Companies, as regards Companies' Railways, that the appointments below should be reserved for Military Assistant Surgeons. In reserving these appointments, both on State and Companies' Lines, it has been laid down that the rights of present incumbents are to be duly observed, that is, the appointments of present incumbents will not be interfered with, and Railway authorities will be asked to employ Reserve Officers, within the number accepted, only as vacancies occur in their sanctioned establishments. It has been further decided that Railway Companies shall not be liable for pension contributions on account of Military Assistant Surgeons, but under orders. They will be required to pay their full salaries and to contribute towards their leave allowances, according to the Rule of Proportions (Article 56, Civil Service Regulations). The rate of pay drawn by the several grades of Military Assistant Surgeons is as follows:—

	Rs.
Senior Assistant Surgeons, with the Honorary rank of Surgeon-Captain	400
Senior Assistant Surgeons, with the Honorary rank of Surgeon-Lieutenant	300
Assistant Surgeon, 1st class, above 5 years' service	200
Do. do. do. below 5 do.	180
Do. do. 2nd class, above 5 do.	120
Do. do. do. below 5 do.	85
Do. do. 3rd class, below 5 do.	50
with rations, or Rs. 10 extra in lieu.	

The following appointments have been reserved for Military Assistant Surgeons on Railways:—

STATE RAILWAYS	No.	Pay.
North-Western	1	300
	2	200 each.
	1	180
	1	100
Eastern Bengal	1	400
	4	300 each.
	1	100
Oudh and Rohilkhand	1	300
East Coast	1	300
	1	125
Bombay-Madras	1	300

SCHEDULED WAGES OF CONTRACTORS.

Engineers-Madras	...	4	100 each.
Bengal and North Western	...	3	110
	rising to Rs. 150 each.
Indian Medical	...	1	150
	...	1	100
Southern Maharashtra	...	1	80
Bengal-Nagpore	...	3	200 each.
	...	1	150

Such is the scheme. It gives 30 civil posts, some good, some indifferent, and some bad, to Military Assistant Surgeons, and for these favors we give our thanks to Government.

Yours, &c., 30 YEARS A MILITARY ASSISTANT SURGEON.

CIVIL MEDICAL ADMINISTRATION IN THE
N.-W. P. AND OUDH.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—The letter which appeared in your issue of the 1st February 1898, under the heading "Civil Medical Administration in the Punjab," applies with equal, if not greater, force to the N. W. P. and Oudh, the Bengal Presidency, and the Central Provinces; as *ekhas*, the cheapest wheeled conveyances procurable on hire, are not as readily obtained in them as in the Punjab; and district tours at speed are consequently more expensive.

In the column "Comments and News" in the same issue under the heading "Sanitary Advance in India," you notice that the Government of the N.-W. P. and Oudh have marked the year 1897 by a new departure in sanitation, in re-constructing the Sanitary Board, which, when the affairs of a district are under discussion, will be aided in their deliberation by the District Magistrate, the Civil Surgeon, the District Engineer, and a delegate from the District Board.

The Lieutenant-Governor of the N.-W. P. and Oudh, can hardly be aware that the Civil Surgeons of twelve of the districts under his rule are under the recent interpretation of Article 109b, C. S. B., required to prosecute sanitary enquiries in their districts, practically at their own expense (i.e.) at a mileage of 4 annas, while in the same districts, all the other officials concerned, including the District Surveyor, or District Engineer, go over the same ground at a mileage rate of 8 annas. This is expecting too much from Civil Surgeons so situated, be they ever so keen on sanitation!

Though Civil Surgeons serving in provinces other than the Punjab are not tied down to an absence of only seventy-two hours from their jails, they are expected to perform their dispensary inspections in as short a time as possible, and are not infrequently required to explain why they halted for twenty-four hours at a dispensary. It is well understood that such enquiries emanate not from the Inspector-General, but from their native clerks; yet an enquiry, signed by an Inspector-General, necessitates an explanatory reply, followed by avoidance of a halt, however necessary at future inspections. With such factors at work, it becomes impossible for a Civil Surgeon, drawing travelling allowance at second class rates, to satisfactorily perform the inspection duties of his office,

and imperfect inspections must supersede work by the subordinates of the department which he superintends.

His Honor the Lieutenant-Governor of the N.-W. P. and Oudh, has apparently the interests of all under his rule at heart, and if it were possible in bringing this matter to his knowledge, it is more than probable that he would look into it, and cause such action to be taken as would remove what cannot but be considered an injustice to a very useful class of public servants.

Yours &c., "INTERVIEWED."

(We earnestly commend these remarks to the consideration of the Inspector-General of Civil Hospitals, N.-W. P. and Oudh.—Ed., I.M.R.)

————— 10: —————

GOVERNMENT DOCTORS AND PRIVATE
MEDICAL PRACTICE.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—However unhappy the present incumbents of State medical appointments in Calcutta, Madras and Bombay may be, at the straight and hard hitting which the *Record* has for years been dealing at the unfair monopoly of private practice by State-paid doctors, there can be no question of a doubt that not only the public, but the Indian Medical Service at large, will gain by the projected reforms that are shortly to be made in this connection. For example, one reform which the *Record* advocated six years ago, will soon be a *fait accompli*, namely:—All hospital posts in our big metropolitan cities, which used to be life-term appointments (or rather held till retirement) are now to be made *four* year "jobs." Instead of having a single good McLEOD or a HARVEY, or a McCONNELL, this plan will give us a dozen McLEODs, HARVEYS, and McCONNELLS, turned out of our big colleges with a rich fund of hospital experience, ready to work for the public good in many parts of the country. There will be no "monopoly of talent" in big cities; it will be found everywhere. So that much good is about to result from the persistent battering at the stronghold of "I. M. S. monopolies."

Then, again, we find the head doctor of the Calcutta General Hospital prohibited from engaging any further in private practice. We find, too, that the resident medical officers of the College and General Hospitals (all I. M. S. men) have also been interdicted, and we find Surgeon-Colonel BOMFORD, M.D., the worthy Principal of the Calcutta Medical College, absolutely resigning the privilege he is permitted to enjoy, of engaging in purely consultative practice, thereby setting a praiseworthy example to every medical officer in Calcutta who draws a State salary for the responsibility of attending the sick in our public hospitals, and for fostering and advancing the all-absorbing cares of training the medical youths of India. Truly we are on the eve of great and much needed changes, but the battle for reform is not yet ended, the victory for India is not yet won. "Coming events cast their shadows before them," and so these impending changes promise an occasion for congratulation, for encouragement and for greater union and for the tempestuous rallying of our forces till victory is ours, and India has gained complete redress for the wrongs that blot her medical ecotcheon.

Yours &c., A. LANGRISH IN THE VINEYARD.

HOOCUS DIPLOMAS AND UNCONTROLLED MEDICAL EDUCATION IN INDIA.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—One of the most gigantic evils haunting in the near future, and one which, if not grappled with in double quick time and with an iron hand, is sure to do incalculable mischief, is the question of uncontrolled mushroom medical colleges, which threaten to beat all previous attempts in the art of manufacturing ill-trained practitioners armed with loud-sounding titles and diplomas. The Medical Administration of Bengal and the Director-General at the head of all things medical, will not be able to plead the excuse that clear notes of warning were not sounded about this terrible evil. Calcutta has been plagued with one such syndicate styling itself "THE COLLEGE OF PHYSICIANS AND SURGEONS OF BENGLA," a more hocus-focus concern than which could not be conceived. Yet it has been deluding half-educated Bengali youths in dozens to its unfurnished shelter, and there after a few years of "attendance" on the jabberings of some self-constituted "lecturers." (?) they will be turned out *diplomaed*. The question of permitting such tomfoolery to continue is not a serious one, so long as a few unemployed medical men choose to spend or waste the leisure which apparently presses so heavily on their care, in playing at anatomy, physiology, and the whole list of the allied sciences. But when it comes to having these chatter-boxes assume the rôle of "Physician and Surgeon Manufacturers," then it is high time for the profession, the public and the State to demand that this dangerous *tamasha* should stop. It is marvellous to analyse the details of the qualifications of some of these "lecturers." One assumes the garb of general back-biter and scandal-monger and now caps these malefactions by Gospel preaching and Bible thumping! Surely such incongruities are evidence of a *very wide* knowledge of the art of "lecturing"!!

Yours &c., NO CRIMSHANKING.

MILITARY ASSISTANT SURGEONS' SERVICE.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—As the Council of the Indian Medical Association, in view of the official intimation received by it, will now probably move the Government of India for the early carrying out of reforms for the Military Assistant Surgeons' Service, I beg to state briefly the suggested reforms that will, in all probability, find acceptance with those in authority. It is best not to ask for too much in the present financial difficulties of the country. Therefore my suggestions will be as modest and as moderate as possible, having due regard to circumstances.

- (1) The abolition of the lowest or third class, and a salary of Rs. 100 on passing out of college.
- (2) Promotion after 5 years' service in each grade.
- (3) The abolition of the term *Subordinate* as applied to the service, and the designation "Indian Medical Department" to be substituted instead of I. S. M. D.
- (4) The abolition of the terms Senior Assistant Surgeon to our commissioned grades, the honorary designations of Surgeon-Major, Surgeon-Captain and Surgeon-Lieutenant standing alone, without the additional B.A.S. appended to them

These changes will cost very little to the State, but they will afford satisfaction to the service and bring contentment to the minds and hearts of all the men. As a *quid pro quo*, the Government might demand a higher educational standard, by insisting on candidates being possessed of Matriculation or Entrance Certificates from our Indian Universities, and that they shall undergo *five* years' medical training instead of four at college.

Yours &c., SENIOR MILITARY ASSISTANT SURGEON.

(The Council will take action in this matter as also in the matter of the Military Hospital Assistants at a very early date, but it behoves all members of these classes to enrol themselves on the list of the Association at once.—Ed., I. M. R.)

THE MILITARY LOCAL MEDICAL SERVICES LEFT OUT IN THE COLD.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—While all Military Hospital Assistants and Military Assistant Surgeons will congratulate their civil brethren on the promised reforms which the Government has notified to the Council of the Indian Medical Association it is about to confer on their departments, they will not feel their disappointment and disheartenment the less in view of this favor shown to their Civil confrères. We shall not complain of their good luck. We only hope and pray they will receive the *substance* and not the *shadow* of reform and redress.

However, as a Military Hospital Assistant, I feel that no time should be lost by my class to place a complete statement of our grievances before the Council of the Indian Medical Association, in view to their being immediately embodied in an appeal from the Council to the Indian Government. Clearly our position is not quite understood by the Council, and they need enlightenment as to our wants. Should we write direct to the Secretary of the Indian Medical Association, or should we place our case first in the hands of Mr. PHILIP, the representative of the Hospital Assistant class on the Council? That something should be done at once is very clear. What should be done is another matter, can you inform us of the best course to adopt, Mr. Editor?

Yours &c., MILITARY HOSPITAL ASSISTANT.

(It would be as well at this juncture if a special appeal on behalf of the Military Hospital Assistant class were made to Government by the Council of the Indian Medical Association, and we feel sure the Council would be glad to receive the fullest possible information on all points regarding the grievances and hardships of this class, either through Mr. PHILIP or direct through the Secretary. Let every Military Hospital Assistant immediately join the Indian Medical Association and thus give greater effect to the prayer of the Council to the Government.—Ed., I. M. R.)

HIGHLY PLACED ANGLO-INDIANS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Here are a few more names for your Anglo-Indian List:—

The Hon'ble Mr. J. G. Coleman, partner in the great firm of Spencer & Co., Madras, was Member of the Governor's Council there.

Surgeon-Major J. H. Sylvester, Professor of Ophthalmic Medicine and Surgery and Comparative Anatomy, Grant Medical College, Bombay.

Mr. Waite, Chief Accountant, Bombay Municipality.

Dr. T. J. Waite, L.M.S. his brother, occupies a prominent official position in Calcutta as Judicial Secretary to the Lord Chief Justice.

Yours &c., RECORDER.

YOUNG & CO., AN INDIAN CHEMICAL EXPERT.

(This means automatic coverage. It may mean for Wilson-Campbell to kindly submit a detailed statement of payments to the W. M. C. Provident Fund by each individual subscriber, and a further detailed statement of expenditures, so as to justify the treatment balance in the fund and in hand. Therefore some it is a simple matter to automatically discontinue the W. M. C. Fund while the L. M. C. Provident Fund and the L. M. C. are in operation. The L. M. C. will be able to handle all the business of the L. M. C. and will be able to handle the submission of these reports.)

(Mr. J. M. N.)

Surg.-Lieut. J. O. Robertson, M.B., O.M., I.M.S., has been placed on plague duty at Satara from 17th Jany. 1898.

CENTRAL PROVINCES GOVERNMENT.

Amt. Surgn. Madhu Sudan Motra to the civil medical charge Poona dist., from 18th Oct. 1897.

Amt. Surgn. Motiyamath Byack to do plague duty at Khajuraho from 9th ultimo.

Amt. Surgn. Nani Lal Pramanic was placed on famine duty, Saugor, from 15th Sept. 1897.

Amt. Surgn. Pramatha Nath Moskerji was placed on famine duty, Raipur, from 11th Sept. 1897.

Amt. Surgn. Hemchandra Biswas, doing duty under Civil Surgn., Nagpur, is deputed on Plague duty at Itard Honabhabad dist., from 6th Nov. last.

Amt. Surgn. Ganda Mal, on plague duty at Jabulpore, to do plague duty at Barhanpur, Nimar dist., from 21st Dec. 1897.

Hosp. Asst. Sobharam, on plague duty Gadawara Ry. Stn., Narsinghpur dist., is deputed on special duty at the Barmhan Fair.

Hosp. Asst. Bihari Lal is temply. apptd. to the Central Jail Hosp., Jabulpore.

Hosp. Asst. Lachhman Perahad, Lehara Poor-house, Saugor, from 12th Sept. to 2nd Oct. 1897.

N.-W. P. AND OUDH GOVERNMENT.

Amt. Surgn. Mohini Mohan Chatterjee, from Sadar Dispy., Ballia, to plague duty at Hardwar, Saharanpur dist.

Amt. Surgn. Gopal Chandra Gupta, Khurja Dispy., Bulandshahr, to plague duty at Hardwar, Saharanpur dist.

Hosp. Asst. Kalka Pershad, from Zamania Branch Dispy., Ghazipur, to Sadar Dispy., Ballia.

Hosp. Asst. Nanak Chand, from Chandaui Dispy., Moradabad, to Khurja Dispy., Bulandshahr.

Amt. Surgn. Ghulam Mustafa, Sadar Dispy., Mainpuri to Algaib on plague duty.

Amt. Surgn. Charu Charan Ghose, from plague duty, Aligarh, to Hardwar, Saharanpur dist.

Hosp. Asst. Baldeo Pershad, Shekohabad Branch Dispy., to Sadar Dispy., Mainpuri.

Amt. Surgn. Chanan Singh, on Reserve duty at Saharanpur, to plague duty at that station.

BURMA GOVERNMENT.

Hosp. Asst. Kein Ram assumed charge Police Hosp., Shwabo, 25th Dec. 1897.

Hosp. Asst. Anant Singh assumed charge Civil Hosp., Letpadan, Tharrawaddy dist., 4th Jan. 1898.

Hosp. Asst. J. Maslamoney, to Zigon, Tharrawaddy dist., to give evidence before the Subdiv. Magistrate, 6th Jan. 1898.

Hosp. Asst. J. Maslamoney assumed charge Jail Hosp., Tongoo, 14th Jan. 1898.

Hosp. Asst. Maung Tun U assumed charge Police Hosp. Finka, Mogang sub div., 18th Dec. 1897.

ASSAM GOVERNMENT.

Hosp. Asst. Syed Gyan Uddin, a supy. in the Sylhet dist., to the Goalpara dist., a supy. for duty under Civil Surgn. from 18th Jan. 1898.

Hosp. Asst. Srinath Das is apptd. a supy. for duty under Civil Surgn., Khasi and Jaintia Hill dist., from 20th Jan. 1898.

Hosp. Asst. Durga Gati De, Purnagudam Dispy. Nowgong dist., to Silhegar dist., Kokilamukh coolie depot from 14th Jan. 1898.

DOMESTIC OCCURRENCES.

The charge for inserting a Domestic Occurrence is Rs. 1 for subscribers and Rs. 2 for non-subscribers, which should be forwarded in stamps with the announcement.

BIRTHS.

WILLIAMS.—On 6th Jan., at Tayside, Broughty Ferry, N. B., the wife of Surgn.-Capt. C. E. Williams, I. M. S., of a daughter.

WATSON.—On 11th Jan., at Hendre, Overton-park, Cheltenham, the wife of Deputy Surgn.-Genl. George Alder Watson, Bengal Army (retired), of a son.

YOUNG.—On the 28th Jan. 1898, at Bareilly, N.-W. P., the wife of Surgn.-Capt. W. Young, M.A., Indian Medical Service, of a daughter.

WHITELAW.—On the 7th Feby. at 1, Larkin's Lane, Calcutta, the wife of Dr. B. Whitelaw, of a son.

MARRIAGE.

BUCHANAN—HUSBAND.—On the 28th Jan. 1898, at Ajmere, by the Rev. William Bobb, M.A., and Rev. James Gray, John Buchanan, Allahabad Bank, Bareilly, youngest son of Rev. James Buchanan, Foreign Mission Secretary, United Presbyterian Church, Scotland, to Eliza Jane, elder daughter of Rev. John Husband, F.R.C.S. N., C.I.M., Ajmere.

NOTICES TO CORRESPONDENTS.

R. J. O. (Bina).—Refer the matter of your lost certificate to the P. O. authorities. Should you fail to get it, address the Secretary officially, and on payment of two rupees a duplicate certificate will be prepared for you.

Senior.—Some of your suggestions are too retrograde and would do infinite harm to the service, so we could not dare to give publicity to them.

R. S. P.—Your case is well reported, but it is a very simple one of gastro-intestinal symptoms resembling catarrhal irritation, due to the presence of worms. As such, it is a very common ailment. We shall be glad to have you report a series of such cases with the most effectual therapeutic treatment.

A. S. (Lahore).—Your interesting report will appear in our next number.

A. N. E. P. (Rangoon).—We commend your ambitious aspiration and wish you success. You will find all the latest information you need in the new edition of the *Medical Register and Directory of the Indian Empire* which will be published shortly.

Dr. H. A. Macleod, M. B. (Saharanpur) writes:—"Can you give me therapeutics of 'phulooa,' as obtained from *paharia*." Will some one skilled in the therapy of Indian drugs kindly answer Dr. Macleod in the *Record*?

N. H. (Chandpur).—We consider the female hospital assistant who attended your wife, more than fully entitled to the charges she has made for medical attendance and travelling allowance. You would do a graceful and just act to meet her account without demur.

Subscribers (Allahabad) writes:—"Can you or any of your readers inform me whether there are any unconvicted medical appointments in the N.-W. P. and Oudh, and if there are, in what stations, and what is the scale of pay?"

L. F. (Madras).—The so-called College of Physicians and Surgeons in Calcutta, is a bogus Bengali scheme and not worthy of mention. Our answers referred to R. C. S. and R. C. P. of Great Britain, about which, full information can be gained from the *Medical Register and Directory of the Indian Empire*.

J. M. P. and T. R. N. (Madras).—Make out a clear statement of the grievances of your class and submit them to the Secretary, I. M. A., without delay.

J. L. B. (Bombay).—It is difficult to do as you ask just now.

N. B. (Sirdarpur).—Dr. J. Duke's promotion to a Surgeon-Colonelcy ought to be gazetted almost immediately.

Mahar Bhil Corps.—Hospital Assistants who can fulfil the educational and professional requirements of the British Corporations are as eligible for their diplomas as anyone else.

A. M. D.—We have already referred to the Maidstone Epidemic Medal.

D. L.—Your case is a hard one, and ought to be reconsidered by the Government.

Straits Settlements.—The question papers set by Dr. H. J. Gibbs are very good indeed.

V. V. C. (Multan).—Many thanks for your excellent suggestions.

E. J. A. (Dum-dum).—We appreciate your kindness in sending us the examination papers.

F. C. R. (Meen Meer).—We hope you will reconsider your letter; and write us again.

S. B. (Akola).—Read Dr. Giles' critique in the *Record*, S. D. (Simla).—We greatly sympathise with you, your case will be placed before the Association in due course.

W. W.—Next number.

The fact that the cause of malarial fevers without being struck by the depressing influence of the malarial poison.

Further I am wrong in saying "at one time," for evidence occasionally appears to show that in the minds of some, organic matter and malarial are still inseparably connected.

This theory that organic matter was the cause, or helped to produce the cause, of malarial fevers has received more wounds, and more mortal ones, than ever JULIUS CESAR did, yet it still lingers on, an illustration of the amazing vitality of popular beliefs. Truly, to slightly alter the quotation, "Custom doth make cowards of us all." We are loath to turn against and reject what has been handed down as gospel truth from generation to generation.

Yet, seriously, is there anything in this idea that is worthy of our consent?

In this, as in many other aspects of the malaria question, we encounter little but vacillation and vagueness of ideas, differences of opinion and shifting of position, one hypothesis abandoned after another, the absence of all accuracy of statement or clear reasoning, and of anything that can be called proof.

ANIMAL ORGANIC MATTER.

In former days decomposing animal matter was supposed to be a particularly virulent cause of malarial fevers, and a case will be found in the *London Medical Gazette*, Vol XXVIII, p. 790, when a severe epidemic of malarial fever followed an inundation of the sea at Lynn Regis in 1779, and where decaying fish were said to have been the cause.

In 1762 JAMES LIND, who wrote on "The Putrid and Remittent marsh fever of Bengal" (not to be confounded by the way with his relative JAMES LIND of Haclar, author of the "Essay on Diseases Incidental to Europeans in Hot Climates"), disputed this idea which was at that time generally believed, and brought forward many convincing arguments to prove that decaying animal matter had nothing whatever to do with the causation of malarial fevers.

This opinion has, of course, long been abandoned, and vegetable organic matter alone accused.

As early as 1820, WILLIAM FREDERSON¹ or FRASERSON (for his name occurs with both spellings) who contributed some very able articles on the subject, the result of large experience in malarious countries, strove in vain to dissipate this idea. "Putrefaction," he says, "and the matter of disease are altogether distinct and independent elements."

He was able, moreover, to bring forward some very apposite illustrations in support of his contention.

"The town of Point au Pitre, Guadeloupe," he tells us, is situated around some of the most putrid marshes in the world, the stench is never absent from the streets,

and it is not surprising that the malarial fever is frequent in this town. The marshes are very low, where the stagnant and putrid water is very offensive; yet at Fort Flory d'Arce, the malarial fever is not the prevailing ailment, which is very curious, as the appearance of some stagnant water in this water on the surface, no small, yet it is very distant from malarial fevers."

"In this malarious island of Tobago" he also tells us, "the chief fort and barracks were situated half a mile to leeward of the Bacolette swamps, from which a strong ammoniacal stench frequently pervaded the barracks. Yet the troops here are freer from malarial fevers than any other in the West Indies."

Needless to say, FRASERSON was listened to with a sort of good-natured contempt, he was suspected to be having a hobby and riding it too hard; his ideas were not refuted; they were not considered worthy of so much attention; they were simply ignored.

In 1856, in the *Indian Annals of Medicine*, we see MCKINNON expressing the same opinions, in his experiences of the Indigo factories of Bengal, observation forced the fact upon his attention. "The amount of decomposing matter," he says, "in all stages of decay, now swamped with rain, now exposed to a blazing sun, is immense; yet after much inquiry I have never discovered that fever has been the consequence."

LIVINGSTON² remarked the same thing on the Zambesi, that the air laden with the most offensive smell from decomposing marshes was innocuous.

The idea, however, was too firmly rooted to be shaken by such testimony or by any testimony, no matter how convincing it might appear.

The history of malaria presents us with many ideas which seem to have been, and I may even say to be, received with a sort of superstitious veneration. Men believe by faith; those who have faith will not reason, and those who reason cannot believe.

In 1838, the prevailing opinion is thus expressed by HINCH. "Observers at the most diverse points of the globe are nearly unanimous in saying that the development of the malarial poison depends directly or indirectly upon the process of decomposition of organic and particularly of vegetable matter, in or upon the soil, and that it is in a measure bound up with these processes."

THE MALARIAL FACTORS.

It was a favorite exercise at one time to formulate the factors that were necessary for the production of malaria. Some were satisfied with three: heat, moisture, and decomposing vegetable matter.

These were the factors of the older writers; then came TOMMARI-CHUDDELL also with three factors, but with a notable variation, he admitted organic matter; his three factors were (1) very high temperatures, not below 20°C; (2) persistent humidity; (3) access of air to the moist strata.

In the 1891 edition of PARKES'S "Practical Hygiene" four factors appear: (1) Heat of soil (which must reach a certain point, equal to isotherm 45° F of summer air temperature); it has always puzzled me to understand why

(1). Trans. Medico-Chir. Soc. Lond. 1820, 1821, 1822, 1823, 1824, 1825, 1826, 1827, 1828, 1829, 1830, 1831, 1832, 1833, 1834, 1835, 1836, 1837, 1838, 1839, 1840, 1841, 1842, 1843, 1844, 1845, 1846, 1847, 1848, 1849, 1850, 1851, 1852, 1853, 1854, 1855, 1856, 1857, 1858, 1859, 1860, 1861, 1862, 1863, 1864, 1865, 1866, 1867, 1868, 1869, 1870, 1871, 1872, 1873, 1874, 1875, 1876, 1877, 1878, 1879, 1880, 1881, 1882, 1883, 1884, 1885, 1886, 1887, 1888, 1889, 1890, 1891, 1892, 1893, 1894, 1895, 1896, 1897, 1898, 1899, 1900, 1901, 1902, 1903, 1904, 1905, 1906, 1907, 1908, 1909, 1910, 1911, 1912, 1913, 1914, 1915, 1916, 1917, 1918, 1919, 1920, 1921, 1922, 1923, 1924, 1925, 1926, 1927, 1928, 1929, 1930, 1931, 1932, 1933, 1934, 1935, 1936, 1937, 1938, 1939, 1940, 1941, 1942, 1943, 1944, 1945, 1946, 1947, 1948, 1949, 1950, 1951, 1952, 1953, 1954, 1955, 1956, 1957, 1958, 1959, 1960, 1961, 1962, 1963, 1964, 1965, 1966, 1967, 1968, 1969, 1970, 1971, 1972, 1973, 1974, 1975, 1976, 1977, 1978, 1979, 1980, 1981, 1982, 1983, 3271, 3272, 3273, 3274, 3275, 3276, 3277, 3278, 3279, 3280, 3281, 3282, 3283, 3284, 3285, 3286, 3287, 3288, 3289, 3290, 3291, 3292, 3293, 3294, 3295, 3296, 3297, 3298, 3299, 3300, 3301, 3302, 3303, 3304, 3305, 3306, 3307, 3308, 3309, 3310, 3311, 3312, 3313, 3314, 3315, 3316, 3317, 3318, 3319, 3320, 3321, 3322, 3323, 3324, 3325, 3326, 3327, 3328, 3329, 3330, 3331, 3332, 3333, 3334, 3335, 3336, 3337, 3338, 3339, 3340, 3341, 3342, 3343, 3344, 3345, 3346, 3347, 3348, 3349, 3350, 3351, 3352, 3353, 3354, 3355, 3356, 3357, 3358, 3359, 3360, 3361, 3362, 3363, 3364, 3365, 3366, 3367, 3368, 3369, 3370, 3371, 3372, 3373, 3374, 3375, 3376, 3377, 3378, 3379, 3380, 3381, 3382, 3383, 3384, 3385, 3386, 3387, 3388, 3389, 3390, 3391, 3392, 3393, 3394, 3395, 3396, 3397, 3398, 3399, 3400, 3401, 3402, 3403, 3404, 3405, 3406, 3407, 3408, 3409, 3410, 3411, 3412, 3413, 3414, 3415, 3416, 3417, 3418, 3419, 3420, 3421, 3422, 3423, 3424, 3425, 3426, 3427, 3428, 3429, 3430, 3431, 3432, 3433, 3434, 3435, 3436, 3437, 3438, 3439, 3440, 3441, 3442, 3443, 3444, 3445, 3446, 3447, 3448, 3449, 3450, 3451, 3452, 3453, 3454, 3455, 3456, 3457, 3458, 3459, 3460, 3461, 3462, 3463, 3464, 3465, 3466, 3467, 3468, 3469, 3470, 3471, 3472, 3473, 3474, 3475, 3476, 3477, 3478, 3479, 3480, 3481, 3482, 3483, 3484, 3485, 3486, 3487, 3488, 3489, 3490, 3491, 3492, 3493, 3494, 3495, 3496, 3497, 3498, 3499, 3500, 3501, 3502, 3503, 3504, 3505, 3506, 3507, 350

is made an "unfavorable air temperature," but "to moisture, (2) air, (3) moisture, (4) some impurity of soil which is not probably is of vegetable nature."

In this way these poor factors have been shuffled, and dished up over and over again in different ways, without making any one any the wiser or adding an iota to our knowledge of the subject.

The omission of organic matter by TOMMASI-CRUDELI as an essential in the production of malaria was a very curious one. It will be remembered that between the years 1879 and 1886 the subject of malaria occupied a very prominent place in the attention of the medical and scientific world, owing to the announcement of the KLEBS and TOMMASI-CRUDELI bacillus, and the enterprise and energy of the latter in pushing its claims.

This period is a remarkable one in the history of malarial literature; the name of TOMMASI-CRUDELI dominated everywhere. He published a large number of writings containing statements opposed to the commonest physical laws of nature. Yet no one contradicted him and his bacillus was received everywhere with open arms.

In the 1888 edition of PARKES four years after the discovery, we find the following statement under paroxysmal fevers.

"*External cause.*"—"This was presumed to be putrescent, or at any rate decomposing vegetable matter, derived from a moist and putrescent soil, which was carried into the body by the medium of water or of air. But the later views of KLEBS and TOMMASI-CRUDELI attribute it to a low organism of the nature of bacillus, to which they have given the name *Bacillus Malarie*."

The readiness with which this bacillus was received proves conclusively the unsatisfactory nature of the views held up to that time, had they possessed any substantiality, or had they rested upon any satisfactory foundation, men would not have parted with them so easily.

So vague and shadowy were all those theories of miasms, of subtle, imponderable fluids, etc., that they vanished before the attack of an imaginary bacillus.

TOMMASI-CRUDELI may be said to have reached his climax at the International Medical Congress, held at Copenhagen in 1884. Soon after that he and his theories "fell like Lucifer never to rise again;" "then followed a blank, men were ashamed of themselves for their ready credence, and the whole subject was neglected for several years.

On the supposition that malarial fevers are caused by decaying vegetable matter, the conclusion is easily arrived at that where there was most decaying vegetable matter, there should be most fever and vice versa, and DRAKE¹ has actually laid down this rule for us. He says:—

"It is a safe generalization to affirm, that all other circumstances being equal, autumnal fevers prevail most where organic matter is greatest, and least where it is least.

To show how unequal the other circumstances must have been, it is only necessary to quote the observations made by STANLEY on the Congo and a few other examples. I may be wrong, but I have always looked upon

STANLEY's Congo experiences as of particular interest and value. They give us data which we do not easily find elsewhere. They present us with a vivid picture of a great river rolling through one of the most malarious parts of the world with stations dotted here and there along its course, occupied by Europeans.

They are the records of a shrewd and observant traveller, but they are more than this; they are the notes taken by men of the habits of their deadliest enemy; for fever meant to him and his companions life or death, and success or failure to a great enterprise.

STANLEY¹ went to the Congo imbued with all the teachings of the miasmatic doctrine, with a wholesome dread of marshes, organic matter and deadly exhalations from the soil. He, accordingly, whenever it was possible, selected sites for his stations as far removed from such conditions as he could. The result may be told in his own words.

"At Banana Point," he says, "and at Boma, in the midst of marshy exhalations, situate almost at the water's edge, the Europeans have enjoyed better health than at Vivi." Vivi, he describes as built on a dry rocky plateau about 340 feet above the river. "And remarkable for the absence of anything likely to vitiate the air from putrefying vegetation."

"At Kinshassa, just 10 feet above high water, better health has been enjoyed, indeed almost complete immunity from sickness, than at Leopoldville, five miles below situate 83 feet above the river level."

"At Equator Station, with the river only five feet below its foundations, creeks sable as ink surrounding it, the ground unctuous with black fat alluvium, Europeans enjoy better health than at Manyanga, 240 feet above the river and 1,100 above the sea."

The Congo is not exceptional in this respect; for BATES² tells us that swampy and weedy places are more healthy than dry one on the Amazons.

To any one even moderately acquainted with the literature of malaria, plenty of cases must occur where malaria has prevailed in its worst forms in the almost total absence of organic matter of any kind. Instances have been recorded from Holland, Spain,³ Portugal.⁴ The Ionian Isles (Vido), Sicily, Algiers, on the shores of the Persian Gulf described by EVATT,⁵ as "without rain, without rivers, without vegetation. HEYNE⁶ described malarial fevers as occurring on bare rocky hills in Southern India, In Sindh, KIRK attributed them to the influence of magnesian limestone in the absence of organic matter.

Hong-Kong was at one time notorious for such fevers, though its soil contained only 2 per cent. of organic matter; and the soil of Mean Meer, another very malarious place contains but 4.13 per cent.

Writing in 1888, HILTON FAGGE⁷ says:—"These exceptional cases are fatal to a hypothesis which at one time was generally upheld, namely, that the poison of ague is nothing more than a product of putrefying vegetable matter."

It must strike one as a very extraordinary thing that

an opinion that appears so obvious and irrefragable, had not forced itself upon the minds of all writers long before, but such was not the case, and even to the present day, judging from the rareness with which it is expressed, the opinion has not met with general acceptance.

In 1885, Surgeon-Major FLEMING¹ in a very able and interesting paper in which he describes a lengthened series of careful observations he made "with the intention of determining what relation the physical causes at work in Mean Meer bear to the prevalence of malarial fevers there," concludes with the remark that malaria is a product of continuous heat and moisture upon vegetable organic matter.

And the 1891 edition of PARKES, as we have seen, still gives its support to this view.

It was evident, however, even to its strongest supporters, that the idea had been severely shaken, and that it would have to be modified to bring it into harmony with observed facts, and to meet the serious objections alleged against it.

Surgeon-Major FLEMING, in the above-mentioned paper, gives us an inkling of what the modification is to be. "malarious soils," he says, "may be practically divided into two main kinds. The very dry and barren soils, usually sandy, and the very damp with luxuriant vegetation, partaking more or less of the nature of a swamp. Organic matter is common to them both, and in each case is found to be considerably in excess of the requirements of the vegetation found on the soil."

This, however, is not a classification or division of malarious soils practical or otherwise, it is simply a description of the extremes of a series, and an admission that malaria can prevail under such divergent conditions.

The chief point of interest about the above quotation is the idea that organic matter is only dangerous when it exists in the soil, *in excess of the requirements of the plant life of the place*. This is very ingenious; for it is an endeavour to explain why the small amount of organic matter found in the soil of Hong Kong and Mean Meer, and other dry barren places, is as poisonous as the much-larger proportion found in places where a rich and luxuriant vegetation exists.

M. COLIN² however, is the originator of this idea, he ascribes malaria to "*puissance végétative du sol*." "In my view," he says, "the fever is caused chiefly by the vegetative power of the soil whenever that power is not called into action, when it is not exhausted by plants sufficiently abundant to use it up."

He also admits that any soil can produce malaria if it is exposed to sufficient heat.

This hypothesis, which beyond its ingenuity has little to recommend it, appeared to open a way out of a difficult situation, and has been eagerly seized upon by some; but instead of proving a road to safety, it, by narrowing the issue, has turned into a mere *cul de sac*.

SMART³ in the "Medical History of the War of the Rebellion" tried to establish it on a satisfactory basis. "The poison of the disease," he tells us, "is elaborated during the reduction of nitrogenous organic matter into the inorganic form in which it is available for absorption by growing plants, and evolved from the surface as malaria,

when the living vegetation fails to absorb all the surplus of the prepared nutritive material."

SMART's intention is to state that, the evolution of malaria depends upon the amount of vegetation present; if the vegetation is sufficient to use up all the organic matter, there will be no malaria; but if the organic matter is in excess of what the plants can make use of, malaria will result.

Yet in the very sentence in which he tries to lay this down, he really makes the opposite statement, viz., that plant life can have no effect whatever on the elaboration of the malarial poison.

For he tells us that the plants cannot absorb the nutritive material until it has reached the inorganic state, while the poison is formed before this state is reached, while the transformation from organic to inorganic is going on. The poison of malaria is, in fact, elaborated at a time anterior to that at which the plant begins to act upon the organic matter.

He continues—if it is worth while to return to any more of his statements—"Free exposure to the effluvia from decomposing vegetable masses does not develop malarial affections, it is only when this vegetable matter has been mixed with soil and is undergoing the fermentative processes which result in the nitrification of organic ammonia that the presence of malaria is manifested."

"Malaria may therefore be considered due to a want of relation (what relation?) between the nutritive elements of the soil and its living vegetation."

From all this it follows that decomposing organic matter is only dangerous when mixed with soil; it is not the fermentative process that is dangerous for, of course this takes place in any case, a practical question is, if decomposing vegetable masses are ever free from a certain amount of admixture with soil? It is difficult to see how they can be. Smart however, seems to think otherwise and under such conditions he tells us they are harmless. It is the soil then that is the dangerous element, when it is mixed with decomposing vegetable matter and nitrification is going on.

Now it is a very curious thing that this very process of nitrification, which SMART considers so beneficial, is regarded by KELSON and KIMMER⁴ as playing a very important and beneficent rôle in the "assainissement" or making healthy of malarious places: "the soil is made healthy," they tell us, "by drainage, which not only withdraws the water from the soil, but admits the air necessary for the nitrification of organic matter."

It is hardly necessary to add that this process of nitrification is of the greatest importance in the chemistry of Nature, and that by it organic matter is reduced to the fittest state for absorption by plant life; it is presumably in the most highly cultivated land that this process attains its maximum, and to this end the efforts of the agriculturist are directed when he manures the soil; highly cultivated lands should, according to SMART, be the most malarious, and occupation of the agricultural labourer one of great danger. As everyone knows, such is the reverse of being the case.

In spite of all this MACLEOD in Quain's *Dictionary of Medicine*, 1894, gives some support to this idea.

1. A. M. D. Report, 1884.
2. Traité des Fièvres Intermittentes, 1861.
3. Fort III. Med. Vol. p. 157, 1865.

4. Maladies des Pays Chauds.

On page 780 of their *Traité des Maladies des Pays Chauds* in explaining the well-known phenomenon of malarial fevers appearing after inundations from rivers they say: "The effluvia given off from organic matters left on the slopes of the ditches and hillsides, when they were uncovered by the retching water, gave rise to an epidemic of intermittent fever."

On page 849 they say:—"The fever-causing agent is not formed by any product arising from the decomposition of the organic matters of the soil." Again, on the same page, "malaria does not necessarily arise from foci of decomposition, from which we may conclude that it is produced not by any direct product of vegetable decomposition but by a specific cause which finds amidst such surrounding, the most suitable conditions for its development."

On page 850 they say, talking of the conditions of the soil that are favorable to malaria:—"The conditions of the soil consist in its richness in organic vegetable matter, combined with permanent humidity," "the porosity, the richness in organic matter and the hygrometric condition are the important points. The most varied soils can give rise to the fever if they have on the surface, or in fissures deposits of humus periodically moistened."

And lastly, on page 878—"The most extensive sources of malarial exhalations on the surface of the globe are, as we have seen above, uncultivated lands rich in vegetable organic matter."

Now here is a theory which has been talked about, written about, argued about, alternately denounced and upheld for centuries, and after all this discussion, this is the wretched unconvincing contradictory state in which we find it at the hands of its ablest exponents.

They wish both to have their cake and eat it, in one place to bring forward organic matter as the cause and in another under a flimsy disguise to deny it.

Such a pronounced state of uncertainty and vacillation condemns the whole organic matter theory far more than any arguments of mine.

CONSERVATIVE SURGERY OF THE SPLEEN : A BLOODLESS METHOD OF PARTIAL EXCISION PERFORMED ON TWENTY-TWO DOGS WITH TWENTY-ONE RECOVERIES.*

By H. MARTYN JORDAN, F.R.C.S. Eng.

Late Teacher of Operative Surgery H. H. the Nizam's
Medical School, Hyderabad.

WHILE in India, my attention was attracted by the great number of people suffering from enlargement of the spleen and by the frequency with which cases of death from rupture of this organ were reported in the newspapers. The violence needed to rupture the spleen was often very

slight. A single blow with a walking stick, or even a kick with the heel of the shoe, would rupture the spleen, it might kick with the heel of the shoe, or even a kick with the heel of the shoe of a carriage going at a walking pace, etc., being sufficient in many cases. Palpation revealed a greatly varied condition of the organ. It was often tender and soft, in other cases painless, hard, and resistant. In size it varied considerably, and in speaking of the native of India one might almost say that it was normal for the spleen to extend from the eighth to the twelfth ribs, it being the exception to find the splenic dulness confined to our European limit, and in practice unless the edge could be felt below the margin of the ribs, the patient was regarded as having a normal spleen. In some cases the organ extended across the abdomen and the edge could be felt in the right iliac region—as in one of my servants, a dog boy, aged nine years—and it was not uncommon in these cases to see young boys and girls, and occasionally adults, walking about with the shoulders and head thrown back and the abdomen as prominent as in a six months' pregnancy. Between this extreme and the other, in which the edge came just below the margins of the ribs, there was every gradation in size. The enlargement of the spleen interfered greatly with the person's occupation, the sufferers being markedly lethargic and indolent, anemic, short-breathed, and often cyanosed, with but small power of endurance, and from the careful way in which they performed their work and walked through crowded streets, instinctively shrinking from any possibility of a contusion to the abdomen, it was obvious that they were always conscious of this enlargement.

In the majority of cases, and especially in the soft tender enlargements, the size of the spleen can be reduced very greatly and often brought back to nearly its original size by medicinal means—*e.g.*, the administration of a mixture of the sulphates of quinine, soda, and magnesium in full doses, but some of the hard, painless, chronic forms resist all medical treatment, and it is in these that surgery can be advantageously resorted to. These chronic hypertrophies are the cases where the total extirpation of the organ has been attended with most success, and this is the operation which has been and still is advocated in these cases. But before an organ be excised a fairly extensive knowledge of its functions should exist, or at least a knowledge of means by which the normal function may be artificially replaced, otherwise unfortunate results may accrue similar to those which obtained after the removal of the whole thyroid, results which were only checked by the observations and researches of SCHIFF, REVERDIN, KOCHER, VERNI-MORANDI, and others as to the effect of the total extirpation of the organ and for the relief of which we owe so much to the brilliant discovery of Dr. GEORGE MENKAY. I venture here to express the opinion that in the expected cases of successful splenectomy sufficient time had not elapsed between the operation and the report to justify an assumption that no ill-effects would accrue, and in connection with this I would point out the singularly few cases in which the blood has been examined before and after operation.

The functions of the spleen are unfortunately but imperfectly known. It is stated that the whole organ can be excised without affecting the individual surviving beyond a subsequent increase in size of the splenic vessels, which

*Reproduced from the *Lancet* by request.

this statement I am inclined to doubt. In a litter of four healthy pups one month old the whole spleen was excised in one, the half spleen in three, and the others were kept unoperated upon for comparison (at the time I had no haemocytometer, etc., for blood examination); one of the partial punctions died from shock, the other two made excellent recoveries and speedily grew big and fat, growing, as it happened somewhat faster than the un-punctured brother. The pup whose whole spleen had been removed remained fairly well for a short time, then gradually became emaciated and died from marasmus three weeks after operation, at which time its framework was distinctly smaller than that of the other three. In other cases where I excised the whole spleen (which, unfortunately, were operated upon only a short time before my departure from India and so did not permit of a sufficiently long supervision) the dogs suffered considerably from shock and were markedly quiet and apparently distressed for days afterwards and ate but little, conduct which was quite unlike that of the dogs upon whom other operations had been performed. Again, the following reports of splenectomies show that the condition of the blood is materially interfered with. VULPIUS¹ states that in eleven observations after splenectomy there was a more or less rapid and pronounced increase in the number of leucocytes. In MALIN's² case (extirpation for axial rotation on 2nd, January 1894) the examinations on the second and fifteenth days after operation showed the blood to be normal and the patient left the hospital on 25th January "in good general health." On April 23rd, there were 4,840,000 red and 80,000 white corpuscles per c.mm. (1 white to 161 red); 50 per cent. haemoglobin, and a fairly considerable number of large white nucleated corpuscles varying in diameter from 20 μ to 50 μ and in which were contained several red corpuscles—in some twenty or more—the red cells apparently undergoing disintegration. On 23rd May (nearly five months after operation) the red cells had decreased to 3,800,000, and the white increased to 50,000 (1 to 66), this being the last recorded note of the case.

That the spleen must have important functions is shown by (1) the intimate and unique way in which the blood is brought into contact with the spleen tissue; (2) the enlargement during digestion; (3) the large rhythmical contractions and expansions; (4) the large white cells in the pulp which contain more or less disintegrated red cells, or else are colored with haemoglobin; and (5) the differences between the blood brought to the spleen by the artery and that carried away by the vein, the proportion of white to red corpuscles being 1 to 2000 in the former and from 1 to 60 or 70 in the latter; the blood in the vein is also said to have a higher temperature and to contain smaller, brighter, less flattened red cells which do not form rouleaux and on which water has not the same destructive power that it has on the ordinary red cell, and it also contains an increased proportion of the products of oxidation or reduction as well as haemoglobin or its derivatives, free in the plasma. The spleen, therefore, must have a most important influence on the life-history of the red cell, probably being the chromatocium of untold millions of the

"used up" and the health resort of the inviolate. Again, from the great amount of lymphoid tissue in the organ—the great increase in the number of the white cells in the splenic vein, the increase of them in the general circulation in diseases of the spleen, the leucocytosis in fevers where the organ is also enlarged, and the increase following its irritation, it may be considered certain that the spleen is a great manufactory of the white cell.

These considerations impressed me with the great importance of leaving a portion of the spleen to fulfil its functions and led me to devise a method of partial excision, by which means the organ can be reduced sufficiently in size to ensure its being under the protection of the costal arch. In addition I hoped that such an operation might throw light upon the functions of the spleen and possibly upon some points in the etiology of malarial fever. It may be mentioned here that with the latter object in view in three cases the spleen was exposed and to irritate the organ, MORTON's fluid injected into its substance. This was done in conjunction with my friend Surgeon-Lieutenant-Colonel LAWRENCE, but beyond the fact that the dogs were very quiet with hot noses, accelerated pulse, and a possible slight increase of temperature for a couple of days, no result was obtained and the blood examinations were negative.

Anatomy.—The anatomy of the dog's spleen is very similar to that of the human being, the most marked difference being in its shape, which is more elongated, flatter, with a distinct depression or fissure running transversely from about midway along its anterior border. Its size varied considerably, chiefly with the size of the dog, but in a few cases it was fibroid; it was generally from 5 to 6 in. long, from 2 to 2½ in. broad, and nearly 1 in. thick. The splenic artery divides about 1½ to 2 in. from the spleen into branches (from four to eight in number) which spread out, like the ribs of a fan, to enter the hilus which extends lengthways along the inner surface of the spleen terminating a short distance from either end. The plenic artery often gives off a branch which supplies the upper extremity of the spleen.

The operation.—Under chloroform the abdomen and thorax were well washed and the left side was shaved and rendered as aseptic as possible. An oblique incision three inches long was made an inch below, and parallel to, the margin of the ribs. The spleen was brought gently out of the wound, lower end foremost, only as far as was necessary, the upper end not being exposed except in those cases where this was the end removed. A pair of SPENCER WELLS's forceps was applied to the lowest arterial branch where it entered the hilus; another pair of forceps was applied to the same artery about a quarter of an inch farther from the spleen; the tissues between these forceps were then divided with scissors and two more forceps applied, as before, to the next vessel. In this way the gastro-splenic omentum was divided without loss of blood, and without undue strain on the pedicle up to the level of the proposed division of the spleen (several arterial branches were left to supply the upper end which was to be retained). The forceps on the spleen-side of the divided gastro-splenic omentum were then laid along the inner surface of the lower end of the spleen, and an assistant raised this end and the forceps, so-

¹ *Medical Annual*, 1898. Reported by Major Roberts.
² *The Lancet*, Dec. 13th, Sept. 14th 1894, and quoted by Major Roberts in the *Medical Annual*, 1895.

that both surfaces of the spleen were well exposed. As the lower surface it was decided to divide the organ the blood-flow through it was arrested by a continuous ligature made in the following way: a long needle threaded with thirty coarse silk twist one and a half feet long was inserted on the inner or "under" surface about half an inch from the edge or border and passed through the thickness of the spleen, emerging on the outer or "upper" surface about the same distance from the edge; the ligature was drawn through until the ends were equal; the free end was then brought up round the border of the spleen and a "double turn" made with the two ends and drawn as tightly as possible, this "turn" being kept over the exit of the needle. The needle was then passed back through the spleen on the occluded side of the organ as close to the line of ligature as possible and an eighth of an inch to the "edge or border side" of the turn; this was done in order that the next loop should include the spleen where the needle had previously passed through, so that any oozing along this track should be stopped when the loop was drawn tight. The needle was then re-passed through the spleen from the under to the upper surface half an inch further on and a double turn again taken and drawn tight. Continuing in this way the breadth of the spleen was traversed. A reef-knot was then tied and the ends were cut short. The needle may be passed from the upper to the under surface and the turns made on the under surface, but the way described is the more convenient. The occluded end of the spleen was then cut through close to the line of ligature. Separate ligatures were tied round each portion of the gastro-splenic omentum included in the forceps, any tension on the pedicle being relieved as these were tightened.* The peritoneum and the three muscular coats were severally united with continuous sutures, the skin incision not being closed. The whole operation was completed in from fifteen to twenty minutes.

The points in the operation which I wish to emphasise are: 1. Its great facility, especially when the double turn is made by twisting the needle round the free end and so getting this double turn on the needle before drawing tight. 2. The oozing which takes place during the passage of the needle is at once checked by the coarse silk and stopped altogether when the loop is drawn tight. 3. The section of the spleen was absolutely bloodless, except in one case where a middle loop had not been tied tightly enough; here bright arterial blood oozed away gently, but a similar ligature at that point, tied tightly, at once stopped the bleeding which did not exceed one drachm. 4. In no case did the ligature cut through the spleen, a little of the pulp only being expressed as the loops were tightened. In the large majority of my cases coarse silk was used for the continuous ligature, but in two or three cases about carballed catgut was employed. 5. The very low mortality.

In cases of rupture of the spleen which are seen in time for surgical interference this continuous ligature may be employed to arrest the hemorrhage, but the procedure to

* The length of this will depend upon the breadth of the spleen, in the present case the circumference of the organ measured a needle was threaded at each end of the silk, but this is unnecessary if the needle is passed into the "upper" surface, as the "double turn" brings the needle back into the right position for further use.

† In some of my cases these were applied before the spleen was ligatured across. The stage at which these vessels are tied is immaterial.

be adopted would depend upon the extent, and position of the rupture. If the injury be of small extent, surrounding the bleeding surface with the continuous ligature may be the best treatment; if of larger extent it would probably save time and be better to excise the damaged portion in the way described. This ligature will also, I believe, be found to be of service in *ruptures* and in small ruptures of the liver. Nineteen dogs had the lower half of the spleen excised without a death; three dogs had the upper half removed with one death. None of the dogs in which the lower half was excised appeared to suffer the slightest inconvenience or shock after the operation, they at once ran about unfettered and ate voraciously anything they were given. The three dogs which had the upper half excised suffered greatly and one died from shock. It is the removal of the upper half of the spleen which is in my opinion so full of danger, so prone to shock and often hemorrhage from some small vessel which has either been overlooked or else has retracted before the ligatures were tied. The removal of the upper half is more difficult than that of the lower half; many more vessels need ligaturing, including, in some cases, the branch from the *phrenic* previously mentioned and which may easily be overlooked with fatal results. This artery was present in two of the three excisions of the upper half and in three of my six total excisions. In man it is also occasionally present. Mr. G. A. WRIGHT, of Manchester, and Surgeon-Major HATCH, of Bombay, report cases where hemorrhage from this vessel caused the death of their patients, and Mr. WRIGHT knows of three other similar cases. Again in removal of the upper half greater tension has to be applied to the pedicle which is, I believe, a distinct cause of shock. Whether the whole spleen or only its upper half be excised does not affect the present argument. In the six cases of total extirpation, before referred to, all the dogs suffered greatly from shock and there were three deaths, the one already mentioned from marasmus and two from shock. If to these six be added the three in which the upper half was excised with one death, we have nine cases and three deaths from shock; a mortality of 33.3 per cent., the survivors also suffering greatly as compared with the nineteen cases of excision of the lower half with no shock or death. May not this great difference be explained by a consideration of the nerve supply of the spleen and of the relative damage done to the sympathetic nervous system in each case? For on these sympathetic nerves depends the *normal* tone of all the abdominal vessels and viscera containing any muscular tissue, and all changes in the *caliber* of these vessels—paralysis or inhibition of their vaso-constrictor fibres causing an extreme fall of blood-pressure, the animal practically bleeding to death into the abdominal vessels—and sudden death has resulted from a slight blow in the epigastric region or from a draught of cold water interfering with the functions of these nerves. It may be well to briefly consider the *blood supply* of the spleen first, as the arteries are surrounded and accompanied by the nerves.

The splenic artery, by its *peritoneal* branches, supplies the body and tail of the pancreas; the *left gastro-epiploic*

† Quoted by Jacobson in his *Operations of Surgery*, second edition, pp. 604, 605.

supplying the greater curvature supplies both the lesser and greater curvatures and sends branches to the greater and lesser curvatures of which some run on to supply the lesser and greater curvatures of the stomach, the vasa brevia, they in turn, as given off towards the termination of the splenic artery, some of these arising directly from the trunk and some from the upper two or three of the terminal or splenic branches. The artery then divides into a little distance from the spleen into a varying number, from five to ten, terminal or splenic branches which enter at the hilus and ramify in the body of the spleen; some of the upper of these, as we have seen, give off short gastric branches. In addition to the above there is often the branch from the phrenic running to and supplying the spleen.

The nerves which accompany these arteries are derived from the solar plexus. Thus, the largest sympathetic plexus in the body, is built up by the semilunar ganglia, nerves from the lumbar portion of the ganglionic cord of the sympathetic, the great splanchnics, and the vagi. Through its secondary plexuses it supplies the diaphragm (in part) and all the viscera and blood-vessels of the abdomen. Of these secondary plexuses the coeliac chiefly concerns the present argument. This plexus is of large size, derived from the fore-part of the solar plexus, is joined by the two small splanchnics, and on the left side is augmented by large, direct branches from the right vagus. It then furnishes the coronary, hepatic, and splenic plexuses; the latter, surrounding the splenic artery, is again joined by direct branches from the left semilunar ganglion and the right vagus. It supplies the pancreas and stomach through its pancreatic and left gastro-epiploic plexuses, some of the latter running on to the spleen, it again supplies the stomach by branches accompanying the arterial vasa brevia and then running with the terminal branches of the artery ends in the spleen. In addition to these nerves there are branches from the diaphragmatic plexus accompanying the branch from the phrenic artery when this is present. During an operation it is impossible, of course, to separate these nerves from the arteries, so that a ligature necessarily includes both. A comparison of the operations may be thus stated. (a) Removal of the whole spleen necessitates the ligaturing of—1. The splenic branches or, what is the same thing in effect, the splenic artery and nerves before they divide into their terminal branches. 2. The vasa brevia arising from the terminal or splenic branches. This must be done even if the trunk of the splenic artery itself be divided or else, with the free anastomoses that exist on the stomach, there will be hemorrhage backwards along these branches; neglect to ligature these arteries is probably the cause of some of the deaths from hemorrhage after the extirpation of the organ. 3. The branches from the left gastro-epiploic and phrenic when present. If these have been divided close to the spleen, as many as from fifteen to twenty small vessels and their accompanying nerves may be included in the different ligatures on the pedicle. If the splenic artery itself be divided, this number would be reduced by the five to ten terminal branches, but the effect on the nervous system would be the same as if the trunk of the artery were involved in one of the ligatures. (b) Removal of the upper half necessitates the ligaturing of the same arteries, except the

lower two or three terminal branches, as many as from twelve to eighteen vessels and nerves being included in the ligatures on the pedicle. (c) Removal of the lower half can be effected by ligaturing the lower two or three terminal branches only. In the two latter operations there is in addition the continuous ligature across the spleen.

From this it will be seen that excision of either the whole or the upper half of the spleen involves great damage to the splenic plexus with its intimate three-fold, if I may so call it—connection with the solar plexus and right vagus; entails direct interference with part of the nerve supply of the stomach and omentum and severe indirect interference with the vagi and all the sympathetic nerve supply of the abdomen; the diaphragmatic plexus is often involved and considerable tension has to be applied to the pedicle, and therefore on the coeliac and solar plexus and the vagi, thus augmenting the interference with these nerves. The excision of the lower half entails but slight damage to the splenic plexus and therefore but slight indirect interference with the solar plexus and vagi; the nerve supply to the stomach, the omentum, and the diaphragmatic plexus is never involved and but slight tension has to be applied to the pedicle. As shock is due to severe inhibition and exhaustion of nerve function¹ and the greater the lesion the greater is the shock that results, this great difference in the amount of interference with the nervous system in these operations is the explanation, I believe, of the great difference in the amount of shock following them; and in the excision of the whole spleen or of the upper half the resultant shock is due to inhibition and exhaustion of the vaso-constrictor fibres of the abdominal sympathetic, and is probably intensified by great interference with the proper performance of the functions of the heart, lungs, stomach, &c., reflexly by means of the vagi. These considerations would induce me to advise in suitable cases in the human being—e.g., abscess, tumour, or cystic disease confined to the lower half or in hypertrophy which resists medical treatment—the excision of the lower half in preference to that of the whole spleen, as the same object would be attained—the removal of the disease or the enlargement—whilst a considerable portion of the spleen would be left to carry on its function, and further, there would be, as a reasonable inference, a considerable reduction in the death-rate.

Immediately after the operation there was as a rule a slight loss of weight, this was quickly recovered, and all the dogs, except one gained weight subsequently, the least gain being 4 lb. and the greatest 8 lb. This increase in weight was in the majority of the cases undoubtedly due to regular and liberal feeding which by itself previous homeless lives the dogs had been accustomed to, but in four cases in which the gain in weight was greatest the dogs were small and probably not fully grown at the time of operation, so that part of the increase was most likely due to the normal growth of the dogs. The temperature (rectal) of these dogs was much constant; in nine of the twenty-one survivors it never varied from 100°F.; in three it never gets reached 100°F., ranging from 102°F. to 102.8°F. in eight the highest was 100°F. and the lowest

¹ Foster's Text-book of Physiology, 2nd edition, Part III, p. 308.

102°; in the other on one occasion it reached 100°. The greatest individual range of temperature, except one was 0.6. All these cases were operated upon with a daily atmospheric temperature of from 99° to 104° in the shade. The case alluded to stands by itself; it had been accustomed to regular feeding prior to operation, having been a house-dog; it was the only one in which the temperature exceeded 106°, in which there was loss of weight and a marked or permanent alteration in the number of red corpuscles and the only one in which malarial parasites were found in the blood, which probably is the explanation of all these differences. Two of the dogs were subsequently killed by an overdose of chloroform; the spleen had assumed a flattened globular shape and had increased slightly in size since the excision of the other part, but had not attained its original size. The capsule at the site of section showed signs of old inflammation and the omentum was adherent at this point. In one case the continuous ligature was found encapsuled, in the other it had been absorbed.

The blood—The examinations of the blood and the enumeration of the corpuscles were most interesting. In an extensive tabulated statement which records the details of a series of experiments but which the limits of our space preclude our reproducing, the first five cases are excluded from the following remarks as the number of corpuscles could not be ascertained before operation, and the subsequent enumerations in Cases 1 and 2 showed only a steady increase in number of the red and white coincidently with the growth of the pups; Case 3 showed no marked change and Case 5 will be referred to later. Before operation the number of red corpuscles varied from 3,500,000 in Case 12 to 6,000,000 in Case 16, the average being 4,920,000 per c.mm. If Cases 11, 12, and 21 be excluded, for reasons to be shortly stated, the average would be 5,170,000 per c.mm. The white varied from 50,000 in several cases to 60,000 in Case 6, the average being 41,000 per c.mm.; the proportion of white to red being 1 to 120. After operation in the majority of cases there was no marked change in the number of red corpuscles; excluding Case 10 they averaged 4,900,000 per c.mm., as against 4,920,000 before operation; excluding Case 11, 12, and 21 the average would be 5,100,000 per c.mm., as against 5,170,000 before operation. This small difference might well be due to errors of observation before or after operation, any one of which would necessarily be multiplied 10,000 times. The white corpuscles showed an immediate increase in number after operation, the smallest increase being 20,000, the greatest 40,000, and the average 30,000 per c.mm. the ratio of white to red being altered to from 1 to 70. This increase reached its maximum soon after the operation, began to diminish a fortnight to six weeks after, and in those cases that were under observation two months after operation the number of white and the proportion of white to red was normal again. This temporary increase was probably due to the irritation of the continuous ligature and the localized inflammation of the spleen and its capsule at the site of section. The Cases 11, 12, and 21 were small dogs which increased considerably in weight after operation; the red

cells also increased in number, and from a comparison of these cases with the pups (Cases 1 and 2) it is probable that they were not mature at the time the operation was performed, and that the increase in weight and in the number of the red cells was consequent to the growth of the dogs.

In the ordinary microscopic examination, stained and unstained—and the following remarks apply to all twenty-one surviving cases—the red cells were normal, in a few cases they were vacuolated, and in Case 10 pale and deficient in hæmoglobin. The white were apparently of two kinds, small and large. The small variety was circular, usually finely granular, with two or more nuclei, but often contained only one nucleus and at times were coarsely granular; they were never seen to change shape. The large variety was usually coarsely granular with one nucleus, the latter being of various shapes, semilunar, round, serpentine, &c., often giving to the cell the appearance of being multi-nucleated; occasionally these large cells were multinucleated and rarely finely granular; they exhibited free amoeboid movement. Sometimes the large and at other times the small variety was more numerous. Although these two kinds were the usual white cells seen at times, other forms were found, intermediate in size, sometimes mononucleated, at others multinucleated, sometimes coarsely, at others finely granular and rarely having both fine and coarse granules in the same cell. The impression was thus given that the large and small varieties were only stages in the life of the same cell. In Case 5 there were seen occasionally very large multinucleated white cells with a diameter two or three times that of the ordinary large variety mentioned above; they exhibited free amoeboid movement, had coarse and fine granules in the same cell and often large vacuoles. One of the most interesting points in the blood examinations was the appearance, in Cases 5, 6, 8, and 9, of bodies which were extremely like those LAYBURN discovered in malarial blood. So great indeed was the similitude that had these bodies been seen in the blood of a patient suffering from malarial fever, I have no hesitation in stating that they would have been pointed out as fairly typical specimens of the "rosette" and spherical extra-corpuscular, or free stages, of the parasites. I hope in another paper to describe these bodies more fully. An interesting blood worm was seen in Case 10 and watched for three-quarters of an hour. It was round in shape and in breadth nearly but not quite the diameter of a red cell. It was impossible to define its length on account of the free movements when alive and to its being coiled up when dead, but when nearly straight it reached across the field (Leitz eye-piece 3, objective 7), one or other end being out of sight. Its body was cylindrical, tapering rapidly near the tail. Its head was slightly smaller in diameter than the body and blunt-ended with a transverse "depression" rather nearer the under than the upper surface. When first seen, the worm was gently waving its body in exactly the same way as an eel does when swimming; at short intervals it was seen to retract its head and then rapidly shoot it out. By careful watching it was seen that a red corpuscle was the object aimed at, and that as the head shot forward, a triangular-shaped "tongue" was protruded from the depression; this was at once withdrawn when the corpuscle was

which was the first or only blow, a white cell was seen to leave the "mouth" of the worm, and the deposition of the "mouth" of the worm on the red cell was paler than before. After a few blows the white cell was attacked and about two or three blows the worm moved on and to the field had to be changed and as the white cell was lost, when first attacked, this cell was moving and my impression was that its movement ceased with the attack, but too short a time was allowed to be sure of this. In about half an hour the worm gradually ceased to attack the red cells and its movements became much more vigorous, swimming about so rapidly that it was difficult to change the field quickly enough to keep the worm in sight. Occasionally at this stage it coiled itself up like a watch-spring and suddenly straightened itself out, dashing the red cells about in all directions; these convulsive or lashing movements became more and more frequent until there was hardly any intermission. The worm then appeared to grow weaker, its movements became less in number and vigour, and at last it lay still, coiled up in two and a half convolutions. As this change of movement was taking place the blood was seen to be coagulating, this probably causing the death of the worm, which then appeared to be faintly striated both longitudinally and circularly.

In conclusion, I desire to express my grateful acknowledgements to the medical department of H. H. the Nizam's Government and to Surgeon-Lieutenant-Colonel LAWRENCE, the Residency Surgeon and Principal of the medical school, for the kindness and courtesy they extended to me during my residence in Hyderabad, and for the facilities and resources they so willingly placed at my disposal for these and other investigations. My thanks are also due to Dr. NELLY EVANS, Dr. KALAYAN RAO, and Dr. SYED MOHAMMED for their assistance in the blood examinations. Dr. EVANS also performed successfully several partial excisions of the spleen by the operation described.

—10—

DISEASES OF THE CORNEA.

By G. C. CALDER, M.B., M.S.

Professor of Physiology, Lahore Medical College,
and Surgeon to the Eye and Ear Out-patient
Department, Mayo Hospital, Lahore.

Types of Corneal Ulcers.

(a). *Absorption ulcers* (indolent ulcers).—These ulcers are characterized by their essentially chronic course, by their being unattended with symptoms of inflammatory irritation, and by their showing little or no tendency to extend to the deeper layers of the cornea or to terminate by cicatrization. They appear suddenly, that is, are observed without preliminary symptoms, at the loss of substance was the result of absorption of the corneal tissue, and do not seem to go through any stage of evolution or repair. Besides occurring in chronic and tuberculous subjects, they are very common in cases of chronic trachoma. They are associated with transparent striae and patches, rounded and radiating borders free from any but a very

secondary inflammatory zone. The two most important forms of indolent ulcers are—

1. The shallow (non-infiltrative) central ulcer of chronic and trachoma (see above).
2. The excavated or gorged ulcer, which occurs chiefly in children, and remains stationary for months, rebellious to every form of treatment. The ulcer is generally marginal, and on account of its permanent character and absence of pain, photophobia, and secretion, it is very liable to be overlooked. Complete healing of the ulcer rarely, if ever, occurs, in spite of the apparent attempt at repair, which is observed in the form of a feeble vasodilatation. A clear facet always remains upon the cornea giving rise to disturbance of vision from irregular astigmatism.

(b). *Serpiginous or creeping ulcers*.—These are characterized by a slow creeping progress in the cornea. They are met with under several forms.

1. *Ulcus serpens of Sæmisch*. Syn. *Ulcus septicum* (Stellwag); *Hypopion keratitis* (Beer). Begins generally near the center of the cornea in the form of a grayish infiltration superficially situated, which in an exceedingly short time by the breaking down of the anterior lamellæ, becomes converted into an ulcer with sharply-defined margins. On one part of the margin there is an elevated arc-shaped infiltration yellowish than the rest of the ulcer; it is along this curvilinear elevation—known as the arc of propagation—that the ulcerative process extends rapidly both in superficial area and in depth. Hypopion and striae are, as a rule, present from the beginning. Inflammatory symptoms may or may not accompany the local lesion.

Sæmisch ulcer is most frequently caused by slight trauma of the cornea, infected either by ordinary pyogenic microbes, or what is more probable, considering the malignancy of the ulcer, by a specific micro-organism not yet isolated.

It chiefly attacks people above middle age, notably the old and feeble. Rarely it is found occurring in young people. In its origin, in the course which it runs and in its very serious terminations, the *ulcus serpens* of SÆMISCH forcibly calls to mind, what we have before described as corneal abscess. Indeed many authors, among others VON AHL and ED. WEBER, consider the *ulcus serpens* to be identical with abscess, the former even going so far as to say that SÆMISCH, in his contention that his "*ulcus serpens* has nothing to do with corneal abscess" has created a new nomenclature without cogent reasons. If, however, the essential difference between an ulcer and an abscess consist in the anatomical fact, that in an ulcer the suppuration is superficial ab initio, then we must regard the lesion as an ulcer and not as an abscess. The difference is in reality a technical one, for it must be confessed that the clinical history of the *ulcus serpens* does not justify the creation of a broad line of distinction between it and abscess.

2. *Ulcus rolans of Mooren*.—Is a marginal creeping ulcer of the cornea, and is always accompanied by marked inflammatory symptoms. The crescent-shaped zone of ulceration is separated from the healthy portion of the cornea by a grey clouded and undermined margin. The evolution of the ulcer is characterized by alternate

exacerbations and remissions. After the lesion has lasted sometimes it begins to show signs of healing; the ulcer cleans and becomes partially vascular. These favorable indications are however transient in duration, and very deceptive. A relapse quickly follows, symptoms of irritation set in, and the ulcer regresses forwards in the cornea. This kind of discontinuous invasion is repeated many times until the whole of the cornea is involved in the process of destruction and blindness supervenes. Perforation of the cornea, which may be considered the rule in SAMMON'S ulcer, again occurs in this disease. Ulcus rodens is essentially an affection of old age.

3. "Snail-track" ulcer of *keratitis fascicularis*, results from a phlyctenular ulcer. As this heals a leash of blood vessels run up to it from the limbus and helps in the process of cicatrization. Whilst the ulcer is healing by its margin—that is at the part turned towards the limbus—its opposite part directed towards the center of the cornea, continues to creep forwards, carrying with it the track of blood vessels (*vascular fasciculus*, or *herpetic bridge*). When the ulcer heals, the vascular fasciculus disappears, but always leaves behind it the evidence of its existence in the form of a permanent stripe of opacity. The snail-track ulcer throughout its evolution remains superficial and never gives rise to perforation. It is a disease of childhood and adolescence, and occurs in scrofulous subjects.

4.—*Dendritiform ulcers*. These ulcers occur in that form of keratitis described as *keratitis dendritica* or *keratitis mycetica*. I have never observed a case of this disease in my out-patient clinique. It is more than probable that the form of keratitis is dependant upon a special microbe. The inflammation extends in a characteristic ramifying manner (arborescent or dendritic) quite superficially, each branch having at its end a small rounded elevation. The ulcer so produced is furrowed—each furrow or axis of ulceration is bordered by slightly elevated ridges of infiltration.

Dendritiform keratitis occurs in the acute form as well as a sub-acute or torpid lesion. In the former case the symptoms of inflammatory irritation are marked from the beginning, and there is a tendency for the ulcerative process to implant itself in the deeper layers of the cornea; in the latter case, on the contrary, there is little or no inflammatory irritation, and the ulceration is restricted to the anterior epithelium. The disease appears never to be complicated with iritis; BERRY has, however, seen it occasionally associated with hypopyon. According to FUCHS, *keratitis dendritica* is simply a form of *herpes cornea febrilis*. The ulcer formed by the rupture of the herpetic eruption extends in a linear manner through the cornea, at the same time becoming forked and giving out lateral branches—hence the formation of the characteristic branch-like figure.

The treatment of dendritic ulcers consists in washing the eye with weak corrosive sublimate lotion, and repeated instillations of eserine.

Treatment.—Corneal ulcers occur under such protean forms and are produced by such a variety of causes that it is impossible to formulate rules of treatment which shall be universally applicable. The following remarks, how-

ever, may be taken as indicating the general principles upon which the treatment of ulcers of the cornea is to be based:—

1. In all cases it is imperative to give careful attention to the *indicatio causalis*. A large proportion of primary ulcers of the cornea are of traumatic origin, the wound becoming infected either by the body causing the injury itself, or by a source of infection already present in the eye, a purulent blenorrhoea or a dacrycystitis, for instance. The removal of these, therefore, constitutes the first step in the treatment of the induced condition. Among foreign bodies in this connection are to be included inverted cilia, calcareous concretions on the inner surface of the upper lid and marginal papillomata. In ulcers which arise secondarily to inflammatory conditions of the conjunctiva, such as catarrh, acute blenorrhoea, or trachoma, the treatment of the primary lesion is of the utmost importance, and in the majority of cases it will be found that the healing of the local suppuration keeps pace with the progress towards recovery made by the particular lesion of the conjunctiva upon which it is dependant. The point of importance to be borne in mind is that cauterisation of the conjunctiva is not contra-indicated because of the presence of corneal ulceration. In trachoma, for instance, to which undoubtedly are due the major part of corneal secondary ulcers which come under our notice in out-patient ophthalmic practice, it would be folly to expect any amelioration of the ulcerative process, if the surgeon abandons the cauterisation of the conjunctiva with the sulphate of copper crystal or the solution of nitrate of silver. It is a canon of ocular therapeutics that "infiltration is a formal indication against any irritating agent," and therefore, what is wanted in the treatment of a corneal ulcer caused by trachoma so long as any infiltration lasts, is not the abandonment of the appropriate treatment of the original disease by caustic, but the prevention, as far as possible, of the cauterising agent coming in contact with the cornea. If sulphate of copper is selected for the treatment of the trachomatous condition, its application should immediately be followed by a copious abluion of the everted lids with clear cold water. If, on the other hand, silver solution is chosen as the cauterising agent, it should be applied according to the method of A. VON GRAEF, by means of a camel's hair pencil, or a tampon of cotton wool carried at the end of a probe, directly to the palpebral conjunctiva, and any excess that may be present, should be washed off with water containing a small quantity of sodium chloride. It is a fatal error, (and one which it is to be regretted, is often committed), to use in cases of conjunctival inflammations complicated with ulcer, the silver solution as a collyrium—the so-called "caustic lotion drops."

It is not necessary to add that cauterisation of the conjunctiva with acetate of lead when ulcers are present upon the cornea is a wholly unjustifiable proceeding.

2. The *indicatio morbi* requires that the treatment should procure rest for the eye, reduce the inflammation, retard the progress of the ulcer and hasten the process of repair.

The best method of obtaining rest for the eye is to keep it bandaged. The object of bandaging (a pre-

negative bandage is sufficient in all recent cases) is two-fold; first to secure immobilisation of the lids, which by their movement in every act of opening and closing produce friction of the ulcer and thus keep up the irritation; and, secondly, to prevent dust falling upon the bottom of the ulcer and acting as a mechanical irritant. In those cases in which the corneal ulcer is associated with profuse discharge, as in purulent conjunctivitis, the bandage should either not be applied at all, or if it is used, it should be frequently changed and the eye washed out with an antiseptic lotion.

The use of the bandage should not be discontinued until the regeneration of the epithelium is completed. During the acute stage, the treatment should consist in instilling into the eye a solution of eserine and cocaine, 2 to 4 grains of each alkaloid to the ounce of distilled water, three or four times a day, or oftener. In this way pain and photophobia are both combated successfully, and the progressive period considerably reduced. Should, however, the pain be very acute and the local measures just mentioned found to be insufficient, recourse may be had to hot poppy or belladonna fomentations, or to hypodermic injections of morphia. In atrophic cases a leech applied to the temple is beneficial.

When the ulcer has become clear, or when from the beginning it has been of the indolent or torpid type, we should resort to local stimulation by means of irritants. Those in most frequent use are powdered calomel, the ointment of the yellow oxide of mercury, 1 to 4 per cent strength; the tinctura adstringens luteum* of the Austrian Pharmacopoeia (also called Hoser's eye-water), and SYDENHAM'S tincture of opium, according to the following formula:—

Tinct. Opii. (SYDENHAM)

Aq. dest. aa ʒss.

Whilst these remedial measures are being employed to stimulate the process of reparation, the treatment of the primary lesion should not be lost sight of—if a relapse to the acute stage is to be averted. Particular attention is to be paid to the conjunctival secretion, for it is an amply attested fact of experience that the transparency of a corneal cicatrix depends in a large measure upon the amount of secretion during the period of healing of an ulcer; the less the secretion the more transparent is the reparation tissue and *vice versa*.

Constitutional treatment, in the shape of cod-liver oil, iron, quinine, a liberal and sustaining diet, in all those cases in which there is reason to believe that the patient's general health has given way, is to be carried out in accordance with general principles. The importance of constitutional treatment as an essential factor in restoring the cornea to a normal condition is brought forcibly into prominence in cases of ulcers due to strumous or lymphatic conjunctivitis. These ulcers occur almost exclusively in weakly, poor, and ill-fed children or in adults who are more or less in a state of physical exhaustion. In such cases, whilst the local treatment proves undoubtedly beneficial, the duration of the illness, and what is of still greater importance, the

tendency to recurrence which these ulcers manifest, are greatly minimised when attention is simultaneously paid to the general condition of the patient. In out-patient ophthalmic practice, the greatest drawback to success, in a large proportion of cases, arises from the inability of the children's parents to carry out the surgeon's advice as to the necessity of better hygienic surroundings, and of a more generous regime as to diet and clothing.

Spreading ulcers.—It is a fortunate circumstance that a very large proportion of these even in their worst form—as for instance Saemisch's ulcer—are amenable to medicinal treatment without surgical interference.

The drug, par excellence, which we rely upon for the purpose of curing extensive infective ulcers of the cornea, no matter how originating, is eserine, in combination with the hydrochlorate of cocaine. The formula for the collyrium being:—

Eserine Sulph.

Cocain Hydrochlor aa gr. ii.

Aq. dist. ʒi

Under the influence of these drops instilled into the eye three to six times a day, large sloughing ulcers of the cornea with or without hypopyon, heal as if by magic, and the resulting opacity is thinner and more circumscribed than under any other form of treatment. The power of eserine to reduce intra-ocular tension is well known. "This pressure," as Dr. EDWARD MEYER has remarked, "is one of the chief causes in keeping back the normal nutrition and the reparative process in the cornea;" hence the beneficial action of eserine in suppurative lesions of the cornea.

Apart, however, from this indirect influence, there can be no doubt that eserine acts in a very direct manner upon the suppurative process itself by checking diapedesis on the one hand, and by promoting the absorption of purulent matter on the other, by causing dilatation of the ciliary vessels.

The objection to the use of eserine is generally urged in those cases of corneal ulcers, in which a symptomatic iritis complicates the issue. No doubt eserine produces congestion of the ciliary body and iris, and if used alone, would enhance the already existing iritis and lead to troublesome synechia. Its combination with cocaine, however, entirely does away with such a possibility—and indeed there is, from this point of view, no reason against the intercurrent use of atropine when there is iritis present, say once a day until the iritic inflammation has subsided.

I have obtained the most beautiful results with eserine and cocain in numberless cases of deep progressive ulcers of the cornea, and the irresistible conclusion drawn from a very large experience of the action of these drugs used in combination, is that for all forms of progressive ulcers they are to be regarded as specific remedial agents, just as much as preparations of mercury and iodide of potassium are for syphilis. Of the value of atropine in cases similar to those in which I use eserine and cocain there can be no doubt, and occasions do arise in which it is much better borne. In general, however, it is the inferior agent of the two, and except for special indications, preference should be given to eserine.

* Form: For HOSER'S eye-water:—

Am. Chlorid 40 s. gr.; Zinc sulph. 150 s. gr. Dissolve in 200 grms. of Aq. dist. and add ʒi of 40 s. gr. of Camphor in 20 grms. of dilute alcohol and 10 s. gr. of Safran. Digest for 24 hours with frequent agitation and filter.

Iodine is also, in many cases, an effective remedy. It should be applied by means of a small piece of cotton wool rolled over the end of Bowman's probe, to the sides and bottom of the ulcer, care being taken that the fluid does not come into contact with the healthy portions of the cornea. After the application, which causes no pain, strapping should be fastened and the eye bandaged up. One or two applications a day are enough; it is most gratifying to find even large hypopions quickly disappearing under this treatment and the ulcer entering upon the stage of regression and healing. Iodine possesses marked antiseptic properties, and is free from the liability to precipitate insoluble saline compounds leaving indelible opacities, and beyond causing slight abrasion of the epithelium, which however is quickly regenerated, it gives rise to no irritation of the cornea. I have not known it to cause anyiliary blepharitis or to form deposits in the inferior cul-de-sac of the conjunctiva.

Pure carbolic acid and iodoform, very finely powdered, are remedial agents which have been favorably spoken of, but of which I have little or no experience.

Whilst the treatment with one or the other of the remedies spoken of is going on, the process of repair is to be encouraged by the frequent use of *hot compresses*, and the washing out of the conjunctival cul-de-sac with antiseptic lotion such as corrosive sublimate lotion (1 to 10,000).

The compresses are made with thin muslin folded several times and cut into 2½-inch squares, or with antiseptic gauze cut to the same size. These are wrung out in hot carbolic water (120° F), or sublimate lotion, and applied every day for an hour or more. They should be changed as often as may be necessary in order to be constantly warm.

Recently Dr. GEORGE WHEATLEY of the Addenbrooke's Hospital, Cambridge, has brought to the notice of the profession the value of airof powder in the treatment of septic ulcers of the cornea associated with hypopyon. According to him, some of the most threatening cases have been treated successfully with this powder. I give the method of using airof in WHEATLEY's own words—

"The eyelids are held open and the airof powder flicked on to the eye with a dredger, the powder turns gradually to an orange color, and in three to six hours the conjunctival sacs are washed out gently with boric water, which brings out superfluous cakes of yellow powder. The airof is again used as before, and this proceeds every few hours, the eye being treated by the open method—no bandage or pad is used—but the patient is kept in bed.

"The ulcer heals, and the pus is absorbed in a proportion of cases greater, as far as I can judge, than by other methods. The eye is singularly tolerant of the airof; in no case have I seen signs of irritation from its use, and when incision and cautery have been used, the after-treatment by airof has seemed to be satisfactory."—*British Medical Journal*.

In the majority of cases, even the worst forms of corneal ulcers yield to medicinal treatment, conducted in a rational and conscientious manner, but if in spite of all efforts the ulcer continues to spread, and in case of its spreading downwards perforation is impending, we must resort to surgical intervention. The means at our disposal are: paracentesis of the anterior chamber, cauterisation with the actual cautery (galvano-cautery, thermo-cautery, or Paquin's); or in the absence of these a heating needle or a wire made red-hot in the flame of a spirit lamp; curetting with a sharp spoon; and SAMPSON'S

ON A METHOD OF OPERATING IN CATARACT.

By JESSE, SARGENT MONTAGUE, GORTA, L.M.S.

Late House Surgeon, Eye Infirmary, Medical College Hospital, Off. Civil Medical Officer, Malabar.

THE remarkable success which attends Dr. SAMPSON'S operations for cataract at the Eye Infirmary, Medical College Hospital, prompts me to publish the method of operation with its after-treatment, as practised by him in that hospital.

The subject may be conveniently described under the following heads:—

I. *Selection of patients*.—As to the general health of the patient, it is desirable, as in every other surgical operation, that it should be as good as possible.

Diabetes is no contra-indication; heart disease, anaemia and age do not form any obstacles, persons over eighty years have been successfully operated on. Patients suffering from chronic Bright's disease, with a large quantity of albumen in the urine are to be rejected, as in these cases there is a great danger of sloughing of the cornea; and, further, the operation might be rendered unsuccessful, by the case being complicated with previous retinal changes.

As to the condition of the eye itself, it should be ascertained that the cataract is quite mature by the aid of the ophthalmoscope. The eye should be carefully examined for intra ocular diseases. It is the usual practice here to examine the fundus of every patient suffering from incipient cataract, and to note down the result in his ticket for future reference. When the lens of the eye to be operated on is too opaque for ophthalmoscopic examination, we might sometimes get some useful information by examining the fundus of the other eye. But unfortunately we often get cases with advanced mature cataract in each eye. In such cases our chief reliance is on the patient's perception of light. This should be examined with utmost care. In an uncomplicated case of cataract of the most opaque kind perception of light is always left behind.

The drooping head, the wrinkled forehead, and the cautious walking of a cataract case, may be well contrasted with the erect head, the vacant staring look, and the peculiar walk, of a case complicated with serious changes in the fundus.

The condition of the appendages of the eye should be examined. Granular ophthalmia, conjunctivitis and diseases of the lachrymal passages should be cured or relieved as much as possible before the operation is undertaken. Successful operation may, however, be performed in the presence of slight granular ophthalmia.

Of other minor complaints, such, if troublesome, will have to be relieved before the operation.

II. *Preparation of the patient*.—Soon after admission into the hospital, the patient to give a good bath (preferably a hot one), and his clothes are changed. Whenever possible, the patient is allowed to rest for three or four days or more before the operation. This is all the more important in the case of half-cured patients. During this period boric acid lotion (gr. viii to i oz.) is dropped into both eyes three times a day. On the day previous to the operation, a mild purgative is

and astringent action (gr. ii to i oz.) is dropped into the eye three daily. On the previous evening and in the morning of the operation, the eye and its neighbouring parts, especially the inner and outer canthi of each eye, are thoroughly washed with tepid borie lotion. Solutions of mercury lotion is never used, as it always causes some irritation in the eye and tends to produce some haziness of the cornea. A few minutes before the operation, while the instruments are being prepared, a few drops of cocaine solution (gr. xvi to i oz. freshly prepared with boiled distilled water) are dropped into the eye at intervals of a few minutes; care being taken not to drop too much of cocaine, as when put in excess it has a tendency to lower the vitality of the cornea, which is so important for subsequent healing.

III.—*Instruments, dressings and lotions to be kept ready are*:—A lid spring top speculum (Weise), one fixation forceps (with double teeth by Francis without a spring catch), von Graefe's cataract knife—as sharp as possible, curette, cystitome (Graefe's) and a hard rubber spoon; and in case there be occasion to use, a bent iris forceps, iris scissors and a scoop or vicia. Preferably these instruments should be by Weise.

During the whole period of operation, a small quantity of borie lotion is kept boiling in a small toy *degch* on a retort stand heated with the flame of a spirit lamp. The instruments are kept in a clean, dry porcelain dish, and each of them is dipped into the boiling lotion just before use. The instruments are boiled every time they are used. (Before the instruments are finally put back in the box, each of them is boiled, carefully dried, and dipped into absolute alcohol.)

Small bits of sponge or absorbent cotton-wool are kept wet with tepid borie lotion in a clean porcelain cup. These are used to wipe away discharges, cortical masses, &c., from the conjunctiva and are not used a second time. The assistant hands over each instrument in its turn in such a manner as to make it unnecessary for the operator to look away from the field of operation.

As to dressings: two pads of sal alembroth wool (one for each eye), a little sanitas vaseline and soft muslin roller are all that is required. The following eye lotions should be kept in readiness—

1. Sol. atropine sulph. (gr. iv to 1 oz.)
2. Sol. eserine sulph. (gr. ii to 1 oz.)

IV. *The position of the patient*.—The patient lies down on a table or couch of convenient height, with his head resting on a pillow high enough to make the plane of his face horizontal. In hospital practice where several patients are to be operated at the same time, it is a good plan to spread a canvas stretcher over the table, so that when the operation is over, the patient can be easily carried to his bed without the least exertion on his part. The table should be so arranged that good light falls on the patient's face, and no shadow is cast on it by the operator's hand. Direct sunlight and draughts are to be carefully avoided. In case of deficiency of light, an assistant can reflect light with an ordinary hand mirror.

The operation.—The operation usually performed here goes by the name of Von Graefe's modified method. Ir-
idectomy is not performed as a routine practice. In cases complicated with posterior synechia, or where there is

any excess of intracapsular lens, or where the lens is unusually big, iridectomy is performed.

Just before the operation, the operator and his assistant wash their hands with antiseptic soap and water. While the instruments are being made ready, the cocaine drops are put in. Generally three instillations of a few drops each are quite sufficient to produce the necessary anaesthesia. Sometimes for nervous patients it is better to put a few drops of cocaine lotion in the other eye also. The head of the patient should be covered with a clean towel. The patient is directed to look downwards with his mouth slightly open; he is not to strain or make himself stiff in any way.

The operator stands behind the patient, and the speculum is applied. He holds the knife in the right hand for the right eye, and in the left for the left eye, and with the other hand he holds the fixation forceps. The globe is seized and drawn slightly downwards by the conjunctiva and sub-conjunctival tissues close to the cornea on its outside, a little below the termination of its vertical axis. The forceps should be held at right angles to the surface of the globe, drawing the conjunctiva away from its surface, and it should exert no pressure over the eye-ball.

The section is made on the upper edge of the clear cornea so as to include about two-fifths of its circumference. "The precise length of the incision, as determined by the points at puncture and counter-puncture should be modified in accordance with the surgeon's estimate of the diameter of the hard nucleus."

The point of the knife is entered in the margin of the clear cornea just in front of the sclero-corneal margin and is first directed towards the centre of the eye-ball; and as soon as the anterior chamber is reached, the handle of the knife is depressed and the blade is carried across in front of the iris, so as to transfix the cornea at the same level as its point at entrance. By a few gentle sawing movements of the knife the incision is completed, keeping the edge of the knife well upon the border of the cornea. Just before the completion of the section, the knife is cutting its way out, its edge is sloped a little forwards—so that the middle of the incision is on a slightly anterior plane to that of either end. By this procedure a nice little lid is formed, which helps so much in the ready union of the wound.

It will be observed that the incision is confined strictly within the corneal tissue. In case of cataracts with milky cortex, the section should be smaller as the nucleus is always a small one.

2nd stage: Capsulotomy.—Now the surgeon puts away his knife and introduces the cystitome flatwise. With the blunt angle of its end first, keeping it well up, close to the posterior surface of the cornea. Then the instrument is turned, so that its point is directed towards the lens, and the capsule is torn freely by a few gentle rounded movements. During this process, the cystitome should be held in a slightly oblique manner, and it should not dig into the lens, as then it is apt to dislocate it. The cystitome is withdrawn sideways with its blunt end directed towards the wound. No sooner the capsule is torn, the lens advances forwards, distending the enlarged pupil before it.

3rd stage: Delivery of Cataract.—Now the patient is directed to look downwards towards his feet, avoiding all

efforts at straining. The eye is steadied as before by the fixation forceps, care being taken that it does not exert any pressure over the globe. The convex surface of a shell spoon is now laid against the lower part of the cornea, corresponding with the lower margin of the lens, and firm and at the same time gentle pressure is applied, at first in a backward direction, so as to cause the lens to rotate on its horizontal axis and to present its upper margin at the wound; then the pressure is changed into a backward and upward direction, so as to coax the cataract out. As soon as the diameter of the lens has passed through, the pressure is relaxed, and as the cataract slips through the wound, the spoon is made to follow it. With a bit of wet sponge or with the back of the shell spoon, any cortical fragments at the margin of the incision are swept off. Now, at this stage, sometimes a bit of iris is found to be protruding through the wound. This should be at once reposed by gently separating the lips of the wound with the edge of the spoon or with a spatula. The proper management of pressure is indeed a very important portion of the operation, and can only be learnt by experience. In inexperienced hands the escape of the vitreous with consequent loss of the eye is mainly due to improperly applied pressure. Dr. CARTER truly remarks that "the proper management of pressure is the last attainment of the operator for cataract."

4th stage or toilette of the wound.—After the delivery of the cataract, the cortical masses are removed in the same manner as the lens by gentle pressure with the curette or with a bit of wet sponge. To press the cortical matter out, the pressure should be directed backwards and slightly upwards. Any cortical masses sticking inside the anterior chamber or at the upper part close to the section are removed by introducing the curette and drawing them out. In this stage, if the capsule is seen to be opaque, it is gently pulled out with a pair of bent iris forceps. Thus the pupil is freed of everything till it becomes quite black, and the vision becomes such that he is able to count fingers at several feet.

Now, if the patient begins to move his eye about, or to strain (as he often does at this stage), it is wiser to take off the speculum and to leave the eye-lids to the charge of the assistant, as the speculum always exerts certain amount of pressure on the eye-ball, and more so when the eye is moved in different directions, and this pressure is quite enough to rupture the hyaloid membrane and cause an escape of the vitreous.

As to the introduction of the scoop and other instruments into the anterior chamber, it might be said that the fewer number of times the instruments are introduced inside the eye, the better. The less the eye is handled, the quicker the wound heals, and the lesser the chance of complications. In experienced hands, one introduction of the curette is quite enough to clear the pupil. Sometimes a second introduction becomes necessary. After this, the wound itself will have to be seen too. If the pupil is noticed to be irregular or not quite round, it will be found that a fold of the iris is caught between the lips of the wound. This is easily remedied by separating the lips of the wound with a curette or spatula, and the iris at once falls back to its original position by its own

elasticity. Then the wound should be freed from any tag of capsule adhering to it.

Now the conjunctival sac is thoroughly cleaned of cortical masses, &c., and both eyes are closed. If there be much contraction of the pupil or if there be any suspicion of a bit of cortex having been left behind, a drop of atropine lotion is put in, over the closed lids a circular piece of soft muslin (big enough to cover both the lids) smeared with sanitas vaseline or pure vaseline is placed and moulded to them in such a manner as to be without a wrinkle. Over it a small ball of sal alembroth wool, big enough to cover the lids, is placed; over the other eye also a pad of sal alembroth wool is put and a figure of 8 bandage is applied, and the patient is put to bed. The vaseline prevents the dressing from becoming hard or from sticking to the skin of the lids, and makes it easy to take off the first dressing.

The patient is not allowed to move about, or sit up in the bed or strain or to talk much for the first 24 hours. He is kept on slops for the first 48 hours, after which he is allowed soft food, and to sit up a little on the bed. If the patient happens to be very feeble and debilitated, he is allowed a couple of ounces of brandy for the first three or four days.

Dressing.—After 24 hours the first dressings are changed. If everything goes on well, the examination of the eye is put off till the fifth morning. Swelling of the lids, chemosis, watery, or muco-purulent discharge or pain in the eyeball are signs which call for an early examination and appropriate treatment. At the first and subsequent dressings, the lids are freely douched with tepid boracic lotion and a drop of atropine lotion is instilled. Subsequent dressings are applied every 24 hours. Both eyes are kept closed with light pads of sal alembroth wool till the fifth morning, when, if the case has been progressing normally, the wound is found to have united, the pupil dilated and black, with only a slight ring of redness round the cornea. From the fifth day, only the eye operated on is kept closed with a light pad and bandage. This is continued as long as there is much congestion. Afterwards a green shade is put on.

Before concluding, I desire to express my indebtedness to Brigade-Surgeon-Lieutenant Colonel R. C. SAUNDERS, for kindly permitting me to publish this paper, and also for going over the manuscript.

"CATCHING COLD" AS A CAUSE OF DISEASE.

FROM a general survey of the subject, CHALMERSKI concludes that "catching cold," in the ordinary sense, is not a causative factor in disease, playing in general a very subordinate part as an etiological agency. In inflammatory diseases it may act only as a predisposing factor. "Catching cold" depends upon the activity of thermic agents which are usually not to be avoided; that is, upon the influence of slight degrees of cold. The degree of cutaneous reaction to the given thermic stimulus is an indication whether the individual may take cold under certain conditions. The degree of disposition to "catching cold" forms no constant peculiarity of the given individual. Individuals of advanced age, febrile patients, and those suffering from renal disease appear to be more disposed than others to disease resulting from "catching cold." Between the predisposition to such disease upon the one hand, and the nutritive state and the temperature sensibility upon the other, there is no connection. The prophylactic measures directed in general toward "catching cold" are not only attended by a directly opposite result, but they further expose the organism to far greater danger than is to be anticipated from disease resulting from "catching cold." Protection against such disease may be secured by increasing the reactive capability to thermic irritants by means of suitable exercises.—*N. Y. Med. Rec.*

A MIRROR OF PRACTICE.

A CASE OF CARCINOMA OF THE RECTUM : 'EXCISION: RECOVERY.'

By ARTHUR NEVE, F.R.C.S.,
Kashmir Mission Hospital.

THE following case is of interest as showing that in some respects the perineal operation of proctectomy is more easily performed in women, specially in multiparae, than in men, but it must not be forgotten that, as ALLINGHAM¹ has pointed out, the peritoneum descends lower in the female than in the male; in the former it is frequently less than 3 in. from the anus, while in men $3\frac{1}{2}$ in. to 4 in. from the anus is the common site for the reflection of the serous membrane. The mortality of the operation is high; it has been given by BUTLIN² as 85 per cent., and by BALL as 165 per cent; the one is probably too high and the other too low.

A Panjabi woman, servant in the family of a distinguished officer, had been ailing for some months but had had great increase of pain since a fall fifteen days before. She was admitted on 7th June 1895. She appeared to be over fifty years of age, and was exceedingly feeble. Much pain was complained of, and there were frequent motions with much straining. Blood, mucus, and pus were passed. On digital examination a tumour could be felt on the posterior aspect of the rectum extending from near the sphincter for a finger's length upwards. Laterally it measured about two and a half inches in diameter. There was a considerable amount of thickening extending upwards with an ulcerated centre. Owing to the comparative accessibility of the parts in a multipara, Mr. NEVE decided to excise by the perineum. The operation was performed on 13th June with the assistance of Dr. ASHTON and Dr. McCULLOCH. The usual lithotomy position was employed. The anus was widely dilated. An incision was carried outside the sphincter for the posterior two-thirds of its circumference and continued back to the coccyx and a little up on the right side. The tissues were rapidly separated in front and on the left side, cutting, where necessary, with scissors; pressure forceps were left on the bleeding points. Separation was then effected on the right side to a point level with the upper limit of the tumour. Thus a strip of the anterior surface of the rectum was left continuous with the sphincter. The attachments of the tumour above proved too dense for the scissor, so they were cut through with scissors as high as the third sacral vertebra. The incision seemed to go through tissue infiltrated by carcinoma, as proved to be the case when the part removed was examined by Stiles' method. Dr. NEVE cut away some nodules that were within reach and also a gland the size of a marble. The pelvis could now be easily explored as the gap admitted the whole hand. A strong solution of chloride of zinc was applied to the raw surface and the wound was packed with gauze, a glass tube having been inserted in the bowel, several pairs of pressure forceps remaining *in situ* till next day. The loss of blood had been considerable. The progress of the

case was uneventful. On the following day the stuffing was removed. Fæces collected in the wound and had to be daily cleared out by syringing with dilute creolin lotion. Ten days later the cavity was fast closing and the wound towards the coccyx narrowing. On 18th July, a month after the operation, the patient was able to get about the ward and the wound was closed. She returned to her mistress in August and in the winter obtained employment elsewhere. When heard of, she was said to be fairly well and at work (April, 1897).

Remarks by Dr. NEVE.—The relief given to the patient by this operation was very striking. At the time I did not consider that the disease was eradicated and the history is not sufficiently complete to prove that it had been. At the operation the view of, and access to, the diseased parts was all I could wish for. To have performed Kraske's operation would have been needlessly severe and would scarcely have afforded any better chance of extirpating the disease. In this case it was not necessary to open the peritoneal cavity. The infiltration was all posterior with dense periosteal adhesions to the sacrum. Had the patient been a man, it would not have been possible to have removed so much through a perineal incision. It is in males and in cases where the tumour is situated anteriorly, or where the peritoneal cavity has to be opened and the whole rectum drawn down, that Kraske's operation is serviceable.

CARBONIC OXIDE POISONING: A SAD TRAGEDY.

By ASSISTANT SURGEON H. D. PANT, L.M.S.
Gonda.

I was hurriedly summoned by the Station Master of Gonda, on the morning of the 15th January 1898. On reaching the place I found four people dead in one room. The room was 10 x 8 x 10 feet with only one side window. The family had retired at night, shutting the doors, coals being burned to keep them warm. When I entered the room it was stuffy and full of the smell of coal gas. The *post-mortem* signs were so similar that the description of one suffices for the four. The heart and lungs were gorged with bright red blood. There was liquid blood of the same color in the cavities of the heart. All the muscle and tissues were also tinged scarlet. A condition once seen, never forgotten.

It is a necessary duty on the part of the Railway authorities to provide pucca rooms for its servants with some proper means of ventilation. A simple opening on the roof or wall would have prevented this sad calamity to a family of four souls, a husband, wife, and their two sons.

ENORMOUSLY ENLARGED SPLEEN AND LIVER DUE TO MALARIA: DEATH: ~~POSS~~ MORTEM RESULTS.

By RAM LALL SINGH, C.M.S.

Camp Line Law, Anglo-Chinese Boundary Commission.

MAH TU, a male Kachin, aged 30, had been admitted into the Bhamo Civil Hospital off and on, during the last ten years, for ague, enlarged spleen, liver, etc.

The patient was of small build with chest, contracted, body emaciated, and shrunken skin, but with an unusually enlarged abdomen.

* Reproduced from the *Lancet*.

1 International Encyclopedia of Surgery, Vol. vi., p. 122.

2 Operative Surgery of Malignant Disease, p. 241.

After this passage, he was admitted into hospital for pneumonia and again from which he recovered, but was shortly after attacked with erysipelas which affected nearly the whole of the body extending from the shoulders to the thighs; from this he also recovered only to be readmitted during the rainy season of 1896 for low fever and jaundice, on which diarrhoea supervened, and ultimately caused his death.

As soon as the body was removed to the dead-house, the chest and abdomen having been laid open and the organs exposed to the utmost, I had a photograph taken of the viscera. The annexed diagram is a fair representation of the photograph and depicts the enormously enlarged liver and spleen.

Post-mortem.—The lungs were displaced upwards and bore marked impressions of the ribs; the heart was also displaced upwards. The liver extended from the right to the left hypochondriac region overlapping the spleen to which it was adherent. It weighed 7 lbs. and was 18" long by 10" broad. The spleen occupied the hypochondriac and lumbar regions, as well as a part of the iliac, pressing upon and displacing the intestines, weight 6½ lbs. The entire body weighed only 53½ lbs.; it will thus be seen that the liver and spleen together weighed rather more than a quarter of the weight of the whole body.

NOSE DEFORMITY AND OBSTRUCTION DUE TO A LARGE RHINOLITH.

By ASSISTANT SURGEON H. D. PATT, L. M. S.

Gonda.

GOKUL, aged 50, was admitted into the Gonda Sader Dispensary on 6th January 1898 suffering from obstruction in the right naris. The obstruction had lasted three years. The right side of the nose was very prominent and the nostril considerably dilated. He was admitted for polypus of the nose. On introducing the forceps the thing felt hard and bone-like, and was with difficulty dislodged and taken out, dilating the nostril considerably. It weighed about 400 grains and was of a flat circular shape 2½ x 2½ x ½. It was sawn through like a bone and was found to consist of much gritty material intermixed with hard inspissated mucus and blood. I send these notes for publication, as rhinoliths are rather rare, and I have never seen one of this size before.

Indian Medical Record.

1st March 1898.

HOSPITAL ABUSE IN INDIA.

THE question of hospital abuse is one that touches us all nearly, and if we have been silent on the subject of late, it is not that our eyes have been closed to the evils which surrounded us.

This abuse is a plant of old standing; it has spread its roots far and wide; it has increased to an alarming size, and its baneful influence extends to everything in its neighbourhood.

Throughout the length and breadth of England and the United States of America, the outcry against it has been growing louder and louder, until at length the cry of Reform has become almost universal.

Associations have been formed with this object, the general practitioners have taken up a determined position, the lay Press has lent its voice, and the Dukes of Devonshire and Bedford have discussed the subject in semi-public speeches.

It is time that the medical profession in India should follow this lead, and take steps to put an end to this abuse, which every year presses more heavily and more unfairly upon its members.

It may be asked, what is this question of Hospital Abuse? Well, in its simplest form it amounts to this, that well-to-do people are the daily recipients of charity, that they stoop to partake of benefits intended solely for the use of paupers, that to a certain extent they are, in fact, robbing the poor.

Now the crime of robbing the poor has, in all ages and in all countries, been deservedly held in special loathing and abhorrence, yet in the British Empire, at the end of this nineteenth century, it thrives and may even be said to be fashionable and very much so in Calcutta, Madras and Bombay.

When a dole of bread is given to the poor, or when a soup kitchen is opened for their use, we do not find respectable people rushing to take advantage of it, though bread and meat are part of their daily wants. No, because no one objects to paying their butcher's or baker's bills.

With the doctor's bill it is different.

Where the question of medicine and medical advice is concerned, people are found ready to abandon all the rules;—we will not say of rectitude and honor; for it would be superfluous to suppose they existed in these cases,—but of that common honesty, by which, under the penalty of ostracism, they are bound to regulate their conduct in all the other relations of life.

That this should be so is a disgrace, and a double disgrace; a disgrace to him who gives and to him who takes. Yet it is so, and in this great city of Calcutta it is a plain and openly acknowledged fact.

In the Indian Medical Gazette for February, which deserves the thanks of all, for the calm and sober way in which it lays its finger upon these evils, we read that "persons who cannot be regarded as paupers, or

In poor circumstances, they who would be disgraced if their social position were questioned where a function at Government House was required, yet have no shame in obtaining medical advice, and even treatment, at a charitable institution. In fact the numbers of private marriages to be seen in front of such institutions is sufficient proof of the circumstances of the owners, who drive up to them apparently without any idea of the incongruous appearance they present."

Now for this scandalous state of things it is perfectly plain that there are three sets of people to blame:

1. The impostors who receive the charity.
2. The Hospital Staff.
3. The ruling authorities who are responsible for the rules of the hospital and their proper observance.

The first are the traffickers in stolen goods.

The second are the Judas Ischariots who rob the poor.

The third are the evil councillors who veil the face of the king.

To veil the meanness of accepting charity, charity intended for others, the first are ready with two excuses, which, though weak, are the only ones that can avail them anything, ignorance and custom. They did not know that they were partaking of what was not meant for them, they did not reflect upon the ugly light in which their conduct might be placed, and, so and so had done so before, why should not they?

For such persons the remedy appears fairly plain and simple.

1. Have a large notice on either side of the portal, setting forth in large letters the object of the institution

2. Make them assemble in a common room and take their turn strictly with the legitimate patients.

When we come to consider the attitude of the hospital staff, we touch upon a question of wider range and more varied aspects.

In one respect it is the old hospital monopoly working against the interests of the general practitioner.

No one can for a moment doubt that a good hospital connection is an excellent magnet to attract a private practice, and of course it may be unduly used for this purpose.

We are told by an American correspondent of the *Lancet*, that a very large majority of the medical practitioners of New York are in favor of a radical change in the methods of conducting the hospitals and dispensaries, and are determined to leave no stone unturned to gain their object, and there can be no doubt but that their efforts in this direction will be crowned with success. On the other hand, it may be said that there is no real desire on the part of the managers of the hospitals and dispensaries to remedy the evil; in fact, it is to their advantage that the present system should continue, so that it is practically a fight between the hospital boards on the one side, who wish things to remain *in statu quo*, and the outside practitioners on the other side, who desire reform, and the position in London does not appear to be very different.

In the Presidency and other large towns in India, however, the general practitioner is in a worse plight, for he has not only to compete with men holding influential posts in

the large hospitals, the influence of which is the more felt in proportion to the limited number of the population, but he is still more heavily handicapped by the fact that all these men are highly subsidized by Government.

Now we know what a clamor is raised when Government tamper with private enterprise in any matter connected with trade, and how the whole "Press" sounds a trumpet call of alarm.

Why then should medical enterprise not be equally sacred.

The time has gone by when this subsidized medical labor was necessary, and the time has come for its abolition. It is an anachronism at the present day when India is able to supply her own wants both through her own medical schools and universities and the recruits it receives from abroad.

Now with regard to the attitude of the hospital staff to this question of hospital abuse, we have it on the authority of the *Indian Medical Gazette*, on whose opinion in this matter we can place the surest reliance, that they do not do as much as they ought to remove it.

"The complaints that some of them have made," it says, "can be answered by the fact that the remedy lies in their own hands."

Cases do, however, undoubtedly arise where they are powerless owing to the rules not being sufficiently strict, or laid down with sufficient definiteness, and it is here that the authorities can step in and put the matter on a proper and satisfactory footing.

A clear representation of the state of the case and of what is required, to the Lieutenant-Governor, would, we believe, be soon followed by a wholesome change.

It has for some years now been the appellation of India that so little has been done to advance medical science. We have had occasion to remark that there no longer exists such a thing as an English School of Tropical Medicine, and where should we look for it if not in India.

In India, however, original research in this direction appears to be dead. The fund of valuable material in our large hospitals and medical schools is wasted. When we turn our eyes in their direction we are not dazzled by the clear light arising from scientific investigation which they diffuse, but by the large incomes arising from lucrative private practice.

"Where the treasure is, there the heart is also." Let us hope that the new departure of prohibiting the Superintendent of the European General Hospital from engaging in private practice, will prove not only the first step in righting a long-felt wrong, but also the inauguration of a new era in Indian scientific medicine.

THE AMOEBAE OF DYSENTERY AND ENTERITIS

CONSIDERING the importance of everything connected with the etiology of Dysentery and Liver Abscess, in a country where these diseases are so common, we are glad to be able to follow up our notice of Dr. Windson's conclusions, (in last issue) with the following admirable summary of the subject from the pen of a well-known German writer.*

* Dr. Friedrich Boemer, translated from the German (*Munchener Medizinische Wochenschrift*, 11th January 1897).

the first case in her pathogenic experiments. In subsequent attempts were made to find the cause of dysentery. Everyone believed that it was caused by the bacteria found in dysenteric stools, and each put forward a number of theories. The first, which the investigation seems to demand, with sufficient justification, is to find the specific cause of dysentery.

In later years Lillie, followed by other authors, in the etiological study of dysentery, has turned to the amoeba and spoken in favor of its being pathogenic.

The search for the cause of dysentery in the bacteriological domain, however, continued in the present time, and in the last years, particularly in the German literature, authors have appeared, who, differing either opinions, attribute an etiological rôle to dysentery to the usually harmless bacillus coli, or at least to a virulent form of this bacillus.

Amongst these the first to be mentioned is ARNAUD¹ who in 80 cases of North African dysentery found, often entirely alone, the bacillus coli either in the stools or in the dysenteric stools; he saw the amoeba, and he was able to produce dysenteric ulceration in cats, by introducing into the rectum 25 to 30 c.c. of a broth culture of such bacilli.

CELLI and FRODA² were also unfavorable to the claims of the amoeba; they produced dysentery in cats with the stools of men suffering from dysentery without amoeba, and also with dysenteric stools after the death of the amoeba; they believe with ARNAUD in the etiological action of a virulent form of the common bacillus coli, and with it they can cause dysentery.

KARVULIS³ was amongst the first to study on an extensive scale the pathogenic qualities of the amoeba; he found it in more than 500 cases of endemic dysentery in Egypt; he produced dysentery in cats, which are peculiarly susceptible, by injecting dysenteric defects into the rectum.

Amongst later investigations, the next to be noticed are those of OBERHOLMAN and LAFLEUR⁴ who found the amoeba in 15 cases of North American dysentery, both in the defects and in the tissue of the ulcerated gut, and in their theses.

KRONE and PASQUARI⁵ in their studies in Egypt found the amoeba in 40 out of 50 cases of dysentery, often in the intestinal wall and in liver abscess. They caused dysentery in cats with dysenteric defects and also with liver abscess pus, and believe the amoeba to be the exciting cause.

VIVALDI,⁶ who in an Italian epidemic found the amoeba in every case, only succeeded in exciting an intestinal catarrh in cats, still he attributes an etiological action to the amoeba.

Out of 158 cases of North African dysentery, GAZEN⁷ found the amoeba 64 times; he does not believe that it is pathogenic, he observes that a dysenteric-like process takes place after the introduction of sterilized garden earth into the rectum of cats.

Mayer's observations extend to 17 cases in adults and 1 of dysenteric inflammation of the intestine in children; these cases originated in tropical and sub-tropical climates, the blood in the stools, the characteristic

excretion of mucus, and the other symptoms, were all present in the majority of cases.

These cases, which did not differ from those already noted, must be considered as dysenteric, and the amoeba, for it appeared in the stools, and the excretion of blood and dysentery brought the case of the dysentery.

In distinguishing between cases of dysentery and amoebic dysentery in temperate climates, there is first the stool, upon the examination of which the amoeba, but blood appears in the stools in other cases, and is sometimes present in dysenteric stools.

The only reliable distinguishing sign is the amoeba, the exact exciting cause of dysentery is as yet unknown to us.

It is easy to demonstrate the amoeba. Remove a small piece of sticky matter from the stool with a platinum needle, and examine it at a temperature approaching that of the body, a hot "stage" on the rack, with heat the amoeboid movements will last a long time; fix the freshly spread preparation with a saturated solution of osmic sublimates, then harden with alcohol and stain with logwood and eosine.

The movements of the amoeba and their characteristic nature are easily made out.

The glassy appearance of the ectoplasmic shell can be seen in a good specimen, as well as the flowing motion of the endoplasm, the vacuole, and the small round nucleus, while the appearance of enclosed and blood corpuscles is well-known.

The demonstration of motile amoebae presents no difficulty as a rule, in stained preparations the amoeba, from its substance, form, and size can usually be overlooked.

(The details of the cases are omitted).

In all the cases classed clinically as dysentery reported into the hospital in the period from March 1894 to October 1895, which for the most part were brought from foreign countries by trading vessels, or came sporadically in Germany, I have been successful in demonstrating the amoeba, in cases from Africa, the East Indies, North and South America as well as in those of European and German origin.

As a rule, especially in cases from tropical countries, the amoeba could be seen in pure culture; in the cases where they were not, they could be distinguished in fresh and in stained preparations.

I am not in a position however to state any characteristic, by which a distinction can be drawn between the amoeba of the so-called tropical and European dysentery, will be found in the stool, the mucus, the substance or in any other feature, for in cases of enteritis, where there was no blood, the amoeba was found in the slime of the stools which could not be distinguished from those of dysentery.

The absence of amoeba, especially in cases of dysentery in such cases is explained by the fact that very few of the latter were present in the stool.

There is a very striking difference in the size of the amoeba in some cases, which are not infrequently very distinctly emphasized; sometimes they are very small, more common in all cases, and usually a moderately colored mucus, large amounts of mucus, and dysentery.

[illegible]

It is also worthy of notice, that in my researches I observed very large CHANCOI's crystals in dysenteric stools.

No. 14.

THE MADRAS SANITARY REPORT FOR 1896.

This is a very well got up Report, and contains a store of useful information concerning all that pertains to sanitation in Madras.

A special feature to be commended is a large number of compact diagrams, comparing the birth and death rates, with those of food and rainfall in the different districts.

The estimated population for the year was 36,655,033.

In rural areas, the birth-rate was 28.7 per 1,000, and the death-rate 17.8 per 1,000. In Municipalities the rates were respectively 23.2 and 28.2 per 1,000: all calculated on the estimated population.

The infantile death-rate was 188.0 per 1,000 in rural areas and 233.9 per 1,000 in Municipalities.

Steps have been taken to make registration under these heads more effective, and penalties have been inflicted in 950 cases.

We could wish that the circular tables, showing the birth-rates and death-rates in each registration circle were printed in such a way that they could be read from one point of view, without the necessity of turning them round.

Cholera accounted for 47,847 deaths during the year, or 1.3 per 1,000 of the estimated population; the districts chiefly affected being Bellary and Coimbatore; it is pointed out that this disease has a marked seasonal character, its maximum incidence coinciding with the monsoon periods.

As there are two monsoons, the North-East and the South-West, this relation is more clearly established; for each place suffers most during the monsoon to which it is most exposed.

An excellent cholera map is given, showing by different densities of coloring the different degrees to which the disease prevailed in each place.

The largest mortality is returned under the unsatisfactory head of "fevers," the figure being 260,769 or 8.0 per 1,000; the next highest figure after cholera is 24,802 or 0.7 per 1,000 from dysentery and diarrhoea.

We learn that the mortality from "fevers" has not been so low since 1891, and that both these years (1891 and 1896) of comparatively small fever prevalence were marked by deficient monsoons "in the ceded districts where malarial fevers are largely prevalent."

The subject of "fevers" in the whole of Madras and their causation is a subject on which a good deal of light has still to be thrown.

If anything were required to impress upon our minds that water is at the present time the fashionable mode of conveyance for all diseases, we would find it under the head of sanitary works. We find a formidable list of water-supply schemes, either completed, in course of construction, or about to be undertaken.

From a table on page 46 "inserted by order of the Government of India," we are able to judge of the benefits derived from the water at any price policy, commenting on the facts set forth in the table, the Sanitary Commissioner says: "It cannot be said that the results acquired so far are very striking."

We, however, think that they are very striking; for we cannot find that any benefit has accrued from these water works, though some of them have been completed a good many years.

It is of course easy to find objections, but the facts are solid facts; a large amount of money has been expended and there are no results, the policy on its own showing stands condemned.

A good water supply is no doubt a very excellent thing, but it does not seem to hit at the root of disease in Madras, doubtless it is not the whole of sanitation, and there may be other and simpler things which might be attended to first. It is useless to polish the diamond before it is cut.

"Fever" are the chief source of mortality in Madras; it is not suggested that they are waterborne; the first thing to do to lower the mortality is to find out their cause and then take steps to remove it.

In one place Kerur, (Coimbatore) we notice that the water supply scheme is to take precedence of the drainage scheme, which is postponed; this, we think must be contrary to the advice of the Sanitary Commissioner, and it is certainly opposed to common sense sanitation to bring water to a place without taking steps to remove it is certain to induce disease.

In Table II, Appendix D, under the head of "Principal Sanitary defects of Circle" there is a list of sanitary shortcomings, which it is impossible to exaggerate, unfortunately the condition is common to the whole of India.

To cope with such a state of affairs would afford plenty of scope for the most energetic Sanitary Commissioner, and a staff much beyond what is known in this country.

The column headed "Drainage" loses much of its value from the indefiniteness of the term. Drainage is one thing and sewerage is another, and it would be well if the two things were kept separate.

Dr. KING only perpetuates the legal technicalities of the English Public Health Act by talking of "house drainage."

In England we know that the pipe that carries sewage from a house is a drain, while the pipe that carries it from a town is a sewer; but would it not be well in the country to do away with this absurd distinction and call every channel for the conveyance of sewage a sewer? Under the head of "Personal Proceedings," the Sanitary Commissioner says, "Of the total of 365 days, I was absent from headquarters on inspection duty 210 days. During this period, I travelled 9,784 miles by road, rail and canal."

Now we think that a Sanitary Commissioner, whose time is thus taken up, is not only an overworked man but that his services are not utilized to the best advantage by the Government.

KHAN BAHADUR CHOKEY'S PLAGUE REPORT.

A very able and lucid "Report on Bubonic Plague" has been issued by Khan Bahadur N. H. CHOKEY, Extra-Assistant Health Officer, Bombay, Municipality.

The Report is based upon observations of 939 cases of Bubonic Plague treated at the Arthur Road Hospital, Bombay, from 24th September, 1896 to 28th February, 1897. In addition to its importance from a medical point of view, it illustrates in an interesting manner the attitude and prejudices of the natives in regard to the Plague, and the measures taken to combat it, which

SECRET

The three entrances to the Indian Hall Hospital, which consists of three open sheds with a stone path and a stone wall with stage ventilation, supported on iron columns and wooden flooring. They are usually closed by iron doors and metal frames. The size of each of the sheds is 111 by 40 feet.

“At first, we are told, ‘came in the good deal of air-ventilation,’ and that ‘opinion was pretty equally divided amongst the savants as to whether a permeable and frequently renewed flooring, or an impermeable and permanent one was best for a tropical climate.’ Subsequently, ‘one shed was experimentally paved with Indian Forest Stone.’”

A vivid description is given of the efforts of the much overtaxed institution to meet the unprecedented and daily increasing claims of the epidemic, and special attention is called to the difficulty of getting servants. "Pay, however large, was no inducement." The terrifying sights and sounds and the large mortality of a plague hospital were too much for them, and many after working a short time fled in terror.

In spite of these difficulties the staff struggled bravely on. "The strain," we read, "was terrible, and it is indeed a source of wonder when thinking calmly over those days to realize how the whole staff passed safely through such critical times."

The generous devotion for which the medical profession is justly celebrated, was not wanting in those trying days, and we are proud to record the names of Doctors PILGAONKAR and Miss MANECK TAKKHAU who, Khan Bahadur CHOKSY says, "volunteered to assist me during the most trying period of the epidemic, and I cannot sufficiently thank them for the valuable aid they rendered me." Doctors MOON and C. F. UNDERWOOD also assisted me for a short time."

Nor must the nurses be forgotten. These important duties were placed in the hands "of the Sisters of All Saints on the 6th of February, and no words could suffice to eulogise the devotion and zeal they brought to bear on the nursing of plague patients at no inconsiderable personal risk and sacrifice." Miss ATKINSON, of Cama Hospital, also joined the Sisters in this work, and Mr. RICHARDSON, F.C.S., F.R.S., assisted for a considerable period in nursing the patients."

The mortality was very high—78.26 per cent. This was in part due to "the ignorance and prejudice of the people always averse to going to a hospital." So that many patients were brought in a dying condition, when it was too late to do anything for them.

If the number who died within the first 24 hours after admission is deducted, the percentage death-rate is brought down to the respectable figure of 60-84.

The simplest native mind, always apparently ready to attribute the worst motives to what they cannot understand, understood, nevertheless the object of the hypodermic injections, given to resuscitate and support the strength of the sick; and it was openly stated that the doctor was killing the patients in order to stop the further ravages of the epidemics. It was also freely said that the

patients were purposely killed for their blood taken out in order to send them to King Molyang, the Queen-Empress, to appease her wrath, on account of the disappearance of her statue, which occurred at the beginning of the epidemic." These miserable ideas, the outcome of the ignorance of superstitious peasants, manifested in a riot on the hospital in the morning of the 20th October 1926, when a large number of peasants, estimated at from 600 to 1,000 rushed to the hospital, with a view to wreck their waywardness on the hospital staff for the alleged killing of patients."

Thus these zealous workers, in the midst of all their anxious troubles, were in danger of being martyred by those to save whom they were risking their lives.

In this dreadful time all the natural feelings of affection were lost amongst the afflicted population, the ties of relationship, no matter how close, seemed to touch the heart; husbands were deserted by their wives, wives by their husbands, and little children by their fathers and mothers. People bringing sick to the hospital gave wrong addresses to avoid recognition, their only desire being to escape all further responsibility.

The master passion of cupidity however survived and the greater part of those who ventured into the hospital, did so with the object of removing the last ornaments from the bodies of the dying.

Of the hospital staff Dr. P. W. DAVNA and three ward "boys" contracted the disease. The former, we learn with regret, succumbed a martyr, dying in the service of others; the others had mild attacks and all recovered.

The remainder of the Report is of a more technical character.

It was noted that people who were better fed had a better chance of recovering than the worse fed.

The types of plague are classified as follows :-

1. Pestes' minor, or extremely mild plague.
2. Pestes' ambulans.
3. Pestes' simplex bubonica, or simple bubonic plague.
4. Pestes' septica or septic plague.
5. Pestes' pulmonalis or pneumonic plague.
6. Non-typical forms of plague.

"Besides the above, two other forms have been mentioned. Abdominal and laryngeal." Cases of these types were not observed.

Types 3 and 4 are particularly characteristic of plague, and their difference is rather a question of degree than of kind, "depending, as it does, upon whether the plague bacilli infect or do not infect the blood."

"So long as the bacilli are confined to the lymphatic system alone, without infecting the blood, the case may be called simple bubonic, but once the blood is infected and graver symptoms develop, the case becomes septic."

In the pulmonary form "it is assumed that the pneumonia is primary. In some cases, however, of undoubted primary pneumonia, all efforts to discover the presence of a tube during life failed, but on post-mortem examination, deep-seated axillary tubercles were found." It is therefore debatable whether these glands were primarily or secondarily affected. The sputum in these cases is loaded with bacilli and forms a possibly fertile source of the spread of the disease.

Method of infection.—In spite of the preponderance of femoral and femoro-ingual buboes, not more than 5 per cent. could be traced to direct infection through breach of the skin; although most of the patients admitted, had numerous cracks and fissures on the soles of the feet and elsewhere, and had gone bare-footed all their lives, "yet traces of inflammatory mischief from the absorption of the virus through the crack or fissure were conspicuous by their absence."

Infection may also take place by inoculation with the pus from buboes, which at first contains a large number of bacilli, through the sputum, and through inspiration.

"It has not yet been ascertained in what proportion of cases the excreta contain bacilli," the Austrian Commission examined a large number of cases carefully, but were not successful in demonstrating the bacillus.

Incubation.—The incubation stage, as a rule, was found to be from three to six days.

The aspect and speech were always characteristic, sufficiently so in most cases for the formation of a diagnosis. The facies Pestica presents a mixture of "dread, anxiety, and resignation."

The speech was of two kinds, in one "it resembled that of a man under the influence of drink, the words being broken up into syllables, and each syllable articulated with some difficulty and hesitation, and in a more or less thick or husky tone."

The temperature from the first day rises gradually, attaining the maximum on the second, third or even fourth day." The natural course of the fever is that of morning remission and evening exacerbations with a difference of 1 to 2 degrees.

Much of interest will be found under the head of Delirium from which we quote the following:—"Some patients used to show a peculiar fondness for a particular bed, either that of a neighbour or of some patient at a distance, and would get out of their own bed and try to lie down beside the other patient, doing so quietly, or in the act falling heavily on the occupant. Another patient would fancy no better position than lying underneath somebody else's bed. In one instance a strong, powerfully built man climbed up one of the iron columns supporting the roof, and was only brought down with great difficulty."

We regret that space does not permit of our giving this valuable Report in greater detail. We can heartily congratulate Khan Bahadur CHOKRY on an excellent piece of work, to which we recommend all readers interested in this important subject.

The Report is very well got up, it extends to 57 pages, and has a number of clinical charts attached. It is printed by the *Times of India Press*, Bombay.

HERNIA.

WHILE admitting the value of operative interference in hernia, C. F. SOUDER favors injecting the site with 2 to 4 minims of a mixture of Zinc Sulph. gr. ii, Creosote m.iii, Fl. Ext. Hamamel m.xxx, and Glycerine m.xxx, for which he claims the following advantages over operation: (1). Simplicity, safety and efficiency. (2) Anæsthetics and laying up not required (3) Quicker and much larger percentage of permanent cures, and incurable (?) cases can be made comfortable, obviating risk of strangulation. (4) No mortality. (5) Size and duration make no difference, and in simple cases one injection suffices.—*Medical World*.

COMMENTS AND NEWS.

FORCIBLE STRAIGHTENING OF THE SPINE.

AMONGST the most startling of recent innovations in surgery is the new method of forcibly straightening the spine for the cure of Pott's disease, upon which an interesting discussion was recently held by the Clinical Society of London.

Dr. P. REDARD (Senior Surgeon to the *Parcels' Office Dispensary, Paris*) contributed a paper in which he states:—"I am a warm partisan of the immediate reduction and assailing of the curvature in Pott's disease in certain cases. My practice of this operation during the past year, amounting to 40 cases, has convinced me that this method, employed with prudence in proper cases, is practical, efficacious, and exempt from danger. All cases of curvature in Pott's disease are not amenable to immediate reduction. Only those curvatures can be corrected without danger in which reduction is easy, or comparatively easy, by slight traction applied to the two extremities of the spine, or by slight direct pressure applied to the boss itself. The correction of irreducible ankylosed curvatures exposes the patient to serious complications, and is not to be recommended. Immediate reduction is indicated in reducible curvatures of limited extent, short radius, and rapid development, also those complicated by paraplegia of rapid onset. Duration of existence, size, and extent of the curvature are not to be regarded as contraindications. The only contraindications, in my opinion, are irreducibility with the employment of moderate force or traction, a bad general state of health, generalised tuberculosis, visceral disease, and large cold abscesses."

He employs an apparatus by which the tension is made gradually by means of a screw. Chloroform is, as a rule, unnecessary.

"After reduction I employ a plaster corset, including both the trunk and the head. The plaster bandages are usually applied directly to the skin, but in some cases a jersey or a very small quantity of wool is used. My experience has taught me that a large quantity of wool applied to the trunk beneath the plaster is unfavorable to the safe retention of the spine in position, may result in a redevelopment of the deformity, and exposes the patient to the danger of pressure sores over the angle of the boss if this be not fully reduced. If the plaster corset is well applied, the spine is held in good position, and the cephalic portion of the apparatus may be omitted, especially in lower dorsal and lumbar curvatures. In the whole number of forty cases of varying duration and severity that I have treated, no complication, either immediate or remote, has been noted, and I have observed many severe cases in which definite correction of the deformity has been obtained. Prolonged immobilisation in good position in a corset of plaster-of-paris after the reduction of the deformity, is absolutely favorable to the cure of the disease."

These roseate views are not held by other surgeons.

WATSON CHEYNE acknowledged that the immediate effects were not so serious as he would have expected, but added the following objections:—"The forcible straightening of a tuberculous joint was apt to give rise to general tuberculosis, and the lighting up of acute local inflammation. A cure could not be said to have taken place in these cases of straightened spine until (1) the tuberculous bone disappeared or became encapsuled, and (2) bony ankylosis followed, which was not to be relied upon. Until then, these patients were not out of the wood. Ankylosis was a slow process, and probably took two years for its accomplishment in many

cases. Cavities must be left in front of the spine by the straightening, which must be filled with blood clot, fragments of bone, and chondry material. These conditions would not encourage the formation of new bone; and the vascularisation of the bone must be (theoretically) imperfect. Would ossification occur between the bodies of the vertebrae? Most surgeons would answer that question in the negative. In tuberculous disease of bone one found very little new bone between places around the infected area."

That these objections are not merely theoretical is well shown by two cases published by R. W. MURRAY, F.R.C.S., of Liverpool.

In these cases death occurred in the first 51 days after operation from pneumonia, and in the second 87 days after operation from meningitis.

It was shown post-mortem that there was not the smallest evidence of repair, in the first case the gap formed by the straightening had resolved itself into a "false joint" bounded by caseous and diseased tissue; in the second there was no attempt at the filling in of the gap.

Most surgeons will be inclined to agree with the opinion expressed by WATSON CHEYNE, that this new method of treatment was not likely to come into general use in cases of spinal deformity.

"It was now on its trial, and should at present be used in a very limited number of cases. Enough had already been done to enable them to form an opinion when the results would be known some two years hence. Meanwhile, let them avoid further operations, for the patients' good, and for the good reputation of themselves and of surgery."

THE SECRET OF SEX.

PROFESSOR SOHNKE, of Vienna, who claims to have discovered the secret of the production of the sexes, has given the following interesting particulars, in an interview with the London correspondent of the *New York World*.

In reply to an enquiry if he could give positive and direct information regarding his treatment of women desirous of giving birth to boys, he said—

No, I cannot do that, I gave the treatment under seal to the Imperial Academy of Sciences in Vienna, where it will be proved and published. But I can communicate to you the results of my discovery, and give you the scientific facts upon which it is based.

If I say I can determine the sex of a child to be born, you must understand this. I can ensure that a woman gives birth to a boy, not to a girl, my treatment has no other aim than causing boys to be born.

It is my own choice that by my marriage I have had six sons. I have achieved similar results in the families of relations and friends—fourteen cases in all. I cannot trust every strange woman I see, I must be able to watch her and be certain that my prescriptions are rigidly obeyed.

According to my discovery, the man has no influence whatever on the sex of the child. All depends upon the woman.

My discovery is based upon the scientific fact that the blood of a grown-up man contains five million blood corpuscles, while the blood of a woman contains only four million. This difference is the basis of the difference of sex.

This proportion is observable in the slightest quantity of blood from a man or woman. All my efforts are directed towards producing the right number of blood corpuscles required by the male in embryo. I have succeeded in attaining this effect by suitable nourishment of the woman."

In reply to a question, writes the *Medical Times and Hospital Gazette*, the Professor said—"I am no man of

business, but am exclusively a scientist. I am not anxious to gain a fortune, but above all that my discovery be scientifically confirmed and recognised. The Academy of Sciences alone can do this. I have accepted no reward in the successful cases I have treated; they are precious to me beyond gold as proofs of the reality of my discovery. I have achieved such success in a family in which all the most intense desires were directed towards the birth of a son. If I told you the name of the man in question you would know that for him to pay me 30,000 florins for my service is the same as when you pay the doctor five florins for examining your throat, but I did not accept any reward."

There is only one public personage in Austria to whom all these indications point. He is a member of the Imperial house—Archduke FREDERICK, nephew of old Archduke ALBRECHT, at whose death three years ago, he inherited the colossal entailed property, because Archduke ALBRECHT left only one daughter and no son. The property consists of extensive land, forests, mines, of ironworks, and factories, well known to be worth more than 300,000,000 florins. Archduke FREDERICK during ALBRECHT's lifetime lived upon his allowance. In 1878 he married a portionless Princess, who had since given birth to eight daughters, one of whom died. At every birth a son was anxiously expected. Every medical authority was consulted, and all remedies were applied; the Princess was treated with every care, but all in vain. Every fresh birth brought another girl. In 1895 Archduke FREDERICK became the possessor of an enormous fortune, for which he had no heir. The Princess was resigned to her fate. The Prince could not hope to leave the property to a son. Imagine his joy when, in July 1897, after nineteen years of married life, the Archduchess, in her forty-first year, gave birth to a son and heir! It is undoubted, from the nature of Professor SOHNKE's words, that he was consulted by Archduke FREDERICK, and undertook the treatment of the Archduchess, which he supervised with complete success.

SUB-SOIL AND DISEASE.

IN continuation of the remarks on this subject in our last issue, we give the following very apt illustration from the *Times of India*.—"A good many people in Bombay are awaiting with interest the report of the Committee of the Corporation on the sub-soil water question. Meantime, those who attribute our insanitary troubles largely to a polluted and rising sub-soil water will find confirmation for the belief in a remarkable paper on the history of typhoid fever in Munich, which was lately read by Dr CHILDS before the Epidemiological Society, in which what looks like a very close connection was established between soil pollution and typhoid. Munich has had a bad record in regard to this particular disease. The mortality from it fell in successive decades since 1850 from 202 per 100,000 inhabitants to 148, 116, and 16 in 1880, when epidemics of typhoid ceased in Munich, and in the last three years there have been only 3 cases per 100. The first impulse on a view of these figures is to attribute the marked improvement to improved water-supply. But the sanitary conditions and history of Munich warrant no such inference. In the severe typhoid epidemic of 1855, the population supplied with pure water from the mountains suffered as badly as those who drank from the old wells, and in 1884 the twenty thousand people who still used the old wells suffered no more than those who drank from the public pipe-supply. The improvement is attributed to the improved conditions that were brought about when orders were given for every cesspit in the city to be lined with cement. The sub-soil conditions of the city have by

Dr. H. W. CHAMBERS, for many years H. M. Officer for Salonta, has since compulsion retired from this career and important judicial office under the 32 years rule, and his place has been given to a Bahaduran magistrate. We cannot resist the opinion that the change is most unfortunate. Under no circumstances should any one but a medical man hold the position of Officer. The new incumbent may be a good lawyer and a good magistrate, but none except a doctor should fill a distinctly medical post. There is one thing to be said about the appointment. The salary is not worth having, and the wonder is that a gentleman of Dr. CHAMBERS' high professional attainments and otherwise practical was engaged for the office. No other medical man of position, we believe, would be found to

take the Government within the humanitarian attitude to it was interrupted. We believe we are not singular in our opinion when we say that the Governor should not be a magistrate, and that his functions must of necessity centre his action in civil office. The ends of public justice and the safety of human life from the many infectious forms of bacterial infection demand a change in the present arrangements of the Government of Calcutta. We hold that the Governor should be a medical man, and we further maintain that the Governor should not hold dual office.

TOTAL EXTERMINATION OF THE HUMAN STOMACH : RECOVERY. A UNIQUE CASE.

DR. CARL SPRUELLER, at Zurich, in Switzerland, on the 4th September 1897, completely removed the stomach from a woman aged 56 years, for malignant disease. We have information that on 9th December 1897, three months afterwards, the woman was alive and well, that she had gained weight, that her appetite was good, that she relished her meals, that her taste was unimpaired, and that her bowels acted normally once in twenty-four hours.

On the removal of the stomach, the continuity of the alimentary canal was restored by stitching the œsophagus to the jejunum.

This certainly is a wonderful result, and it is difficult to say whether it is more wonderful from a surgical or from a physiological aspect.

Many will learn with surprise that it is possible not only to live without a stomach, but even to eat, drink and be merry, to feel hungry and even to vomit.

Vomiting without a stomach is certainly a novelty.

As regards digestion, we learn that the albumins of the food could be digested without the aid of the gastric juice. From all this it is obvious that the importance of the stomach and its digestive functions have been hitherto rather overrated.

PLAGUE IN BOMBAY.

THE *Times of India* gives the following as the plague mortality of the nine weeks of the present epidemic contrasted with the mortality of the first nine weeks of the previous epidemic :—

1897-98.		1898-97.	
Week ending 14th Dec.	95	Week ending 20th Oct.	81
" 21st " ... 158		" 27th " ... 119	
" 28th " ... 300		" 3rd Nov. ... 159	
" 4th Jan'y. ... 802		" 10th " ... 120	
" 11th " ... 480		" 17th " ... 187	
" 18th " ... 651		" 24th " ... 238	
" 25th " ... 824		" 1st Dec. ... 358	
" 1st Feb. ... 927		" 8th " ... 458	
" 8th " ... 1,114		" 15th " ... 777	

This table shows the degree of strength of the disease in the two epidemics. The number of plague deaths in the nine first weeks of the last plague was 2,890, while those in the same weeks in the present plague have amounted to 4,780. The present epidemic is therefore twice as severe as the epidemic of last year. It adds, it is as strange as unexpected that the low caste, or no caste, Hindus should exhibit such a comparative freedom from plague as they do. With a population of 45,169 these plague deaths have been only 49, or only about two-thirds of the 81st deaths.

Only two Europeans have died of plague in the present epidemic.

MOFUSSIL PLAGUE STATISTICS.

THE returns for the Presidency for the week ending February 11 give the following results :—Surat District—190 cases, 186 deaths; total 4,910 cases, 2,841 deaths. Thana

District—82 cases, 25 deaths; total 4,950 cases, 2,807 deaths; Poran District—57 cases, 51 deaths; total 11,238 cases, 6,350 deaths. Satna District—190 cases, 148 deaths; total 24,146 cases, 11,051 deaths. Nank District—51 cases, 41 deaths; total 1,588 cases, 1,346 deaths. Alnapore District—195 cases, 166 deaths; total 2,888 cases, 2,367 deaths. Akmetnagar District—39 cases, 28 deaths; total 321 cases, 274 deaths. Khandalah District—43 cases, 14 deaths; total 138 cases, 121 deaths. Kolaba District—54 cases, 38 deaths; total 1,461 cases, 1,356 deaths. Belgum District—40 cases, 38 deaths; total 976 cases, 803 deaths. Barmaherry District—3 cases, 3 deaths; total 154 cases, 138 deaths. Dharwar District—3 cases, 2 deaths; total 49 cases, 45 deaths. Baroda Territory—188 cases, 180 deaths; total 1,532 cases, 1,181 deaths. Palanpore—32 cases, 28 deaths; total 1,515 cases, 1,002 deaths. Kolhapore and Southern Mahratta Country—57 cases, 46 deaths; total 538 cases, 374 deaths. Ebor State—1 case, 1 death; total 34 cases, 16 deaths. Aundh State—21 cases, 18 deaths; total 886 cases, 598 deaths. Cutch—35 cases, 18 deaths; total 5,763 cases, 5,800 deaths.

MODERN HYGIENE AND THE PLAGUE

SAYS the *Times of India*.—"When the story of the Bombay plague visitation comes to be written, it will be something more than a mere melancholy chapter in the history of the human race. Terrible as the mortality undoubtedly is, humanity may yet be allowed to make a serious comparison with the past; and if this be done, it must be admitted that medical skill and a knowledge of the true principles of hygiene and sanitation are forces to-day which exercise a marvellous influence over the destinies of communities. For the scientific and reflective portion of mankind the foregoing proposition requires little demonstration, but people do not always stop to reflect, criticism has no difficulty in making itself heard, and pessimism too often it may be refuses to look beyond the shadow of to-day. While the relative efficacy of segregation, or of quarantine, or of inoculation or disinfection may still afford matter for differences of opinion, the broad question whether man to-day is better able to combat the ravages of plague than heretofore can be answered not only in the affirmative, but it can be answered in a manner which may well make each worker in plague suppression feel that, amid the weariness of continued effort, he is an agent on the path of progress.

BAD MANAGEMENT ABOUT THE ENGLISH PLAGUE DOCTORS.

THERE appears to have been a slight hitch in the working of the arrangement by which the medical men appointed by the India Office for special duty in connection with the plague are being distributed to their respective posts in the Bombay Presidency. Most of these gentlemen, as is well known, have distinguished themselves in various branches of medical research, and as thoroughly qualified specialists it might reasonably have been expected that their services would have been requisitioned by the Bombay authorities almost on the instant of their arrival. So far is this from having been the case, that for a number of days the specialists who landed from the mail steamers week by week were kept dangling attendance in Bombay finding no preparations, and apparently no immediate occasion for their services. Even at the present moment a considerable number of them remain in Bombay in a state of enforced idleness. This is especially hard on them as they were in the majority of cases called upon to leave England at exceptionally short notice, which in one instance extended only to two days.

ARRIVAL OF PLAGUE DOCTORS AND NURSES.

The mail steamer *Fraser* which arrived in Bombay last Saturday, brought the following doctors for plague duty:—*Miss (Dr.) Alice M. Condon, Miss (Dr.) T. Christie, Miss G. I. Blackmore, R. Hornsbach, R. Laing, H. D. N. Macdonald, William A. Justice, C. F. Parsons, G. H. Smith.* The lady nurses are:—*Miss M. E. Payne, and the Misses M. L. Barrow, L. Forbes, C. A. Brown, M. Campbell, Maud Murphy, E. H. Gunning, Jane Ann Evans, Alice Richardson, Ellen Smith, Jane Snowden, Alice Baileys, Emily E. Bradshaw, E. Kiley, Frances Fry, Blanche S. Wood, Katie Cracknell, Dorinda B. Hyland, Milner Scott, M. M. Gardner, M. Hodges, E. Grierson, M. E. Harvey, M. E. Chick, and E. L. Bleaney.* The newly-arrived doctors and nurses will be allowed an opportunity of studying plague in the different plague hospitals in Bombay before any arrangements are made for their distribution in Bombay and in the mofussil.

PLAGUE IN THE DECCAN: DOCTORS URGENTLY NEEDED.

FROM the latest reports to hand, it appears that the plague has attacked several villages in the Beder and Gulburga districts, and the situation is now considerably worse than before. Cases have broken out in Ajunta and Aurungabad, where the police are insufficient to enforce the plague measures. Three hundred troopers of the Hyderabad Contingent from Aurungabad will be placed on plague duty to protect the Nizam's frontier and also to search the country forty miles around. The Plague Commissioner has applied for the services of Captain ARMSTRONG, 8th Madras Lancers, as Secretary, on the score of the increase and heaviness of the work. Ganjote, Umergh, and two other villages in the Nuldroog district show a daily mortality of six cases. In some villages, the people repudiate all idea of plague, even when it has actually been discovered. There is a great demand in Hyderabad for medical men prepared to go on plague-duty.

TANNING IN INDIA

IN reviewing the huge dimensions attained by this industry in India, whence over forty million hides are annually exported to Europe and America, *Capital* points out that, though the trade admits of further development on a larger scale, there is a popular fallacy of the superiority of English to Indian leather, which leads to people paying a better value for the former. Tanning materials are plentiful in India, who exports a large quantity of them to England, and it stands to reason better results are obtainable from the fresh article than from the same article after dryage and deterioration by the export voyage. Recent comparative experiments made in England proved to the full that artillery harness made at Cawnpore, N.-W. P., from Indian leather was much stronger and lasted longer than the same made in England from home-produced leather. While Cawnpore is the centre of a very great leather industry—still however in its infancy—Madras is far to the front in the foreign export trade in tanned hides and skins, for which the Indians largely on the other provinces, as Southern India produces an enormous quantity of superior tanning barks.

THE YUNANI MEDICAL SCHOOL AT DELHI.

THE above school appears to be gaining ground under the principalship of Hakim ABDUL MAJID KHAN. It started in 1866 with 70 pupils, to 45 of whom it has granted diplomas of *Shams*, and it now numbers 180 Mahomedan and Hindu students, who are intended to supplant the untrained hakim class and to revive the nearly defunct (through neglect of ancient and modern sciences in the chase for novelty) system of medicine that earned high laurels in the wars of the Crusaders and

flourished during the reign of the Mogul Emperors. In addition to theory the students have a practical training of 2 to 5 hours daily, during which they see between 200 and 400 patients, most of whom are treated gratuitously. In appreciation of the good this institution is doing for Delhi, the Municipal Committee have assigned to it a monthly grant of Rs. 100, which His Highness the enlightened Nawab of Rampur has supplemented with a house of Rs. 5,000 and a grant-in-aid of Rs. 100 per mensem.

THE LATE DR. R. C. CHANDRA'S WILL, AND THE PROBITY OF HIS HINDU RELATIVES.

SUBCOM-MANOR R. C. CHANDRA, M.B., B.S., L.S.A., Lond., I. M. S., was a native Christian, converted and baptised at Duff College, Calcutta. He was a successful physician and professor of materia medica. He married a sister of the present Lord Chesham, the Earl of Halsbury. He died childless. His wife died shortly before him. At his death it was discovered that he made a will by which he left £500 to the Scotch Mission General Fund and £300 to the little church in Calcutta in which he often worshipped. This will, however, was not signed, and therefore the whole of his property went by law to his unconverted Hindu relatives. The mission authorities renounced all hope of the intended bequests. Remarkably strange, for relatives under such circumstances, and immensely creditable for non-Christians, the Hindu relatives loyally and faithfully carried out Dr. CHANDRA'S wishes. They have made over the sums of money bequeathed to the Mission. All honor to the Hindu Community for such an act of moral probity.

CAN REFUSE TO SELL COFFINS.

IN the *last* BREWSTER vs MILLER the Court of Appeals Kentucky decided that an undertaker is not bound to furnish articles necessary for burial, when the person asking for the same is indebted to him for previous services, and it also holds that it is not unlawful for undertakers to afford mutual protection against such persons by associating themselves together, and agreeing to refuse to render a like service to one who has refused or failed to pay such expenses in the past to some member of the Association. The Court, moreover, rules that any one has a perfect right to decline to enter into a business undertaking with anyone. This may seem well enough, but supposing that by some Act of God the person indebted for burial services is rendered insolvent and unable to fully discharge his first obligation when a second member of his family dies, will the State dispose of the cadaver and levy the costs 'by distress' on an already over-distressed person, or will the corpse be left unburied till its living relatives can raise the funds to inter it?

DEATH OF A VETERAN MEDICAL MISSIONARY.

WE much regret to record the death on the 13th February of the Revd. PEACHY T. WILSON, M.D., of the American Episcopal Methodist Church at Sitapur. He was born in Kentucky, U. S. A., in 1832 and entered upon mission work in Oudh in 1863, with a sturdy band of workers, of whom Bishop THOBURN, Revd. I. H. MANNING, and a few others are still remaining in the field. He graduated M.D., in America in 1877 and did valuable and noble work as a medical missionary. Medical missions in India are a very pronounced success and there can be no doubt that men of the stamp of WILSON, the NEVINS, HUNTLEY, VALENTINE, and others who are now at their great and noble task of missionizing India, are an inestimable source of blessing to thousands of the suffering poor of India, while their holy calling is greatly enhanced by their power and ability to administer to the ailments of the body, as well as to point to the Source of all spiritual comfort and peace.

Saghal: Khar, C.M.S., Camp Khar, Malabar.

Moving Column, Camp Khar, Malakand.

The Chairman of the Executive Committee of Postoffice Subcom is the General Administrator of the Postal Service. In the opening call, the Chairman of the Subcom stated that he was a newly appointed member of the subcom and that it is fairly understandable to have a few members who are new and increasing in number. He stated that he was not the oldest man of this place and that he was not old in the thinking of his staff, and he stated that he was looking forward to it to be satisfied with the work.

BOOKS FOR THE LONDON M.B. EXAMINATION.

The following text-books for the M. B. London Examination are in general use by candidates preparing for the M. B. Examination for the University of London: Either *Fagge's Principles and Practice of Medicine*, or *Oiler's Principles and Practice of Medicine*, *Brisham's Art of Surgery*, *Green's Pathology*, edited by Montague Murray, and *Sims Woodhead's Practical Pathology*, *Galabin's Midwifery*, and *Lawson's Diseases of Women*. The special subjects are dealt with in these text-books sufficiently for the purposes of the examination. We would advise *Greig Smith's Abdominal Surgery*, edited by J. Swain, *W. H. A. Jacobson's Operations of Surgery*, *Shin Diseases*, by Malcolm Morris, *Tropical Diseases*, by A. Davidson, and *A Practical Treatise on Urinary and Renal Diseases*, by Sir William Roberts.

BOOKS OF D.P.H. EXAMINATION.

The books most generally read by candidates for the Diploma in Public Health of Cambridge University are *Whitelegge's Manual of Hygiene*, *Wilson's Hand-book of Hygiene*, *Wynter Blyth's Manual of Public Health*, *Louis Parkes's Hygiene and Public Health*, *Notter and Firth's Theory and Practice of Hygiene*, *Wanklyn's Water Analysis*; *Smith's Laboratory Text-book of Public Health*, *Kenwood's Public Health Laboratory Work*, *Balfour Stewart's Elementary Physics*, *Muir and Ritchie's Manual of Bacteriology*, *Crookshank's Manual of Bacteriology*, *Corfield's Dwelling Houses*, *McVail's Vaccination Indicated*, *Newsholme's Vital Statistics*, *Statton's Public Health Acts*, *Knight's Annotated Model Bylaws*, *Stevenson's and Murphy's Treatise on Hygiene and Public Health*, 3 vols., for reference on special subjects.

AN INDIAN SCANDAL.

THE home papers contain the announcement of the death at Colcutta, Hadlington, of Lady SUSAN GEORGINA BROWN, a daughter of the Marquis of Dalhousie, the Governor-General of India. Lady SUSAN BROWN divorced Lord Connaught while he was Governor of Madras; and latterly married Surgeon-Lieutenant-Colonel BRIGGS, who before the marriage, had assumed the surname of BROWN.

SHORT ITEMS.

Says the *Latent*:—"A brief paper in the *Indian Magazine* for January by Mr. Alexander Rogers recalls the fact "that the plague now raging at Bombay and other parts of the Presidency is precisely similar to one that prevailed about 250 years ago at Agra and in the North-West." He quotes an extract from a translation of the Emperor Jehangir's autobiography which he has now in hand, and were the names of persons and places altered we could easily fancy that we were reading an account of the present visitation."

His Highness Sir Bhagvat Singhjee, G.C.I.E., M.D., F.R.C.P., LL.D., Vice-President of the Indian Medical Association writes as follows to the Secretary of the Association:—"I have read with considerable interest the proceedings of the Indian Medical Association published in the *Record*. It is gratifying to note that the Association continues to increase its sphere of usefulness. Its success is entirely due to its able and energetic Secretary and to the Council."

Surgeon-Lieutenant Henry A. O. Dickson, F.R.C.S., L.R.C.P., Bengal Establishment, died at Sandgate on 27th January, aged 27. He was the third son of the late Rev. George O. W. Dickson, M.A., Vicar of King's Someborne, Hants, and entered the service as Surgeon-Lieutenant, 29th July, 1876.

Furlough for Indian medical officers is still closed, but no severe has been the strain of the past season upon the service that a good many doctors are being invalided. Calcutta in particular will see several changes in the next few months, as Brigade-Surgeon Lieutenant-Colonel Crombie is retiring while Brigade-Surgeon Lieutenant-Colonel O'Brien and Surgeon-Major Leahy have been ordered home on sick certificates. Surgeon-Major B. H. Charles, who is shortly due back from furlough, will probably act for Dr. O'Brien.

The Court-Martial held in Bombay on Assistant Surgeon David Davis, Indian Medical Department, on a charge of neglect to the prejudice of good order and military discipline, in that he was ordered by Surgeon-Major Drury not to leave his patient, Colonel Strachan, without permission, neglected to obey the order, was found guilty and sentenced to be reduced in rank. The sentence has been confirmed by General Nairne.

Since the Tirah Expedition commenced, no fewer than 1,756 soldiers, sick and wounded, passed through the British field hospital at Khushalgurh. In one week alone 75 wounded arrived from Kohat and were sent on to Rawal Pindi. The native field hospital has treated 1,400 epepyes and over 1,700 followers who were either wounded or invalided through fever or dysentery. Sick convoys pass on the sick and wounded, except those cases too serious to be moved.

Dr. Gangulin, B.S.C., M.D., of Dinapore, has lodged a petition of complaint against Dr. P. C. Mazumdar, Editor, *Indian Homeopathic Review*, the publisher of the journal, and Mr. D. N. Bannerjee for having published a defamatory article headed "Beware of American Colleagues" reflecting upon the character and reputation of the complainant. Summonses have been issued against all the three accused.

The death is announced at Chicago of Dr. Mark B. Lackrsten, late of Calcutta, who was a leading figure in the Indian Mutiny and a highly respected member of an old European family. On retiring from British employ where he held a high position he accepted a Professorship in the Post-graduate Medical College, Chicago, and died in harness at the age of 62 years.

Among the candidates who have passed in Medicine and Forensic Medicine in the examination of the Society of Apothecaries of London in January last, we are very glad to see the name of Miss Grace Friend Pereira, formerly a student of the Calcutta Medical College and for several years a practising physician in Chittagong. We wish Miss Pereira all success in her career.

The two eyes really see two objects. If the two forefingers be held one at the distance of 1 ft., the other 2 ft. in front of the eyes, and the former be looked at, two phantoms of the latter will be observed, one on each side. If the latter finger be regarded, two phantoms of the nearer finger will be observed mounting guard, one on either side.

Do tell me Doctor, "Is there no way of finding out what is really the matter with me?" queried a lady patient. "Only a post-mortem examination can reveal the truth," replied the doctor. "Then for pity's sake" cried she, do make it at once. I do not see why I should be at all squeamish at such a time as this."

Amoy, especially profuse and common at home, where 50,000 are consumed (i.e. grown) here or there in Amoy, while Hong Kong imports nearly 300,000 cases of patients from Africa and India, and of this quantity 150,000 cases are exported to 2,000 tons for conversion into "olive" oil for the Indian and South American markets.

English now boasts its lady dispensaries. The first lady who broke the ice of prejudice against female dispensaries in the land of William Tell was Fanny Lett, the daughter of a Karubamm Apotheker, who passed her examination "with distinction," and following suit the other ladies have passed equally high.

Dr. Frost writes a prescription for a Mr. Winter, of San Francisco, who sent it to Mr. Winter's drug store to be dispensed. Dr. Taylor of the S. F. and P. D. wants to know whether two Winters and Frost should not have caused a cold day or at least made the prescription chilly.

Dr. Lustig, we hear, has written to say that Dr. Gallotti will arrive in Bombay in the first week of March with a supply of the curative serum that proved so effective when applied by Dr. Lustig some months ago to patients in Arthur Road Hospital.

Miss Columbia Rivera, M.D., who has been given medical charge of the women's ward of San Andre's Hospital, can claim to be the pioneer woman Interner in Mexico, and Dr. Emma Wakefield, the first colored woman (i.e. negress) to earn a medical diploma in the United States of America.

The following are some Chinese medical maxims:—The physician who is sure of his diagnosis says little; he who is not sure talks much without being understood. "The greatest enemy to the health of man is woman; the worst enemy to the health of woman is man."

Surgeon-Lieutenant-Colonel G. S. A. Ranking, M.D., Secretary to the Board of Examiners, goes on tour on the 1st March. He will examine at Lucknow on the 3rd, 4th, and 5th March, at Meerut on 8th and 9th, returning to Calcutta on 12th sitting.

Glass, prepared by a new patented process, which renders it soft and malleable, is now used by dentists to fill the cavities in teeth. It is said to answer the purpose admirably and is less conspicuous than gold.

In the State of Pennsylvania all medical colleges are required to give a bond of \$100 as a guarantee that no human bodies will be dissected except those which come to them through the regularly appointed legal channels.

"I want some pills, please sir," asked a little girl of a certain druggist, who being a man of few words and wanting to know what pills she wanted, asked: "Anti-bilious?" and was met with the response "Oh, no Sir, Uncle's pills."

Regulations for the electric lighting of Calcutta are contained in the current Calcutta Gazette. They include provisions for securing the safety of the public, and for ensuring a proper and sufficient supply of electrical energy.

The practice mentioned in the above article is entirely new to the effect that the patient is not allowed to pay for his independent or semi-independent treatment, but he is charged as an ordinary patient, although the treatment is special.

The fact of his son being a practitioner does not entitle him to gratuitous attendance. He should be charged according to his true position in life and ability to pay.

The Hon'ble Nawab Syed Amom Hossain, M.A., Presidency Magistrate, Calcutta, is appointed *substantively* *pro tempore* to be Governor of Calcutta, *viz.* Dr. S. W. Chambers about to retire.

Brigade-Surgeon Lieutenant-Colonel D. D. Cunningham, Professor of Physiology, Calcutta Medical College, has been granted an extension of furlough up to the 25th of June next.

The official announcement of the baronetcy conferred upon Sir Samuel Wiles M.D., last June was made in the *London Gazette* of 4th February.

Miss H. McDougall, an English nursing sister, has lately died from plague. She contracted it by a patient coughing in her face, some sputum entering her eye.

Dr. Weir, the Bombay Health Officer, sustained a somewhat serious hurt through slipping in the verandah of the Municipal Office.

Dr. George Watt, C.I.E., Reporter on Economic Products to the Government of India, proceeds on furlough for eight months from May next.

Dr. Leathie, the late Agricultural Chemist to the Government of India, will shortly return to a similar post under the Government of the N.W. P. and Oadh.

Among the gentlemen upon whom the honor of knighthood was conferred by the Queen at Osborne, on 25th January, were Dr. Batty Tuke and Dr. John Struthers.

Surgeon-Captain W. Selby, of the 1 and 2nd Gurkhas, has been recommended for the Victoria Cross for his gallantry displayed in action on the Frontier.

Philadelphia contemplates giving fire-brigade officers a course in chemistry to enable them to successfully battle against chemical conflagrations.

A supply of Dr. Haffkine's prophylactic lymph has been received in Calcutta, sufficient for 5,000 inoculations, and more has been ordered for.

The *Colombo Globe* issues a caution that imported sandalwood oil "made in Germany" is nearly as well as cheap, being largely adulterated.

Madame Hu King Eng, who graduated from Pennsylvania Medical College, is chief physician in the household of the Chinese potentate Li Heng Chang.

The latest rumour has it that Dr. Murray, of Hongkong, will not see Dr. O'Brien when the latter goes on leave in April. We hope the rumour is incorrect.

We very much regret to announce the death of Jagabandu Bose, one of the few M.B.s. of the Calcutta University, on Monday, the 21st February, from multiple pneumonia.

Original Medical Literature

Tetany in Childhood

REPORTS the development a number of cases of tetany, spasms of the glottis, and other diseases accompanied by spasm. In the cases of tetany with spasm of the extremities, the disease closely resembled that of the adult. Spasm of the glottis occurred in all the cases; but was not necessarily severe or frequent. Fits were only once completely absent. As regards Mair's symptom, the author agrees that the increased galvanic irritability is the most constant and important symptom of tetany. TROUSSEAU'S phenomenon was not absent in any case. It persisted longer than the spontaneous spasm. This sign may be absent, but when present it is pathognomonic. ORTOGA's symptom was marked in all cases except one, where it was seen only in slight degree. The author says that this symptom is not pathognomonic, and may be present in other children, but in its most pronounced form it is only present in tetany. Muscular irritability was increased in all but one case. The knee-jerks were mostly exaggerated. Most of the children were excitable, but the intelligence was unimpaired except in one case, where there was a slight degree of idiocy. A rise of temperature was only once noted. In only one case of genuine tetany was the child well nourished. Rickets was generally present. There appeared to be a connection between the appearance of gastro-intestinal symptoms and that of the tetany. Hence the resemblance between infantile tetany and the tetany in gastric dilatation of the adult. The author accepts the view that there may be tetany without spasm of the extremities. In such cases EBB'S and TROUSSEAU'S phenomena are present. Such cases he puts down as latent tetany. Spasm of the glottis has nothing to do with tetany. As far as our present knowledge goes, treatment can only be radical where more or less marked digestive symptoms are present. A rapid emptying of the alimentary canal is here indicated.—*Brit. Med. Jour.*

Relation between Diabetes and Cirrhosis of the Liver.

AFTER referring to a number of previously-recorded cases of diabetes associated with cirrhosis of the liver, FUERNELLI reports an additional case of this somewhat rare combination. The patient was a man aged forty-eight at the time when the case was reported. His previous health had been good. In 1887, he suffered from jaundice for six to eight weeks. In 1888, he first noticed thirst, and $1\frac{1}{2}$ to 2 per cent. of sugar was found in the urine. After a visit to Darlebad, the sugar disappeared from the urine for some months, but then returned. In 1893, after a severe fright, ascites and jaundice developed, and at a later date oedema of the legs. Great enlargement of the liver and spleen was detected. The abdomen was punctured and ten litres of fluid withdrawn. On three subsequent occasions the abdomen was punctured, and after the fourth tapping, blood oozed from the punctured wound for some time. After the closure of the puncture opening, the ascites did not re-appear. The patient improved and returned to his business; the jaundice gradually disappeared and the liver diminished in size.

The point of greatest interest was the sugar excretion. During the year 1888, the amount of sugar in the urine was 3 to 5 per cent., but during that time the ascites was well marked, the sugar disappeared entirely. After the last paracentesis the glycosuria returned.

In a postscript, the author adds the termination of the case. After the patient had remained well for two and a

half years, the dropsy returned, the glycosuria diminished, death occurred, and the autopsy revealed typical cirrhosis of the liver.

The cause of the liver cirrhosis was not clear; there was no history whatsoever of syphilis or alcoholism.

The Nose as an Index of Disease.

INCOMPLETE signs of the eye indicating disease is usually an indication of disease of a severe type, either acute or chronic. This symptom is sometimes present in sleep which is unusual in consequence of pain. An unusual degree of movement of the nostrils in breathing indicates disease of the lungs or air-passages.

A contracted brow is indicative of pain in the head. Constriction or sharpness of the nostrils indicates pain in the chest. A drawn upper lip is indicative of pain in the abdomen. Brain affections are indicated by a contraction of the upper third of the face, chest diseases, of the middle third; and diseases of the abdomen, of the lower third.

What is known as "the Hippocratic countenance" is the precursor of death. Pallor of the face, if the tongue is also pale, indicates poverty of blood or fainting. Congestion of the vessels of the tip of the nose or the cheeks suggests obstruction of the portal circulation or a tendency to degeneration of the arteries.

A puffiness about the eyes is suggestive of Bright's disease. A bronzed appearance of the skin is a symptom of Addison's disease. Undue prominence of the eyes indicates exophthalmic goiter. A small pupil which does not contract on exposure to the light is a nervous symptom of locomotor ataxia.

Palpitation of the Heart.

HUGHARD for purposes of treatment divides cases of palpitation of the heart into those varieties which are, and those which are not, benefited by cardiac stimulants. Those cases arising from the ingestion of poisons, coffee, tobacco, and drugs, such as sulphate of quinin, are usually relieved by a removal of the cause. Palpitation due to gastro-intestinal disturbance, usually occurs at night, and is associated with dyspepsia and hyperacidity. For the most part these attacks may be cured by large doses of alkalies, and regulation of the diet. Iron, if taken in too large quantities, may also produce palpitation.

There is no necessary connection between cardiac palpitation and cardiac disease. The disease usually accompanied by palpitation, and which are improved by digitalis and similar remedies are beginning aortitis, acute endocarditis and pericarditis, adhesions of the pericardium, and mitral insufficiency. In such cases the following prescription will often be found useful.

R Quinine hydrobrom gr. ix
Digitalis gr. xxx
Ext. convallaris gr. xxx

M. Ft. pill. No. xl. Sig. Two to four pills daily.—*Med. News.*

Clonic Movements in Syringomyelia of Medullary Origin

HAVE been attributed to the motor area of the brain and sometimes appear as if a partial epileptic attack of cortical origin; but MARXWICK's researches show the convulsive attacks result solely from the medullary irritation, independent of any cortical interposition.

Pulmonary Phenomena of Hysteria Origin.

M. LEONI describes a puzzling case where fever rises and other symptoms of pulmonary tuberculosis changed their position daily from right to left side and sometimes altogether absent. Electricity aided by suggestion and moral persuasion effected rapid and complete recovery.—*Jour. Amer. Med. Assoc.*

SURGERY.

Significance of Pain.

AMQUIST on the general law of the cutaneous sensory nerves being always in association with the vascular nerves of the underlying parts, W. H. THOMSON points out that in diagnostic value alone pain cannot be surpassed by any of the common signs of disease; but as pain differs much in kind, and in character, and verbal descriptions of pain may be extremely indefinite, he regrets that too little regard is shown to the clinical value of the gestures a patient uses while describing his pain, and which gestures, as a rule, are characteristic enough to afford truer indications towards a right beginning in diagnosis than is possible for his language to convey. He quotes a number of examples indicating the necessity for distinguishing by voluntary or involuntary gestures the special varieties of pain which he classifies under six heads:—(1) Inflammatory pain for which opium is the best drug and next to which is acouite, especially in serous membranes and cardiac inflammations, but the coal-tar analgesics are useless in inflammatory pains, but there is a voluntary as well as involuntary tendency to keep the inflamed part at rest as much as possible. (2) Pains due to pressure, as by tumours, abscesses, &c. shown by repeating the movement in a contrary direction (3) Stretching pains as in colic or cramps, where the patient forcibly grasps his abdomen (4). Neuralgic pains where relief is sought by friction or pressure. (5) Subjective pains, as in hysteria, where gestures and language are more of relating a woeful past than of a present reality. (6) Cutaneous reflex pains in which, as a rule, the hand 'hovers' over the affected part.—*Med. News.*

Intestinal Obstruction preceded by Passage of Air and Fæces in the Urine for Fourteen Years.

J. C. CLARKE tells of a man set 47, who had mild cystitis for 14 years and bladder irritability accompanied by sputtering and explosive discharges of air during micturition. In 1885 he had a short attack of bilious vertigo, after which the bladder trouble got worse, and in 1886 retro-vesical fistula was diagnosed, while debris of muscular and vegetable tissues were found in his urine. His symptoms fluctuated—improving and getting worse—till March 1893, when after a severe cystitis faecal matter passing freely into the bladder was without difficulty discharged per urethram, but no urine passed per rectum, and though habitually constipated, bowels acted twice daily till August, when they refused to act, and four days later his abdomen becoming painfully distended, was not reduced by saline purges or enemata. As symptoms were becoming urgent and there was no relief to the distension or obstruction, by the 24th idem Dr. CLARKE, in conjunction with Drs. D. LEBON and F. A. SOUTHAN, opened the coccum by means of right inguinal colotomy and thus relieved the obstruction which, they believed, existed somewhere in the large intestine. The man made a rapid recovery.—*Lancet.*

Ideal Catgut Sterilization.

EVER since LISTER'S discovery of catgut, the advantages of aseptic animal ligatures became more and more recognised, but the difficulty lay in rendering the material sterile and mildly antiseptic without impairing its tensile strength. LISTER'S method of making catgut aseptic was too crude and gave way to other modes KOCHER abandoned his juniper catgut. Carbollised, sublimated and chromicized catgut not infrequently causes wound infection by imperfect sterilization, and even dry sterilization cannot be relied on as absolutely safe for practical use, since LANNSTEDT proved that none of the present methods of disinfection can render the field of

operation absolutely aseptic, and EWALD furnished positive proof that sterile catgut still contains bacteria that retard repair by promoting aseptic supuration. Formation so alters the texture of gut or leather as to increase rather than impair its tensile strength by repeated boiling, and HOFMEISTER came nearest the mark for an ideal catgut mixture, but for the corrosive sublimate acting as an irritant. H. SARR, (*Jour. Amer. Med. Assoc.*) therefore modifies the HOFMEISTER process by (1) tightly winding the catgut in single layers on glass drainage tubes, (2) which is then immersed for 12 to 48 hours in a 2 to 4 per cent. aqueous solution of formalin, (3) after acting on the catgut by immersion in formalin for 12 hours in flowing water he (4) boils it for 10 to 30 minutes in water and then (5) hardens and preserves it by keeping it in glass stoppered bottles containing a mixture of absolute alcohol 950, glycerine 50 and iodoform 100 parts, and claims that if this catgut does not destroy pus microbes it inhibits their growth and accelerates repair.

Anæsthetic Statistics.

PROFESSOR GUNT of Berlin presents the returns furnished during the two preceding years as follows:—

During 1895—96 there were 29,596 administrations.
" 1896—97 " 29,178 "

Of these, chloroform was employed in 87,401 cases, with

			29 deaths.
"	ether	18,856	" 8 "
"	Billroth's mixture	996	" no "
"	chloroform and ether	4,927	" no "
"	bromether	1,489	" no "

The mortality may be otherwise stated as—

For chloroform, 1 death in 2,039 cases.

" ether, 1 " 5,090 "

In the reports for different years the mortality from chloroform has varied from one death in 1,100 to one death in 4,200, and from ether, from one in 2,800 to one in 5,700. In the first three years there was no death from ether reported. The total statistics now include 327,593 cases, with 134 deaths, or one death in 2,444 administrations.—*Edin. Med. Jour.*

Renal Surgery.

ALBARRAN strongly advocates catheterism of the ureter for the cure of hydronephrosis; and, if that be inefficient, failing to empty the kidney, the catheter should be left in and the organ explored by operation. By means of the instrument, the seat and nature of the obstruction may be ascertained, and then uretero-pyeloctomy can be performed with relative ease. Nephrectomy should never be the first step in pyelonephrosis. As a rule, the general health of the patient and the condition of the opposite kidney contra-indicate this operation, and nephrotomy is the right course. Should it be found advisable later, when health is restored, to remove the kidney, secondary nephrectomy can be done under better conditions. A retained ureteral catheter will greatly shorten the duration of a nephrotomy fistula; and ALBARRAN treats a spontaneous fistula in the same way. He greatly distrusts nephrectomy for malignant tumours as recurrence is the rule. Partial nephrectomy for adenomata seems to mean the hastening of recurrence; indeed, these growths are of a nature which perhaps justifies total extirpation of the organ. On the other hand, ALBARRAN finds that in unilateral tuberculous disease it is best to remove the kidney as soon as possible. Nephrotomy is merely palliative in renal tuberculosis, counteracting retention when the patient is too ill for operation, and above all when the disease is bilateral. In nephrorrhaphy it is not only useless but dangerous to dissect off a portion of the capsule. The process prolongs and complicates the operation and increases the local sclerosis of the kidney.—*Brit. Med. Jour.*

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.

Physiology and Therapeutics of the Thyroid Gland and its Outgrowths.

Describes that thyroid extract, which should not be given in quantity sufficient to produce symptoms and is specific in myxedema and cretinism and has given good results in simple goitre, obesity, scleroderma and tetany, though it is contraindicated in albuminuria, glycosuria, heart lesions and nephritic goitre and is of doubtful value in psoriasis and other skin diseases, insanity, tuberculosis, rickets, etc. H. GIDSON WELLS explains that admitting of great hypertrophy with a slight degree of regeneration and reaching its highest development at adult life, the thyroid gland discharges by the lymphatics into the general blood current a colloid material containing the active principle, thyrotoxin which contains 10 per cent. of iodine and not only acts as an antitoxin to the poisons causing auto-intoxication or produces some substance necessary to tissue metabolism, but is also necessary to the animal economy, since absence of it induces myxedema in adults and cretinism in children, and the amount of iodine in the thyroid glands of the people of any given place varies inversely with the prevalence of goitre in that district.—*Med. & Surg. Rep.*

Healthfulness of Laughter.

AN English scientist, Dr. R. CAMPBELL, has written an essay dealing with the physiologic effect of laughter. When we laugh, he says, we increase the play of the tension of the lungs, and that one result of this increased tension is to arrest the blood-flow in the lungs and thus induce the taking of deep inspirations. These latter are health processes, for many parts of the lung are not called into active use during ordinary breathing. Hence, laughter is an exercise and a good one.—*Med. News.*

Solubility of Gallstones in Oil.

TAKING some friable dark-greenish brown faceted gallstone, that had been passed by a patient under the olive oil treatment, SCOTT exposed them at 98.4°F in vessels containing olive oil, almond oil and paraffin respectively and found that after 24 hours immersion little was left but the nuclei of the stones which dissolved with almost equal readings in the different oils, approximately losing 0.25, 0.5 and 0.75 of their weight respectively in 12, 24 and 48 hours and dissolving in regular layers. For the second experiment the stones were removed from the gall bladder by operation, but though they dissolved uniformly they maintain their hardness and brownish-yellow color and exhibited no well-defined layers. They seemed to contain more pigment and salts than the other stones and lost much less weight during corresponding periods of immersion. After 4 days those in olive oil lost a little more than half, those in almond oil exactly half, and those in paraffin less than one-third of their original weight. In the third series the stones were obtained by operation and were as large as filberts. They commenced to dissolve in one hour, but the percentage loss of weight was relatively less than in the second experiment, and at the end of 25 days those in olive oil lost little more than half, and those in paraffin rather more than one quarter of their original weight.—*Brit. Med. Jour.*

Frontal Injection.

EDWARD P. DAVIS describes cases of hemorrhage from various mucous surfaces and of great stools in the newborn infant, and has specially investigated their bacteriological complications. These cases he ascribes to prenatal infection. In the faeces were found the bacillus coli communis,

the micrococci pyogenes aërius, and the micrococci pyogenes albus. The treatment adopted was copious subcutaneous irrigation with normal saline solution, and this was successful in all cases. A cocoon was obtained from the head of infants with the grave form, which, when injected into the bodies of pregnant guinea-pigs, was found in the young pigs. It most closely resembles the micrococci associated with yellow fever. The condition is a toxæmia of apparently intestinal origin; but whether the germ gives entrance to the foetus by the placenta or by the umbilical vessels during birth is uncertain.—*Brit. Med. Jour.*

Toxic Effect of Infinitesimal Quantities of Metallic Salts on Living Organisms.

RAULIN astonished the world by showing that *Aspergillus Niger* would not live in water placed in a perfectly clean silver vessel, and that its growth was inhibited by 1 part silver nitrate in 1,000,000 parts of water, but the results of CARL VON NIEBEL's studies on aplogrya were simply stupefying. He found that if placed in a solution of 1 part silver nitrate in 1,000,000,000,000,000 parts of distilled water for 3 or 4 minutes, these organisms died in a different manner to what they did when placed in comparatively strong solutions of this salt. In the latter instance death was due to chemical action, the cellular contents disappearing from the membrane, the bands of chlorophyll changed color but not position, and the cell lost its turgescence. With infinitely diluted solutions death was due to oligodynamia in which the cells maintain their turgescence, the chlorophyll spirals agglomerate, become shorter and separate from the plasma which remains in place. Corrosive sublimate gave more startling results, as a solution of 1 in 1,000,000,000,000,000,000,000,000 killed the organism. He found that many substances supposed to be insoluble in water, such as metallic gold, mercury, &c. if merely placed in the water impart to it this oligodynamia virtue which could however be destroyed by adding flour, cellulose, wood, &c. to the water, and toxic water also became neutral if a sufficient number of organisms were placed in it.—*International Brief.*

Directions for Preparing Specimens of Blood.

THE skin covering the tip of the finger is thoroughly cleansed and then pricked with a clean needle deeply enough to cause several drops of blood to exude. Two large drops are then placed on the glass slide, one near either end, and allowed to dry without being spread out on the surface of the slide. After they have dried, the slide is placed in the holder and returned in the addressed envelope to a culture station, or mailed to the laboratory. The blank giving the history of the case must be filled out in full and forwarded with each specimen. The data thus obtained are for record.

Nasal Micro-organisms.

IN all bacteriologic investigations of the nasal fossa, in all researches as to the action of nasal mucus, etc., a clear distinction must be made between the vestibule of the nose and the proper mucous cavity. The former is lined with skin, and is not part of the nasal cavity proper, but only leads to it.

Contamination with the flora of the vestibule is difficult to avoid, even when this source of error has been realized: In the dust and crusts of mucus and debris deposited among the vibrissae of healthy subjects, micro-organisms are never absent, and are usually abundant.

On the Schneiderian membrane the reverse is the case; under normal conditions micro-organisms are never plentiful here, are rarely even numerous, and in more than eighty per cent. of cases no organisms whatever are found and the mucus is completely sterile.

The occurrence of pathogenic organisms must be so infrequent that their presence on the Schneiderian membrane can be regarded only as quite exceptional.—*Med. Age.*

Correspondence.

CIVIL MEDICAL APPOINTMENTS AND THE WAR RESERVE.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—*Après* of the above, about which letters have appeared in the *Indian Medical Record*, I have to make a few observations. In a recent issue of yours, a correspondent published names of Military Assistant Surgeons with English qualifications. With what view it is hard to say. If it was intended to hold them up to ridicule, and show that, in spite of degrees and diplomas, they are still and always liable to be relegated to compounding work, and to go round the wards with hand-books, the effort was a marked success. I will be more explicit: among the M. A. S. of the Bengal Presidency, there are four men holding diplomas from the Colleges of Physicians and Surgeons, Great Britain and Ireland. On the call for military duty, only one man held on to his civil work, the other three were sent away at a moment's notice, in plain language, for subordinate and compounding work. I was always under the impression that a diploma conferred on the holder certain legal rights and status in all countries under the English flag, which as far as I know, were never challenged or set aside. Yet in the I. S. M. D., we see qualified doctors placed under inferiorly qualified assistants. I do not mean any offence to the latter class, but contrasted with those who have qualified in England, the comparison holds good. Will any one, who has ideas of right and wrong, glance over the Army List for the last quarter. The whole of the war reserve was not called out, as there are still about 20 M. A. S. on the civil list. The question arises; How is this picking, choosing and sorting done? I do not at all mean to say that qualified men should not be removed from civil work on the call for military duty, but certainly when non-qualified men are available, the former should not be disturbed in their preferable claims. I am sure every right-thinking person will agree, that professional rights should be rigidly guarded. Only the other day there was a storm in a tea-cup, when a young Eurasian lady, who had had a local training, was entertained as a temporary nurse, and posted to one of the Base Hospitals for duty, at once there was a hue and cry, and a para appeared in *Truth* dilating on the enormity of the offence. Needless to say it had effect. So that nurses can gain their rights, because they have all powerful aid to back them up, but qualified men none. May I ask if a Surgeon-Lieutenant A. or I. M. S. would serve under a Surgeon-Major I. S. M. D.? I trow not, although both bear commissions from Her Majesty. From a professional point of view, it would be, to say the least of it, unjust. The position of a qualified man in the I. S. M. D. in military duty is an anomalous and hard one indeed. Medical officers look on him with disfavor, he is made to feel his position keenly, there is no shadow even of extending professional courtesy to him and his legal status is ignored. With other M. A. S. he fares worse for there are jibes and petty insults. "His Degrees and Diplomas are worth nothing, there are other men without these adjuncts in civil work." At present there are three qualified men in military employ, with salaries ranging

from Rs. 110 to 160 per mensem! Just think of it, what rewards wherewith to compensate men for their energy and professional attainments.

Some time ago, it was rumoured that one or two Commissions in the I. M. S. would be given annually to qualified M. A. S. as is done in the rank and file of the army, but nothing has come of it yet. Later on, it was suggested, that on gaining diplomas, the honorary rank of Surgeon-Lieutenant would be bestowed—both points have been ignored, and a retrograde movement seems to have set in. There are a good few now in civil employ, who have gained their posts, not through professional merit, but that they had clerical influence at Head-Quarters. In my opinion the better class of civil billets should be given, firstly, to qualified men, and then to those who have passed well from the local medical colleges. It is to be hoped that the present officiating Director-General, I. M. S. one of the foremost medical officers in his profession, will do an act of justice to those of his fellow professionals in the I. S. M. D., who have been working away uncomplainingly for months in military employ, and have them suitably rewarded with civil posts.

Yours &c., ORLOOKER.

(There is considerable justice in these claims and we would respectfully invite the kind attention of the Director-General, I.M.S. to the matter.—ED, I.M.S.)

—:—

HIGHLY PLACED ANGLO-INDIANS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—As you have expressed a wish to receive the names of Anglo-Indians and Eurasians who have risen to good positions in the Government service or have otherwise rendered valuable services to the State, I have the pleasure of sending you a few names from the Bombay Presidency which I do not find have been communicated to you before. The idea of collecting such names with a view to bring them before the public, it is needless to say, is an excellent one and meets with general approval, and I only hope that in a very short time you will have a good array of names, of which we, as a class, may well be proud. To begin, I would mention:—

1. Major Lionel A. Thomas McCudden, 7th Foot, 8th Bombay Native Infantry. Date of 1st Commission, 16th March 1867. Date of Admission to Staff Corps, 30th November 1870. Major Wing Commander 8 Bo. N. 1st February 1889. 2nd in Command, Staff Employment, 1893. War services; Afghan War, 1880; march from Quetta to relief of Kandahar, Medal; Burmese Expedition, 1885-1887, Medal with clasp. This gentleman has retired from the service, and the above can be verified from the Bombay Army List, 1890.

2. Frederick Hutchinson, Assistant Secretary to Government, Revenue Department, Bombay, who subsequently had the unique honor of being the first Unconvenanted Officer who held the appointment of Collector of Bombay, now reserved for the Civil Service.

3. Edward Pratt, Assistant Secretary to Government, Judicial and General Departments, Bombay, and in his time one of the principal Municipal Commissioners of Bombay.

4. Edwin Freeborne, Actuary, Government Savings Bank, Bombay.

1. *James Lawrence, Assistant Secretary to Government, Revenue Department, Bombay.*

2. *A. R. King, Assistant Secretary to Government, Bombay.*

3. *William Meldmont, Assistant Secretary to Government, Bombay.*

4. *Salomon Wright, State Auditor, Bombay.*

5. *Henry Frederick Brayson, Senior Deputy Collector, Madras Commission.*

10. *Isaac Dronow, Deputy Collector, Dharwar.*

11. *John Christian Anding, Deputy Collector, Belgam.*

12. *John Cornelius Whitcombe, Superintendent, Revenue Survey, Poona.*

I could add considerably to the above list, but I fear I have already trespassed too much on your space.

Yours &c., W. H. T.

KARACHI, 18th February 1898.

(We will gladly publish ALL the names. Send them in.—ED., I.M.R.)

INCREASED MORTALITY FROM FEVERS IN MADRAS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—In your leader of 1st February 1898, you prove that a high fever mortality prevailed with a low sub-soil water and *vice versa*.

In your impartial criticism, to speak according to the actual facts observed by an unscientific and humble pupil of Dr. KING, almost all must admit that you have come nearer the mark than he has.

One proof of this was the almost completely dried up state of the silvery Cooum River, the chief drain and receptacle of Madras filth, during the great prevalence of fever and high mortality.

Between 1878 and 1892 it was invariably observed in both the General and Station Hospitals on the bank of the Cooum River, that when the river was very low, and unflushed by the sea (owing to the silting up of the bar) it emitted an unbearable stench into the hospitals, the fort, and the town.

This caused the inhalation of the quintessence of filth, and the breeding of unlimited swarms of mosquitos, which sticking to the white walls of hospitals and other buildings made them look almost black.

These, combined with extreme heat, banished rest at night, and were enough to drive people mad.

The remedy proposed was to keep the bar always open, to flush the Cooum, and prevent the drains opening into the river; but the expert, Mr. COOMES, could only suggest a drainage scheme of a very costly nature. The difficulty being to drain a place that is apparently lower than the sea.

It is a common saying that the Cooum mosquito inoculate organic poison into the human system, predisposed to disease by its environment. Imagine our distressful difficulties in Madras, a climate without rain and with grilling heat, and a low sub-soil water polluted with the fermenting organic poisons of a city added to which we have an excess of cyanic acid and sulphuretted hydrogen arising from the soil and drains, etc., and that moisture from the sea close by. Could insanitation be worse?

It will be remembered that the late Lord HUNTER, Governor of Madras, died in 1878 when the Cooum was low.

Yours &c., SUSANNA.

THE TREATMENT OF DYSMENORRHOEA.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Will some one oblige me and my patients with apt suggestions for treatment curative or at least palliative. Both the cases are chronic of about 10 years standing. There is no reliable consultant available in the neighbourhood, hence this request.

I. A virgin, about 23 years old, excruciating pain for the first three days of each period, cervix in hollow of sacrum, fundus felt in front of cervix, sound only goes at most for about one inch, movement of uterus causes a dragging pain in the right iliac region, ante flexion with adhesions. Anodynes used and Hewitt's cradle pessary worn for six months, failed to give relief.

II. A woman, about 24 years old, married for 9 years, no child, pain very severe for three days before and for the first three days of the period, fundus felt behind the cervix, the sound can be passed with some difficulty but its rotation to the normal position causes severe dragging pain. Leucorrhoea for a week after the period. Retroversion with adhesions.

Suggestions earnestly solicited.

Yours, &c., B. G. ALPA.

(Both these cases can be cured in six months by the use of a light silver intrauterine stem. Relief from all suffering is almost certain after six weeks wearing of the stem.—ED., I.M.R.)

MEDICAL ADVERTISING IN CALCUTTA.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—The annexed advertisement is cut out of the *Statesman* of the 25th February 1898, and it is appearing daily in that lay paper:—

NOTICE.

I have this day purchased the good-will, stock-in-trade, and outstandings of Messrs. HOWARD and Co., Chemists and Druggists, of 48, Dhurrumtollah, free of all encumbrances and liabilities.

The business will be continued, as before, under the personal supervision of Mr. J. E. DANIELS.

CONSULTATION DEPARTMENT.

Dr. ——— attends from 8 to 10 A.M. daily.

Dr. ——— M.D., attends from 10 to 11 A.M. daily, excepting Sundays.

Dr. ——— M.B., Edin., attends from 7 to 8 A.M. and 4 to 5 P.M. daily.

MASUD KHAN, Proprietor.

Mr. ——— is an Honorary Surgeon-Lieutenant I. S. M. D., Dr. ——— is L.R.C.P. & S. Edin.; Dr. ——— also holds a Scotch qualification.

From the advertisement it would appear that all these European gentlemen are employed by the native who is the proprietor of the chemist's shop in which their professional services are given.

Yours &c., SUSANNA.

(We have omitted the names of the gentlemen mentioned, and we trust they will see their way to sending this advertisement and important advertisement to be removed from the *Statesman* at once.—ED., I.M.R.)

ANGLO-INDIAN LADY DOCTORS.

To the Editor, "INDIAN MEDICAL RECORD."

Sir,—The following are a few ladies of the Anglo-Indian community of Bombay, who have done credit to their Indian training:—

1. Mrs. Frank Sharpe, née Wells, L.M.S., 2nd Physician, Cama Hospital, Bombay.
2. Miss Alice L. Mackenzie, L.M.S., Dufferin Hospital, Gt. Gt.
3. Mrs. Annie Gordon, nee Dunn, L.M.S., M.D., Medical Mission, Bangalore, C. P.
4. Miss Emmeline DeCunha, L.M.S., Plague Committee, Bombay.
5. Miss Mary Bernard, L.R.C.P. & S. Edin., State Hospital, Bhopal.
6. Miss Mildred Graham, L.R.C.P. & S., L.F.P. & S. Edin., in medical charge Oodyspore Hospital, Oodyspore.
7. Miss Helen Lauder, L.M.S., L.R.C.P. & S. Edin., L.F.P.S. & M.D., Brussels, Dufferin Hospital, Ulwar.
8. Miss Annie Brennan, L.R.C.P. & S. Edin., L.F.P.S., L.M. Dublin, on Plague inspection duty.
9. Miss Rose Ferreira, L.M.S., Bombay.

Yours &c., M. T. C.

(Will some kind friend be good enough to send us the names, qualifications and addresses of Anglo-Indian lady doctors in other Provinces—ED, I. M. R.)

BREVET COMMISSIONS.

To the Editor, "INDIAN MEDICAL RECORD."

Sir,—A "Sufferer" suggests that Assistant Surgeons employed as Civil Surgeons should hold the temporary rank of Surgeon-Lieutenant to enable them to draw the higher rate of travelling allowance. This, I think, is feasible, but the following taken from the Civil Service Regulations—our guide while in civil employ—suggests a precedent and principle which could be easily followed in the case of Assistant Surgeons while employed in a higher capacity.

1103 (c). A certain number of upper and lower subordinates, according to a scale to be sanctioned from time to time by the Government of India, P. W. D., placed in charge of districts of the Buildings and Roads Branch, N.-W. Provinces and Oudh; and upper subordinates according to a scale similarly sanctioned placed in charge of sub-divisions of the Irrigation Branch, Bengal, N.-W. Provinces and Oudh and the Punjab are allowed travelling allowance at the rates admissible to Assistant Engineers or Sub-Engineers, as may be ordered by the Local Government.

Yours &c., ANOTHER SUFFERER.

THE LEGITIMATE PREVENTION OF CONCEPTION.

To the Editor, "INDIAN MEDICAL RECORD"

Sir,—To start with, let me say I am one who does not believe in the indiscriminate prevention of conception, and I recognise no legal claim for this step, except that of the physical inability of the woman to bear a healthy full-term child. It is only to this class of cases that the prevention of conception is, I believe, morally and legally allowable.

The method I propose has never failed when carried out properly. I cause to be introduced a rubber cup over the neck of womb (the French pessary) just before intercourse. I explain how I want it to fit the neck of the womb. After intercourse, inject one quart of warm water into the vagina with a rubber syringe. Then remove the rubber cup, and inject one pint of warm salt water high up in the vagina; then have a small ball of absorbent cotton with string attached, saturated with iodo-glyceride, introduced high up in the vagina. Leave this cotton in eight or ten hours, then remove it. This method is certain and harmless.

Medical men, I think, ought to know of some definite way of preventing conception, and thus spare those unfortunate patients with deformed persons, from the dangers of an induced abortion.

Yours &c., OBSTETRICIAN.

ACTIVE SERVICE FOR SENIORS. A HARSHIP TO JUNIORS.

To the Editor, "INDIAN MEDICAL RECORD."

Sir,—Having heard that the Senior Assistant Surgeons about to retire, are to be kept on the active list, I wish to tell you that this will be a great hardship and injustice to us men who have been looking out for promotion for 34 years, and now find the way barred by fortunate fellows who got their commissions after 26 and 28 years' service, 6 and 8 years before us. It is very disheartening, and the loss in pension which it will cause will be a greater injustice than the lost pay. I beg you will take up the matter and ask Government to keep these senior men on as supernumerary to the fixed establishment, which would not then interfere with our legitimate advancement.

To have done hard work and patiently waited through long years of stagnation in promotion, and after 34 years' service to find the way barred by fortunate men is simply disheartening. If you will kindly help us, we shall be at all times grateful.

Yours &c., HOPE DEFERRED.

BABOOGAR, 12th February 1898.

(We understand the fears expressed in this letter are unfounded, and that no such steps are contemplated by Government. Were they adopted, as feared, we certainly think the additional active service should entail the incumbents being placed on the supernumerary list.—ED, I. M. R.)

EFFRONTERY AND INSULT TO A PHYSICIAN BY A NATIVE DISPENSARY.

To the Editor, "INDIAN MEDICAL RECORD."

Sir,—A native chemist's firm within a stone's throw from the Record office, had the impertinence and effrontery to insult a most reputable physician in this city the other day, by boldly advertising his name and qualifications on its hand-bills, backing them by a special puff of their own about his skill. These hand-bills were distributed broadcast over the streets of Calcutta, and attention was drawn to them. Finding that one of the medical practitioners (a retired Honorary Surgeon-Lieutenant) who was also being advertised on these hand-bills had his name, pedigree and puff of sorts, posted on the street frontage, we naturally concluded that he was fully aware of the hand-bill advertisements. The objectionable hand-bill was forwarded to the other physician (whose name, though on the hand-bill, was not to be seen on the street door.) His reply was: "I am in receipt of your kind note

drawing my attention to my name being used by Howard & Co., in their circulars or hand-bills. I am very thankful to you for it. I have already written to Howard & Co. on the subject, protesting against their conduct." The doctor in question is entitled to damages from the native proprietor of the chemist's shop for making such an unwarrantable and unprofessional use of his name on his hand-bills should be strongly advised. The Honorary Surgeon-Lieutenant, who figures on the same hand-bill, to cause such proceedings to be put a stop to or the question may arise whether a gentleman, holding the Queen's Commission, can permit his position to be compromised in this way.

Yours &c., M. I. M. A.

DO CARRION EATERS OF PLAGUE CORPSES SUFFER FROM PLAGUE.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Can you inform me through your journal whether birds of prey—vultures that feed on plague corpses in the Tower of Silence—ever get the plague and die, and if not, why not?

Also whether hyenas and jackals ever get cholera after feeding on cholera corpses? Have you ever heard of an epidemic of these diseases amongst these birds and animals.

Yours &c., JOHN E. WHITE,
Medical Officer, Godavari District.

KOVUR, 7th February 1898.

(We would like to find these queries answered if it be possible.—ED., I. M. A.)

Book Reviews.

THE ASEPTIC TREATMENT OF WOUNDS.

By DR. C. SCHIMMELBUSCH.

Translated from the German,

By A. THEODORE RAKE, M.B., B.S., Lond. F.R.C.S.,
Pathologist to the East London Hospital.

(Publisher: H. K. LEWIS, 136 Gower Street,
London, W. C. Price 5s.).

HAVING visited Professor Von Bergmann's University Clinic in Berlin a few months ago, and having seen the whole of the ingenious apparatus described in this work for the aseptic treatment of wounds, it is with much pleasure and interest and profit that we have carefully read Dr. Rake's translation of Dr. SCHIMMELBUSCH's little monograph on this vitally important subject; the author emphasises the importance of this method of treatment; he details the factors inducing infection by act and by contact with surrounding objects—the surgeon and his assistants included—and the material causes of wound infection are set forth with clearness. The *crux* of the book is "disinfection," and the bulk of the author's thoughts are occupied with this theme; the disinfection of the patients, the sterilisation of instruments, dressings, sutures, ligatures, sponges, drainage and irrigation appliances and the whole paraphernalia of the operation room from the surgeon, the patient, the assistants, the nurses, everything from the roof to the floor, are precisely and laboriously dwelt upon, since the quintessence of care and absolute cleanliness are the *sine qua non* of success in aseptic surgery. Unquestionably Dr. Rake has placed English surgeons under a debt of gratitude to him for his accurate and faithful translation of this valuable treatise by Dr. SCHIMMELBUSCH, which bears the impress of so great a surgeon as Professor VON BERGMANN, who was the teacher of the author. No practical surgeon can afford to lose the opportunity of learning the modern principles of wound treatment as taught in this volume.

MASTOID ABSCESSSES AND THEIR TREATMENT.

By PROFESSORS DUPON & LUSTIG-BARROW of Paris,

Translated from the French.

By HENRY J. CURTIS, M.D., B.S. Lond. F.R.C.S. Eng.

Assistant Professor of Pathology, University College,
London, and Assistant Surgeon, Ear and Throat Department, University College Hospital.

(Publisher: H. K. LEWIS, London. Price 6s.)

THIS memoir entitled "Les suppurations de l'Apophyse Mastoïde et leur traitement," was awarded the Prix Moynot by the French Academy of Medicine in 1894. From clinical, pathological, therapeutical and modern operative stand-points, this little brochure must be considered an embodiment of the clearest and best views on an intricate yet essentially practical and important surgical topic. It is illustrated with colored diagrams that portray with definite lucidity the anatomical description, and surgical relations of the mastoid region, and these with the graphic literary dissertation of the subject, make the comprehension of this difficult domain of surgery most intelligible to the student and the surgeon.

SURGICAL PATHOLOGY AND PRINCIPLES.

By J. JACKSON CLARKE, M.B. Lond. F.R.C.S. Eng.

Curator, and Pathologist to St. Mary's Hospital
Medical School, London, &c.

(Publishers: LONGMANS, GREEN & Co., 39 Paternoster
Row, London. Price 10s. 6d.).

Surgery and surgical pathology are both well taught at St. Mary's Hospital Medical School in Paddington, London. This book exemplifies the splendid basis of teaching upon sound pathology and well-studied principles of surgery, as they are expounded in the pathological museum and in the course of demonstrations carried out in that famous institution. As a trustworthy guide in Surgical Pathology, this little work of 440 pages has no rival.

THE "VOLUNTEER."

THIS is the title of a new weekly journal "devoted to the interests of volunteering in India." It is well edited and well got up, and judged by the pabulum offered in its first issue, we reckon that volunteers will find it both interesting and advantageous to rally round this organ of their craft. The whole question of volunteering needs ventilating, as both here and abroad the immense value of the unpaid military power of India is almost absolutely unknown, and where it is mentioned as an existing factor of strength to the Government, its intrinsic merits are very much under-rated and misunderstood. If our contemporary—to whom we heartily wish a long and prosperous career—will instantly publish an authorised census of the Anglo-Indian volunteer forces, and encourage the wider extension of volunteering, he will do an inestimable service to India and to the domiciled British community.

WELLCOME'S MEDICAL DIARY AND VISITING LIST.

THIS welcome annual visitor is fast becoming a most popular publication. It is a thoroughly well got up Diary and Visiting List which no physician can afford to be without unless he has provided himself with the old-fashioned and deservedly well established "LETTERS." Messrs. Burroughs, Wellcome & Co.'s MEDICAL DIARY is quite as good and as useful as LETTERS, but it comes out late and cannot therefore supersede LETTERS, which is usually in the hands of publishers in India by the month of November. This fact ought to be borne in mind if WELLCOME'S DIARY is to find a place in the daily life work of every physician in India.

GOVERNMENT OF INDIA.

Surgeon-Major Genl. J. Chapman, M.D., D.S.I., I. M. S., D.R.C.P., I. M. S. and Surg. Commandant with the Govt. of India, General Service, sent out of India for eight months.
Surgeon-Major Genl. R. Harvey, M.D., M.B., B.S., D.R.C.P., I. M. S., D.S.I., and Officer, Punjab District, to officiate as Dir. Genl. I. M. S. and Surg. Commandant with the Govt. of India.
Surgeon-Major R. Ross, I. M. S. (Madras), is placed on special duty under the Dir. Genl. I. M. S., from 17th Feb. 1898.

The services of Surg.-Capt. C. N. Bensley, I. M. S. (Bengal), are placed permanently at the disposal of the Govt. of Burma.

The services of Surg.-Lieut. H. J. Walton, M.B., F.R.C.S., I. M. S. (Bengal), are placed temply. at the disposal of the Govt. of the Punjab for employment on plague duty, from 12th Jan. 1898.

The services of Surg.-Capt. J. W. Grant, M.B., O.M., I. M. S. (Bengal), are placed temply. at the disposal of the Foreign Dept. from 27th Dec. 1898.

Surg.-Lieut.-Col. Dhanjisha Narroji Porakh, I. M. S., Surg. Gokuldas Tejpal Native Genl. Hosp., Bombay, retired from the service from the 14th March 1898.

Hon. Surg.-Capt. Daniel O'Leary, I. M. D., retired from the service from 21st Sep. 1897.

Asst. Surg. Henry Hesterford, M.D. has been transferred to the pension establishment.

Asst. Surg. Francis Joseph Salts, I. M. D. is dismissed from the service.

BENGAL GOVERNMENT.

Asst. Surg. Jogendra Nath Bose did duty as an Inspr. Med. Officer at the Plague Observation Camp at Kuriah Road Station, on the East Coast Ry., from 25th Aug. to 9th Oct. and from 20th Nov. to 20th Dec. 1897.

The services of Kumar Bhubendra Narayan, Offg. Civil Med. Officer of Darbhanga, are placed temply. at the disposal of the Cooch Behar State.

Asst. Surg. Nobin Chunder Dutt, Darbhanga Raj Hosp., is appd temply to have med. charge of the civil station of Darbhanga.

Miss Lila Brown and Miss Sarah Anthoni to be Inspr. Officers for the purpose of carrying out the provisions of the Epidemic Diseases Act, 1897, at Chakradharpur, Bengal-Nagpur Ry.

Asst. Surg. W. Sherrington to be Inspr. Med. Officer at Malwa, B. N. W. Ry.

Asst. Surg. O. A. B. Haegert to be an Inspr. Med. Officer at Channai Sta., E. I. Ry.

Mrs. R. Dutt to be an Inspr. Officer for the purpose of carrying out the provisions of the Epidemic Diseases Act, 1897, at Damukdia.

Dr. H. W. McCauley Hayte to act as Civil Med. Officer of Saran.

Asst. Surg. Upendra Narain Roy, Chapra Diap., held med. charge of the civil station of Saran from 13th to 29th Jan. 1898.

Asst. Surg. Hem Chunder Sen to act as Teacher of Materia Medica, Campbell Med. School.

Asst. Surg. Mohendro Nath Gupta, Raj Bahadur, Teacher of Materia Medica, Campbell Med. School, Sealdah, furlough for one year.

Asst. Surg. Benode Bhatary Ghosal did supy. duty at the Med. College Hosp. from 22nd Dec. 1897 to 12th Jan. 1898.

Asst. Surg. Chuni Lal Nandi, Cor's Bazar sub-div. and Diap., leave for three months, 11th Jan. 1898.

Asst. Surg. Nobin Chunder Dutt, Raj Hosp., Darbhanga, leave for one month.

Asst. Surg. Jogeshwar Mukherjee, leave from the 3rd Sept. to 1st Dec. 1897.

Asst. Surg. Wilkinto Chatterjee to do supy. duty at the Med. Coll. Calcutta, from 12th Feb. 1898.

PUNJAB GOVERNMENT.

The 120 months leave on medical certificate granted to Surg.-Capt. William Nott, from 29th Nov. 1897, is extended to 1st Dec. 1897.

Surg. Asst. Abdul Karim resumed charge Faridkot Diap. Datta, 17th Jan. 1898.

Surgeon-Major Genl. J. Chapman, M.D., D.S.I., I. M. S., D.R.C.P., I. M. S. and Surg. Commandant with the Govt. of India, General Service, sent out of India for eight months.

The following temporary Surgeon-Majors, Assts. in the Hoshiarpur Dist. were made from the 1st Jan. 1898:—Surg. Asst. Major Edmund, 6th Jan. 1898; Surg. Asst. Major, 6th Jan. 1898; Surg. Asst. Major, 6th Jan. 1898; Surg. Asst. Major, 6th Jan. 1898; Surg. Asst. Major, 6th Jan. 1898; Surg. Asst. Major, 6th Jan. 1898; Surg. Asst. Major, 6th Jan. 1898; Surg. Asst. Major, 6th Jan. 1898; Surg. Asst. Major, 6th Jan. 1898; Surg. Asst. Major, 6th Jan. 1898.

Surg. Asst. Umar-ud-din, from 1st Jan. 1898, Ludhiana, to Hoshiarpur from 12th Jan. 1898.

Surg. Asst. Bahmat Ali resumed charge at the Civil Surg. Ludhiana, 12th Jan. 1898.

Surg. Asst. Farish Singh resumed charge of his duties at the Civil Surg. Karnal Dist. 23rd Jan. 1898.

Surg. Asst. Shaib Ditta, Ludhiana, and Surg. Asst. Nihal, Jagraon, 23rd Jan. 1898, were appd. on special plague duty, Hoshiarpur Dist., from 6th and 7th Feb. 1898.

Surg. Asst. Labba Mal, Jullunder, having passed the English qual. exam. is entitled to the higher rate of his grade from 10th Feb. 1898.

Surg. Asst. Ganga Bishar, Ludhiana, having passed the English qual. exam. is entitled to the higher rate of the pay of his grade from 8th Nov. 1898.

Surg.-Major S. F. Bigger assumed charge civil med. duties of Kohat, 2nd Feb. 1898.

The following promotions and appointments among Civil Surgeons are published for information with effect from 31st Aug. 1898:—

Surg.-Major J. Clarke, Offg. Civil Surg., to be Civil Surg., 2nd class.

Surg.-Capt. D. T. Lane will be treated as having been confirmed as Supdt. Chenawan Central Jail from 31st Aug. 1898.

Surg.-Capt. H. M. Morris, Offg. Civil Surg., to be Civil Surg., 2nd class.

Surg.-Capt. D. T. Lane, to be Civil Surg., 2nd class.

Surg.-Capt. A. W. T. Baint-Sparks and Surg.-Capt. H. Smith, Off. Civil Surg., to be Civil Surgeons, 2nd class.

Surg.-Capt. A. Coleman to be Civil Surg., 2nd class, and Surg.-Capt. H. Smith Civil Surg. 2nd class, to revert to Offg. Civil Surg.

Surg.-Capt. A. W. T. Baint-Sparks, Civil Surg., 2nd class to revert to Offg. Civil Surg.

BOMBAY GOVERNMENT.

Asst. Surg. G. M. Dixon, L.M.S., privilege leave for two months.

Asst. Surg. Dorabhai Elaji Kothavala, L.M.S., to act as Supdt., and Med. Officer, Sind Dang, from 23rd Jan. 1898.

Asst. Surg. P. A. Cordeiro has been attached to Monsieur Haffkine's Laboratory at Bombay for duty from 8th Jan. 1898.

The services of Surg.-Col. G. W. E. Hay were replaced at the disposal of the Govt. of India from 11th Dec. 1897.

Asst. Surg. E. S. Bharucha has been appd. Med. Officer in charge Plague Flying Column No. 11 at Karad from 7th Feb. 1898.

Asst. Surg. J. P. Wadia has been placed under the orders of the Medical Officer of the Port of Bombay from 9th Feb. 1898.

Surg.-Major M. A. T. Collins, M.B., O.M., I. M. S., was on plague duty at Hubli from 9th to 13th Jan. 1898.

CENTRAL PROVINCES GOVERNMENT.

Asst. Surg. Waman Vihal Kana, Nagpur, Mayo Hosp., Nagpur, to the post of Asst. to the Civil Surg. Nagpur, from 4th to 25th Oct. 1897, and was re-appd. as such from 1st Nov. 1897.

Asst. Surg. Baidyanath Symak, Inspr. Med. Officer of Baidi Camp, Mandla dist., to do duty under Civil Surg. Jabalpur, from 27th Nov. 1897.

Asst. Surg. Baidyanath Symak to do duty under Civil Surg., Nagpur, 4th Dec. 1897.

Asst. Surg. Baidyanath Symak was deputed on plague inspection duty at the Ry. Sta., Nagpur, from 8th to 18th Dec. 1897.

Asst. Surg. Khado Chandra Ghose, on plague duty at Burhanpur, to do duty under Civil Surg., Nagpur, from 14th Jan. 1898.

The services of the following Licentiate of the Temple

1. School, Baku, have been temply. anticipated, as well as. Asst. for plague &c., duty, and have been posted to the owing duty:—

Vipendranath Gupta, 20th Dec. 1897, Raipur; Savathkur Mitra, 20th Dec. 1897, Raipur; Ali Ahmad, 22nd Dec. 1897, Nagpur; Abdul Hamid, 22nd Dec. 1897, Nagpur; and Hamid, 23rd Dec. 1897, Nagpur.

Asst. Asst. Vikrant Narsin to do duty under Civil Surgn., pur; from 20th Nov. to 24th Dec. 1897.

Asst. Asst. Vikrant Narsin to the Police Hosp. Raipur, n 24th Dec. 1897.

Asst. Asst. Lal Muhammad, Branch Dispy., Secnd dist., i change Lakhandes Poor-house, 17th Oct. 1897.

Asst. Asst. Vithal Moreswar to do duty under Civil gn., Sangor.

Asst. Asst. Vithal Moreswar to the Deeri Branch Dispy., gor dist.

Asst. Asst. Pratab Singh to duty under Civil Surgn. gor.

Asst. Asst. Bhondulal to duty under Civil Surgn. gor.

Asst. Asst. Bhondulal is placed on plague duty at the gor By. Stn. from 19th Oct.

Asst. Asst. Abdul Rahim, Katol Branch Dispy., Nagpur, to the City Branch Dispy., Sangor.

Asst. Asst. Abdul Fattah Khan to the Katol Branch py.

Asst. Asst. Deolal, Baloda Branch Dispy., Raipur dist., is nised the service from the date he was suspended by the il Surgn. Raipur.

r. Har Narayan Singh was deputed on plague duty, gor dist., from 17th Feby. to 28th Oct. 1897.

Asst. Asst. Chandra Bhan to do duty under Civil Surgn. gor.

Asst. Asst. Chandra Bhan was deputed on pñgue duty at a, Sangor Dist.

Asst. Asst. Abdul Karim is temply. apptd to the Behora non Dispy., Jabulpore dist.

Asst. Asst. Vithal Moreswar to do duty under Civil gn., Sangor.

Asst. Asst. Henry Peter and Devarsu Pillai, Burma ab., to Jabulpore to do duty under Civil Surgn.

N. W. P. AND OUDH GOVERNMENT

Asst. Surgn. Manmatha Nath Basu, from plague duty, raspur, to Sadar Dispy., Mirzapur.

Asst. Surgn. Manmatha Nath Basu, Sadar Dispy., Mirzapur, plague duty at that station.

Asst. Asst. Sirajul Humain, Colvin Hosp., Allahabad, to lar Dispy., Mirzapur.

Surgn.-Major C. C. Vaid, Civil Surgn., Hardoi, was on oial duty in connection with the Pilgrims' Camp at narea from 7th to 10th and from 18th to 28th Jan. 1898.

Asst. Surgn. Suresh Chandra Ghose, Sadar Dispy., Hardoi, d charge civil med. duties of that dist. from 7th to 10th l from 18th to 28th Jan. 1898.

Jabti Chanan Singh, L. M. S., to Civil Med. Dept. of these vñnces as an Asst. Surgn., 3rd grade, from 10th Jan. 18, and is posted to Baharanpur on reserve duty.

BURMA GOVERNMENT.

Asst. Asst. R. Govind Pillay is granted an extension of ve to 20th Jan. 1898.

Asst. Asst. P. Govind Pillay assumed charge Civil sp., Moulmein, 21st Jan. 1898.

Asst. Asst. K. Kanaren assumed charge Genl. Hosp., yah, 6th Oct. 1897.

Asst. Asst. K. Kanaren assumed charge of duties as dl. Officer, Arakan Hill Tracts, Paletwa, 18th Oct. 1897.

Asst. Asst. P. C. Ghose assumed charge of duties as Med. loer, Arakan Hill Tracts, 1st Dec. 1897.

Asst. Asst. Bistoo Charan Das assumed charge Lock-up, gok, Ruby Mines dist 1st Jan. 1898.

Asst. Asst. Amin Chand assumed charge Civil Hosp. itkyina, 28th Jan. 1898.

Asst. Asst. Raj Chander Barna relinquished charge Jail sp. Thayetwya, 1st Feby. 1898.

Asst. Asst. K. Kanaren assumed charge Jail Hosp., Thayetwya, 1st Feby. 1898.

Asst. Asst. P. Mahapatra, three months' leave 17th Jan. 18.

Asst. Asst. A. Rungaswami Iyer, leave for three months n 20th Oct. 1897.

G. O. O. G.

Surgn.-Capt. S. M. Dase, leave for 24 days, in extension.

The leave granted to Surgn.-Capt. A. O. Hubbard, L. M. S., is further extended by 4 days.

Surgn.-Capt. W. E. Hardy, leave for six months.

ASSAM GOVERNMENT.

Leave for six months is granted to Hosp. Asst. Asst. Chandra Bhaupl, in extension of the six months' leave granted, 2nd July 1897.

Hosp. Asst. Mahim Chandra Chandrahuni has passed the English Qual. Exam., 25th June 1898.

Hosp. Asst. Srinath Das, a supy. in the Khasi and Jaintia Hills dist. to the med. charge Nongpoh Dispy. in that dist., from 6th Feby. 1898.

DOMESTIC OCCURRENCES.

The charge for inserting a Domestic Occurrence is Rs. 1 for subscribers and Rs. 2 for non-subscribers, which should be forwarded in stamps with the announcement.

BIRTH.

WHITEHOUSE.—On 14th Feb at Jeypore, Rajputana, the wife of John Whitehouse, M.B. C. M., of a son.

MARRIAGES.

GIFFARD—GROSE.—On 5th Feb., at St. George's Cathedral, Madras, by the Ven Archdeacon Elwes, assisted by the Rev A. A. Williams, Alice Millicent Grose, daughter of Hon. Mr. J. Grose, I. C. S., to Gerald Giffard, I. M. S.

WILSON—OWEN.—On 8th Feb., at St. John's Episcopal Church, Edinburgh, by the Rev G. J. Cowley Brown, Incumbent, Andrew Robertson Wilson, M.A., M.B., C.M. (Edin.), of Trafford House, Liscard, Cheshire, younger son of the late Charles Edward Wilson, L.L.D., H. M. Senior Inspector of Schools, to Alice, daughter of the late Rev. Joseph Owen, D.D., Allahabad, India, and Miss Owen, 21, Athole-crescent, Edinburgh.

DEATHS.

REMFY.—On 11th Feb., at Truro, Cornwall, Leonard Remfy, M.A., M.D., F.R.C.S., aged 86.

WILSON.—On 13th Feb., at Sitapur, Oudh, Rev. P. T. Wilson, M.A., M.D., Missionary of the American Methodist Episcopal Church.

NOTICES TO CORRESPONDENTS.

J. F. F. (Bandiqui).—The whole subject of a special State diploma ranking below the L. M. S. degree of our Indian Universities, will shortly come under the consideration of the Council of the Indian Medical Association.

J. B. (Allahabad).—Retired but young Military and Civil Assistant Surgeons will find ready employment on the new railway lines that are being opened up in Egypt and South Africa. As far as we understand, the salaries for medical officers are good.

G. E. C. (Bandiqui).—Many thanks, next number.

Senior.—If junior Military Assistant Surgeons should not have the rank of Warrant Officers, then what about junior Army Surgeons? If your idea holds good, then Army Surgeons should not be Commissioned Officers. In no case can we ask for retrogression; it must be progress, upwards and onwards for our boys.

S. N. M. (Malakand).—If Storekeepers of Hospitals are trained and qualified medical men, they can be admitted into the Indian Medical Association. Please read the Rules of the Association.

ORIGINAL ARTICLES.

THE LOCALISED NATURE OF THE
MALARIAL POISON.BY SURGEON-MAJOR R. R. H. MOORE, M.D., A.M.S.
Jalapaahar, Darjeeling.

There is one characteristic of the poison of malaria which, I venture to think, has a vast etiological bearing, and to which sufficient attention has never been paid.

This characteristic is its peculiarly localised nature.

By this expression I do not mean that the poison is given off from a few localised areas only; the word localised refers strictly to the action of the poison, not to the place from which it is evolved.

The injurious action of the poison is closely confined to the spot where it is generated, its striking distance is a small one, its influence is circumscribed, it is a stay-at-home poison which does not venture out to attack the traveller; but, like the spider, spins its web and waits for its prey to come to it.

This is a fact of enormous significance from the etiological stand-point, and it is supported not by a few isolated observations only, but by a strong vein of well established opinion whose ramifications spread through almost the whole literature of the habits of malaria.

By giving to this peculiarity its full importance and studying it as a special entity, the issue becomes narrowed and the way is cleared for valuable investigation and reliable deductions. This simple aspect of the malarial question has never been studied in this way, and why? Because it has always been obscured by a mass of more or less contradictory, vague and unreliable statements, purely hypothetical, and which only gained a moment's acceptance on account of the uncertainty which surrounded the whole subject.

In a previous paper¹ I have endeavoured to show that the observations and arguments in support of the doctrine, that malaria is diffused through the atmosphere, and can be transported from place to place by the wind, are fallacious and unworthy of credence.

Once admit this and much of the obscurity is removed; the clouds lift and a clearer view presents itself to the observer.

The localised nature of the poison has to be studied under various aspects; it is the salient point in the observations that have been recorded regarding the immunity derived from sleeping at a slight elevation above the ground,—by higher levels, even when slight, being more healthy than lower levels,—by the exemption of vessels lying off malarious coasts,—by the class distinctions which the disease draws,—and by its nocturnal habits.

In addition to these there are two other generally accepted ideas which bear more or less directly on this point, viz., the supposed partial immunity enjoyed by natives,—and that new-comers to a malarious country are particularly susceptible to malaria.

I hope to be able to make it clear that these two ideas are erroneous, and have no foundation in fact.

The way in which my main thesis—the localised nature of the malarial poison—is expressed by modern French writers² is to be found in the following phrase “Son

germe est étroitement lié au sol;” the poison is closely bound to the soil; this idea runs like a keynote throughout the whole of KILSON and KISSER’s work on malaria; it occurs over and over again in various forms which shows the importance attached to it.

In their summing up they say:—“Malaria differs from dysentery and typhoid fever, which so often occur under similar circumstances, by the fixity and permanence of its places of origin; its germ is closely bound to the soil.”

Before proceeding further, it is necessary to understand that in malarious countries the malarial poison is not confined to well defined localities; it exists everywhere, some places may be more malarious than others, but no place is entirely exempt. That this is true has been amply proved for France; and if it is so in a temperate climate of this kind, and in a country which hardly deserves the name malarious, how much more so must it be in tropical and subtropical climates?

Regarding France it is well-known that whenever troops go out into camp, even in places supposed to be free from malaria, the disease appears.

It may be noted that they almost invariably go into camp in the late summer or early autumn months.

On this subject KILSON and KISSER³ give us the following information (p. 798):—“The development of malarial fevers in all camps, even in those which are established in the midst of plains reputedly healthy, proves that the germs of malaria, far from being confined exclusively to certain foci, are disseminated every where” In another place they say:—“These facts attest the existence of local fever-causing influences which are present in all camps, and often with remarkable intensity;” and again, “in our opinion nothing better demonstrates the influence of camps on the genesis of malaria than the epidemic which sprang up in the 10th Battalion de Chasseurs à pied encamped in huts, in the neighbourhood of Saint-Dié. Malarial fevers are very rare in the valley of the Meurthe, which presents none of the telluric conditions in presence of which it usually arises; yet these fevers developed in the form of spring and summer epidemics for three consecutive years, amongst the soldiers. In the years 1881 and 1882, the proportion of those attacked amounted to one-fifteenth and one-sixteenth of the whole strength; yet during this time not a single case of malarial fever was observed in the civil population.”

These facts are very striking and very important, and are alone sufficient to prove the localised nature of the poison.

They amount to this, that the malarial poison exists throughout the whole of France, why then does not every one suffer from the disease? Because the poison is localised; it is not diffused in the air.

Why do the soldiers get it when in camp? Because they go to the poison, they lie either upon the ground or else, very close to it, while the inhabitants in their well-built houses are exempt.

In Algiers, the same authors say “malarial fevers are everywhere.”

Of India, DAVIDSON⁴ says:—“throughout the whole of India there is no province or extensive district entirely free from malarious diseases.”

It may then, I think, take it for granted that in mountainous countries the poison is to be found everywhere.

A slight elevation gives immunity from malarial fever. The elevation may be of two kinds: a raised structure or elevated ground.

As a well-known fact that the natives of many malarious countries live in raised structures, and it has long been accepted that by doing so they escape malarial fevers. HUMBOLDT mentions that this custom prevails amongst the Gevases of the Outback. In New Guinea, WALLACE says that the houses are elevated 15 feet above the ground on a forest of poles.

In Burma we find the same thing, and the following incident was related to me by Surgeon-Major FRYER, A. M. S. regarding it. He and some other officers were going to occupy a Burmese house. All the officers slept above, but in spite of Surgeon-Major FRYER's warning the servants, except his own, were obliged to sleep below; the result was that they all got fever, and more than half of them died, while none of those who slept above were affected.

JACQUOT⁴ tells us that, "in Italy and along the shores of the Mediterranean, the ground floors are never occupied by those who can avoid them, that when the Corsican peasants are obliged in the autumn to leave their hill towns for the purpose of working in the fields below, they never fail if possible, to return home in the evening; when, however, the distance is too far, they construct temporary cabins in the trees to which they ascend for the night."

And TOMMASI-CRUDELI mentions the fact that people sleeping a few metres above the ground do not contract fever.

It is however unnecessary to enlarge further on such a well-established fact.

Regarding elevated ground, it is well-known that the inhabitants of mountainous countries never build on low ground; they avoid the bottoms of ravines and erect their dwellings on the hill sides.

PARROTT⁵ mentions a case where, in the midst of a malarial epidemic, a slight elevation gave comparative immunity.

"After the campaign in Brabant in 1749," he says, "our army suffered very severely from malarial fevers in cantonments near Eyndoven. There were two villages near Eyndoven called Lind and Zalst, the one ten and the other 14 feet, above the water level, and it was observable that the soldiers kept their health much better in both these places than in any other of the cantonments."

The country in which the cantonments were situated, it may be remarked, consisted of flat barren sand with water within two or three feet of the surface.

I need not, however, say any more on this subject, as my object is not to prove what is universally admitted, but merely to draw attention to these facts as casting a sidelight upon the localised nature of the malarial poison.

I have in a previous number¹ given instances of the immunity enjoyed by the crews of vessels lying close to malarious coasts, so will pass on to what I call the place distinction which "malaria" draws.

PLACE DISTINCTIONS.

This peculiarity was noticed by PARROTT⁵ regarding the fever in Holland. He says:—"The officers were not so subject to it as the common men * * * the cavalry, who had aloaks * * * were less liable to fall ill; others who belonged to the army but lay in quarters, were least of all affected."

The same thing was noticed in Hong-Kong by Surgeons HENKMAN⁶ and SWELL⁷, who remarked that the officers suffered less than the men, and the merchants least of all.

SWELL⁷ also says that "while the soldiers doing ordinary duty were decimated by fever, their comrades, who were in prison, many of them drunkards, some of them undergoing long sentences, remained in good health." Of course the prisoners had to be well housed for security.

Two other cases of some interest are mentioned by DAVY:⁸ "In Ceylon during the rebellion, October 1817 to October 1818, at one station in the district of Welisara, every white soldier sent there was attacked with fever except the Commanding Officer and the medical officer, who were least exposed," again in the same rebellion, "a party, seventy strong, was formed relieve a post in danger, they had to fight their way there and back, and sleep one night in the open air; every man was taken into hospital with fever, except the Commanding Officer."

The same holds good in India at the present day. Officers, women and children suffer less than men.

In 1895 the admissions for intermittent fever per 1,000 in the Bengal Command were for men, 249.9; women, 133.9; children, 82.8

All this points to the fact that the poison is not diffused, it is extremely localised, and those suffer most who are most exposed to it.

NOCTURNAL HABIT.

That malaria is nocturnal no one denies and this is a very remarkable thing, in respect of which malaria stands apart from all other specific diseases.

Considering that malarial fever is supposed to have an incubation stage of somewhere about 14 days, for it is very indefinite, how has it been possible to decide whether the poison entered the system by day or night?

The nocturnal habit is, in my opinion, established on firm grounds, and argues against the incubation theory, which is not.

The best and least controversial observations in support of it are afforded by the experiences of ships touching at malarious ports; in these cases there is a general consensus of opinion, that when the crews go on shore, it is only those who pass the night there who contract fever.

Observations of the kind have been recorded by FERGUSON⁹ BLAIR,¹⁰ DAVY,¹¹ DUTHOULET,¹² and the following will be found in LAND¹³.

"Two men-of-war the 'Phoenix' and the 'Hound,' made the same voyage to the Gambia, and stopped at the same time at St. Thomas, though both crews were on shore during several days basking and sunbathing, and taking in water, it was remarked that only those who stayed on shore at night took fever."

Henry has said of the Roman Campaigns that one may well wonder if it is by day, while so much a few hours' rest would mean severe and perhaps fatal fever.

It is a nice problem what happens of the poison during the day time, does it die? Or does it return to the ground to re-issue the following evening? No one has been able to tell us.—

One thing, however, appears certain, and that is, that it does not travel, and is not conveyed from place to place.

A very pretty example bearing out the main contention of the paper was recorded in this journal, January 1st 1898, by Surgeon Major RONALD ROSS, I. M. S., regarding a slight epidemic that occurred in the men of his regiment at Secunderabad.

"With respect to the causation of the disease," he says, "it may be stated that the regiment in which the cases occurred, numbers some 800 persons, and is stationed in lines of huts about a mile from the marshy origin of a large tank. On first thoughts the marsh would be declared at once to be the origin of the malaria, but there are reasons to traverse this view."

"For instance, the disease showed a tendency to infect certain portions of the lines more than others, though all portions are equally exposed to the marsh air. Thus out of 70 recruits who lived together in a stone built house close to the rest of the lines, not one was attacked, though 100 of the remaining 730 men suffered. Again, in two houses all the inmates suffered, namely, father, mother, and children." "Such facts as these," he adds, "seem to point to a very local origin of the disease."

This is by no means an exceptional case, numbers of similar instances are to be found in the literature of malaria.

The recruits, we see, many probably new-comers to the place, were exempt. They were lodged in a stone-built house. It is a curious thing about malaria, and a thing to which several examples given in this paper point, that it has an intense dislike to a well-built house.

In the case of Hong-Kong, in this Journal for 16th December 1897, I have showed in what a marked manner the disease diminished as soon as the troops were lodged in fairly well-built barracks.

Partial immunity enjoyed by natives; and new-comers particularly susceptible to the disease.

Perhaps of all the many varied ideas which pass for current coin in the malarial market, there is none whose value is less questioned than the partial immunity enjoyed by the native.

In my opinion, however, there is not a particle of truth in it; there is no such thing as immunity, partial or otherwise, where malaria is concerned.

If figures can prove anything, the following table proves this up to the hilt.

Table showing the annual admissions per 1,000 for Intermittent Fever amongst European and Native Troops in India. Average annual strength. European troops over 65,000. Natives over 125,000.

Year.	EUROPEAN TROOPS.				NATIVE TROOPS.			
	1896	1897	1898	1899	1896	1897	1898	1899
1890	564.1	500.2	377.0	283.6	520.0	608.0	380.1	481.8
1891	542.0	383.1	240.0	200.0	427.0	448.1	408.2	483.4
1892	679.1	408.0	100.2	200.0	500.0	533.3	541.8	545.0
1893	500.0	410.2	189.1	443.6	500.0	511.1	537.8	521.8
1894	411.0	484.4	108.7	461.0	570.4	400.7	515.2	528.0
1895	586.0	260.0	110.0	400.0	507.0	500.0	500.0	540.0
Years of excess European troops	NH	NH	NH	NH
Years of excess Native troops.	NH	NH

This table is compiled from the Annual Reports of the Sanitary Commissioner with the Government of India, and the numbers are sufficiently large to remove all objections on that score.

It shows us that while in the whole of India, and in Bengal, the disease preponderated equally during the six years tabulated, the Europeans and natives having each three years of excess, in Bombay the natives suffered most in five out of the six years, and in Madras they suffered most every year without exception.

Now when we consider that about 15,000 fresh European troops land in India every year, who are supposed to be particularly susceptible to the disease, and that in spite of this, the native troops actually suffer more from malaria than the European troops, there is only one conclusion to be drawn, and that is, that,

The supposed Partial Immunity enjoyed by the Native does not exist.

It is easy enough to understand how the idea arose; at first the negro was supposed to be altogether immune, why? Europeans who visited and travelled in their country got fever, the natives apparently did not, therefore they were immune. But no attention was paid to the important points, that while the natives were living according to their usual customs and habits, the travellers and visitors were exposing themselves in all sorts of ways, perhaps in camps or in hastily constructed houses, and taking all sorts of liberties in a climate and in a country they did not understand.

Of course the idea of the immunity of the negro is now exploded.

These ideas have always found a ready acceptance, because they tended to bring malarial fevers into line with what is known of other specific fevers, as for instance, the fact that small-pox, measles, and scarlet fever rage with special virulence, when introduced into a place where they were formerly unknown.

The opinion that new-comers are specially susceptible to malaria, to which KILSON and KILSON attach some importance, is founded upon erroneous or misinterpreted observations. In support of it, for instance, these authors quote PRINGLE to the following effect (p. 307):—

"PRINGLE was astonished to observe that the English

troops, on their campaigns in Holland, paid a much larger tribute to malarial fever than the inhabitants.

Since that time, the observation has been repeated many times, notably in the Flushing Expedition, when fever decimated the English expeditionary corps, while it hardly affected the general population.

These and many other observations of the same kind are supposed to demonstrate that, given the same amount of exposure to the malarial poison, new-comers, in all countries are more susceptible to malaria than the inhabitants.

The crux is in the words "given the same amount of exposure," for if the exposure cannot be shown to be the same, the observations prove nothing, and yet who can say that it was the same? Is it not very obvious that it was altogether different? Suppose the comfortable burgher of Holland had been turned out into the English cantonments, situated on bare sandy ground with water only a foot or two below the surface, (FERGUSON says that at Rosendaal and Oosterhout it was only a few inches below), and the English troops housed in their well-built dwellings, who would have suffered most from fever? Most people will, I think, be ready to admit that it would not be the new-comers.

The question is altogether one of exposure; the troops were exposed to the poison, the others were not. If there can possibly be any doubt on the point, the experience of the troops in France must be sufficient to dispel it once and for all; for it cannot possibly be argued that the reason they suffer more from malaria than the civil population is due to the fact of their being new comers. If the troops and the civil population were to change places, the fever incidence would also change; the poison is localised, those living under the conditions inseparable from camp life go to the poison, the others do not.

Finally, take the case of the Wanowrie and Ghorpuri Barracks in Poona.

"The average admissions from paroxysmal fevers in these two barracks during a period of eleven years was:—

Ghorpuri, 652.09.

Wanowrie, 324.85.

This instance shows the influence of local conditions in the causation of fever. ("DAVIDSON.")

Now I will venture to say that no matter what troops are put into Ghorpuri Barracks, they will suffer more from malaria than any other body of troops in Wanowrie.

The reason is as simple as the fact is clear; Ghorpuri is situated on low-lying badly-drained ground, while the opposite conditions prevail at Wanowrie, though they are only about a mile apart.

The question is only one of exposure to a very localised insanitary influence.

We all know that many Europeans spend many years in India without contracting fever; it is not because there is no malaria where they happened to live. It is also well-known that by taking a few simple precautions Europeans can, and often do, traverse very malarious places with impunity, as Dr. BLANC and Mr. FAIDEAUX did in Abyssinia.

When marshes cause malarial fevers, it is only those living close to the marsh who get the disease, the same

holds good for malaria arising from rice cultivation and inundations.

We find an abundance of well-authenticated facts in support of the localised nature of the poison; this same poison, which has been supposed on the most flimsy evidence to sweep across the country side and ascend mountains on the bosom of the wind!

In tropical countries a very slight degree of exposure is sufficient, in less malarious, or in other words, in temperate climates a man must be on the ground to be affected. A man sleeping in the open gets fever; another in a house close by is exempt. In colder and non-malarious countries, we know that sleeping on the open ground is not conducive to health, but the diseases which would be likely to arise from it, are not to be found amongst the specific fevers.

—10:—

A NOTE ON ABRUS POISONING.

By SURGEON-MAJOR G. M. GILLES, M.B. Lond., F.R.C.S. Eng.
I.M.S.

Sitapur, Oudh.

THE subject of abrus poisoning is one of such considerable medico-legal interest in India that it is somewhat surprising that more has not been written on the subject; but the only contribution of any importance that I can recall is the valuable and laborious investigation, published in pamphlet form, by Surgeon-Majors WARDEN and WADDELL some 14 years ago.* Their work was mainly directed to the determination of the question as to whether the poisonous effects of abrus were due to the intrinsic effects of the seeds themselves, or to the products of a fermentation within them, arising from the action of *bacilli* that had been described by certain observers. It may, I think, be conceded that they completely disposed of the bacillar theory, and clearly demonstrated that the peculiar effects of the drug are due to a peculiar body isolated by them, which they named abrin.

This investigation dealt mainly with the chemical and physiological side of the question to which I have little or nothing to add, and it is mainly to its medico-legal side, and especially the detection of the drug in the body of the victim to which I would desire to draw attention; for although there can be no doubt that thousands of cattle are yearly destroyed in this way, and it is only too probable that abrus is occasionally the agent employed in the commission of murder. I have met with several officers of considerable Indian standing who had never so much as heard of the subject.

Everyone knows the pretty red and black seeds used as weights by goldsmiths in this country—"ratti" as they are termed.

* The non-bacillar nature of abrus poison. G. J. H. Warden and L. A. Waddell, Calcutta, Bengal Secretariat Press, 1894.

the seeds are first carefully husked and are then very finely ground on a curry stone, and mixed into a stiff paste with a little water. The paste is then rolled into small conical masses, each weighing dry about 15 grains. They measure about $1\frac{1}{2}$ inches in length by about $\frac{1}{4}$ inch in diameter at the base, and at the other end are brought to a very sharp point. When dry, these masses are surprisingly hard and are quite capable of being driven into the skin after the fashion of an arrowhead. It is likely enough that some of these experts add other ingredients, but experiment 2 shows that they have no more effect on the result than the spices and with the Indian rot-wallah loves to add to his heaven, and as a matter of fact, I could find no trace of any thing else but finely ground abras seed in a set of needles taken by the police from a cattle poisoner who was convicted in this district. A small piece of hedgegick about $\frac{1}{2}$ inch thick and 4 inches long is hollowed out at each end to a depth of about $\frac{1}{2}$ inch, the diameter of the hole being about the same as the depth, and the ends are wedged into these holes by means of a strip of rag bound round their base, the object being to hold it just firmly enough to enable it to be struck into the animal, but yet not so tightly as to prevent its remaining in the wound

As a matter of fact, both the seed and the seeds can be eaten either by man or animals with perfect impunity, but if introduced beneath the skin, they produce a train of symptoms which result, in the course of two or three days, in death.

The local reaction is however so small, and the early symptoms so obscure and little noticeable that death appears to be extremely sudden. In spite of this, however, they are so little like the symptoms of ordinary poisoning that, in the majority of cases, no suspicion is aroused.

This peculiar crime is, as a matter of fact, the indirect outcome of the sacredness of cow life in India, combined with the fact that the Hindu is quite willing to shelter his tender feet in leather shoes provided he has nothing to do with their manufacture. As the hides of animals that have succumbed to disease are naturally not of the best quality, and the supply is limited and uncertain, the Chamars secretly poison cattle with abras needles in order to provide skins as required in good condition.

The unfortunate cultivator is thus robbed of his means of subsistence, so that the Chamar may reap the small profit he gains on preparing the hide. Unscrupulous as the crime is from the ordinary point of view, it is doubly so from a Hindu stand-point, and in any other country in the world, public opinion would secure the detection of the miscreants with the same certainty that a vulpicide would be tracked down in an English hunting county.

The Chamar's *modus operandi* is as follows:—The seeds are first carefully husked and are then very finely ground on a curry stone, and mixed into a stiff paste with a little water. The paste is then rolled into small conical masses, each weighing dry about 15 grains. They measure about $1\frac{1}{2}$ inches in length by about $\frac{1}{4}$ inch in diameter at the base, and at the other end are brought to a very sharp point. When dry, these masses are surprisingly hard and are quite capable of being driven into the skin after the fashion of an arrowhead. It is likely enough that some of these experts add other ingredients, but experiment 2 shows that they have no more effect on the result than the spices and with the Indian rot-wallah loves to add to his heaven, and as a matter of fact, I could find no trace of any thing else but finely ground abras seed in a set of needles taken by the police from a cattle poisoner who was convicted in this district. A small piece of hedgegick about $\frac{1}{2}$ inch thick and 4 inches long is hollowed out at each end to a depth of about $\frac{1}{2}$ inch, the diameter of the hole being about the same as the depth, and the ends are wedged into these holes by means of a strip of rag bound round their base, the object being to hold it just firmly enough to enable it to be struck into the animal, but yet not so tightly as to prevent its remaining in the wound

After the seed is driven into the animal, the Chamar then turns the animal round, and the poisoner then strikes a second stab by merely turning the animal round, so that the animal has time to move. Thus, according to the Chamar, the animal creeps up to his victim and plants the seed; and in this manner; the part chosen being generally the soft skin of the neck, just in front of the shoulder. As a general rule, only about half an inch of the slender, pointed part penetrates the skin; the rest, as a rule, being broken off flush with the wound. Speaking generally, I doubt if more than two or three grains are introduced fairly beneath the skin, so that, assuming both strokes to reach home, the maximum dose must be about 6 grains and the minimum about 2 grains; but probably the smaller dose is sufficient to prove fatal in the majority of cases.

My prisoner, who, once convicted, was quite willing to describe his method of working, states that, as a rule, the animal dies within three or four days of the blow, but is only obviously ill for a few hours before the fatal termination. Some, of course, escape after a few days' illness, but two out of three of those operated on, die.

About three years ago, an animal of my own was destroyed in this way. One morning, the *gunalla* reported that the yield of milk was less than was customary, but the assertion was regarded as one of the customary wiles of these gentry to secure a larger proportion of the milk for their own use, especially as the cow seemed to be quite in its usual health. The next day the yield was even less, but there was nothing in the appearance of the cow to suggest illness, as it was calmly ruminating in its usual fashion. Towards evening, however, the animal was obviously ill and weak, but showed no obvious indications of distress, and I was still under the idea that the animal's condition was due to some malpractice on the part of the *gunalla*.

The next morning the cow was found dead. My attention having been drawn to the subject by a complimentary copy of Dr. WARDEN and WADDELLS' work sent me long ago, by the latter, I examined the body very carefully, and with some difficulty discovered on the right side of the neck a small oedematous swelling, in the centre of which was what appeared to be a small abrasion, just such as might be inflicted by the puncture of a thorn or by an irritated insect bite. On incising this swelling, I without any difficulty found imbedded in the bones some paste-like material, which I afterwards identified as powdered abras seed, by comparison of the microscopical appearances with a section of a seed. On opening the body some irritative changes could be made out in the intestine, but speaking generally, there was really nothing to suggest either disease or poison in any of the organs. Such deviations from the normal as were visible agreed well with the appearances described in the pamphlet, but were none of such a character as to attract attention, unless specially looked for.

The poisoner was never traced, but I took care that no Chamar should benefit in the least by either hide or meat, by burying the carcass a good six feet deep without their assistance. If Hindus who lost cattle under suspicious circumstances uniformly pursued this plan, the crime would probably die out.

At the commencement of June last my attention was again called to the matter by a very complete set of

abras, following implements being sent me by the magistrate, with the enquiry as to whether they contained anything capable of being used in cattle poisoning. The previous instance of my own cow having led to my studying the microscopical characteristics of abras seed as found in the tissues, I determined to investigate the same myself.

The set of implements was a very complete one, and consisted of a couple of the handles already described with strips of rag tacked into the cavities in their ends, ready for use, and about a dozen abras needles carefully stocked in a neat little bag made of a piece of an old dhoti.

In order to determine the composition of the *sui*, a portion of one was softened in water and examined under the microscope in comparison with a section of a genuine abras seed; and, as far as I could see, the *sui* contained no material that was not easily referable to some part or other of the husked seed.

To establish the toxicity of the material, the following experiments were conducted:—

Two kids were taken, and a portion of a *sui* introduced beneath the skin of the one and a similar quantity of abras powder beneath that of the other.

As will be seen, the symptoms and post-mortem appearances were absolutely identical in both cases.

For the details of the symptoms exhibited by the animals under experiment, I am indebted to one of my assistants, GJADER TIWARI, who bestowed great pains in keeping the animals under continuous observation.

Experiment 1.—14th June 1897 at 8 A.M. A healthy kid weighing 8 lbs was taken, its temperature being 103.8. A punctured wound was made in the skin of the neck by thrusting a narrow Paget's bistoury obliquely beneath the skin for about 1½ inches.

A morsel of the "*sui*" confiscated from the cattle poisoner, weighing 1 grain, was introduced into the track of this wound and pushed in as deeply as possible by means of a director. In the preparation of the instruments and of the animal all ordinary antiseptic precautions were observed, but the *sui* material was of course just as it was obtained from the poisoner.

At 11 A.M. it took the test with its usual appetite, and at noon it still seemed none the worse for the dose. At 1 P.M. it was still walking about, but was seen to be shivering violently. At 4 P.M. it again sucked a little milk, but was obviously feeble.—At 6 P.M. the temperature was 106°; at 8-30 P.M., it again took a little milk. There had evidently been but little urine evacuated, as it had gained half a pound in weight since the morning. The weakness had greatly increased, and it was bleating as if in distress. At 10 P.M., it was bleating continuously, and frequently fell when attempting to stand. At midnight it was shivering violently and unable to rise: if placed on its feet, it at once fell, and it could not even lift its head from the ground. Half an hour later it attempted to suck but soon after became unconscious, though still bleating faintly every four or five minutes. It died at 2 P.M.

Post-mortem.—There was little abnormal to be observed. Both pleural cavities contained a considerable amount of clear straw coloured fluid, and the lungs were somewhat congested and of a peculiar pinkish color. There was no

fluid in the pericardium. The heart was relaxed, and its cavities filled with dark coagulated blood. Locally only a little edema could be made out; the tissues being rather paler than normal. On sitting up the track of the puncture the remains of the *sui* softened down to a paste could easily be made out.

Experiment 2.—A healthy kid weighing 6 lbs. was treated in the same way at 8-30 A.M. on 14th June, the only difference being that, in place of the *sui* material, a grain weight of powdered but unhusked abras seed was introduced. The course of symptoms was almost exactly similar to the first case.

It took milk at 11 A.M., and at 1 P.M. was seen to be shivering violently. At 4 P.M. it again sucked and was beginning to bleat. At 6 P.M. its temperature was 105.2. There was great weakness and it could not take the test. At 9 it was bleating continuously, and by midnight was in a helpless condition. It also died about 2 P.M. On post-mortem the appearances were identical with those observed in the first experiment.

The condition of the heart and lungs was the same, and there was the same amount of pleural effusion and absence of local reaction.

Experiment 3.—On 16th June, a healthy paisah bitch weighing 29 lbs. was taken. Temperature 101.6. In view of the very rapidly fatal issue of the first two experiments, I determined to employ a very small dose and accordingly introduced beneath the skin, after the method followed in the two first experiments, one centigramme of *sui* material carefully weighed in a chemical balance. This was done at 7 30 A.M. and up to 3 P.M., no symptoms were observable, but at half past three she began to shiver and this shivering continued till 6 P.M., when it ceased. At 5 P.M. the temperature was 106.2. At 1 A.M. she was very restless, walking about as far as her chain would allow, and at 6 A.M. the shivering returned. There was a certain amount of edematous swelling about the site of the puncture, the ears were drooping and the animal looking depressed and ill. At 7 30 A.M. the temperature was 105.4 and she ate a little bread and milk. At half past eight the shivering had ceased, but she was ill and weak all day. At 5 P.M. the temperature was 104.4, ate a chupatti and 8 oz. milk. All night was very quiet and difficult to rouse.

18th June.—Morning temperature 105.4. The swelling of the neck has increased; the animal is very weak and with difficulty can be made to stand.

Evening temperature 105.2. The swelling of the neck is very marked; she is weaker and refuses all food. If put on her feet, she stands for a little while and then falls. The ears and neck are drooping, and the animal very ill, but no definite paralysis can be made out, but only a general extreme weakness. The pupils are somewhat dilated.

19th June.—Morning symptoms much the same; temperature 104.2, in evening 104.2; she is better, and can get up without help; drank a little milk.

20th June.—Is better; temperature 104; evening temperature 103.4, and is taking a little food.

21st June.—Morning temperature 103.8; swelling of neck less; the animal is more lively and obviously recovering, and takes food fairly well. Evening temperature 102.

22nd June.—Seems nearly well and eats with appetite; breathing temperature 102. There is a little discharge of blood-stained matter from the wound, which hitherto has remained quite dry.

23rd June.—Quite well; temperature 102; weight 26 lbs. There is no discharge.

24th June.—Temperature 101.6. There is some discharge from the wound. This discharge continued for a couple of weeks from a small sinus along the course of the puncture, but there was never any diffused suppuration, or any greater discharge than would be naturally set up by a small foreign body introduced beneath the skin. Now while, in the main, the symptoms exhibited by these animals agree with those described by WARDEN and WADDELL, *loc. cit.*, they differ in this very important particular, *viz.*, that while these authors found the temperature uniformly depressed, in all my three cases there was shivering, with a marked rise of bodily temperature. An observer knowing nothing of the scrap of vegetable tissue in the neck would have certainly concluded that these animals were suffering from an acute septicæmia. That this could hardly have been due to simultaneous infection with any of the pyogenic bacteria is shown by the absence of any suppuration worthy of the name in the dog, which after a severe struggle for life, recovered. In this animal, no suppuration occurred till it was practically out of danger, and the scanty discharge that appeared during convalescence can hardly have been due to anything but a secondary infection of the wound tract, nor would its amount at any time have sufficed to account for any appreciable degree of fever.

It is true that I purposely avoided any attempt at sterilizing the material introduced beneath the skin, because the active principle, *abrin*, isolated by WARDEN and WADDELL, was shown by these authors to be so unstable as to be rendered inert by any of the ordinary methods of sterilization.

It is possible that the difference of the species of animal experimented upon may be the origin of this discrepancy, for these gentlemen made their observations upon fowls and cats, while I found kids and a dog more conveniently obtainable.

The point, however, which I wish more especially to lead up to is the practical one of the detection of the evidences of the crime in the bodies of the poisoned cattle.

My confidential captive informs me that the spot struck at is almost universally the comparatively delicate skin of the neck, where the stroke can pin it against the projection of the shoulder, and that it is very rare for the blow to be attempted to be landed in any other position. Further, from obvious considerations, the right side is that generally attacked. In all cases therefore of inexplicable cattle mortality, this portion of the integument should be most carefully scrutinized, and if no indication of a puncture be perceptible externally, the skin should be carefully reflected, when the small extravasation at the site of the inoculation will indicate its position in a most easily recognizable fashion.

The puncture, having been thus discovered, should be carefully slit open from the raw side, when no difficulty will be experienced in discovering the *abrin* paste, which

looks much like a morsel of softened chapatti imbedded in the tissues.

If a little of this material be taken up and placed beneath the microscope, it will be found that the seed has been so finely and carefully powdered that it is resolved into its component cells.

The portion of the seed used by the prisoner consists of the bulky cotyledons only, the rest of the embryo being so small that it may be neglected.

These cotyledons are composed of a peculiarly hard sclerenchyma, which has a very characteristic appearance. The cells have very thick walls which are pierced by five or six tubules to admit of continuity of the protoplasm of adjacent cells. Though ivory hard, the cell wall is almost colorless, and of very uniform transparent structure, no sign of lamination being observable.

These appearances are well shown in the microphotograph which accompanies this note, the tubules being well shown in a sharply focussed cell near the middle of the plate. The negative was taken from the pulp remaining in the wound of the kid which was killed by one of the confiscated "*susa*," and will, I think, form a good guide to the recognition of the material as found in poisoned cattle.

The microscopical appearances are so characteristic, while the chemical re-actions of *abrin* are of such a general character that, in the present state of our knowledge, it would appear better to rely on the former alone.

The state of the law with regard to this peculiar and dastardly crime is most unsatisfactory. From the nature of the case, it is well nigh impossible to secure evidence of the actual commission of the crime, and the mere possession of the implements is unfortunately not criminal. It is obvious, however, that outside a technical museum, or the cabinet of the medico-legal expert, such things can have no place in the legitimate possessions of any honest person, and in view of the immense amount of loss annually inflicted on the unfortunate cultivator, the matter

May not the injection of certain animal secretions such as bile act as an antidote? There are all points well worthy of investigation, but I had neither time nor the energy of health to take them up, as is so often the case in this tantalizing country, where problems of a most interesting character are continually cropping up, but one is deterred from attacking them by the pressure of official work, and the lassitude of a tropical existence.

By J. MORTON, M.D., L.S.C.P. & S. Edin., L.F.P. & S. Glas.
Muscoria.

"The appearance of the matter discharged in the locomotive is very various with respect to consistence and

the leucorrhoea, depending on disease, as from the irritation of the uterus, or from the disease of the stomach or bowels. The view of leucorrhoea as a disease is very evident. But leucorrhoea is not a disease, it is the present condition of the uterus, the present knowledge.

The leucorrhoea, of which I am now treating, as ascertained by the various circumstances before mentioned, seems to proceed from the same causes as that species of menorrhagia, which I suppose to arise from the laceration of the extreme vessels of the uterus. It accordingly often follows or accompanies such a menorrhagia, but though the leucorrhoea chiefly depends upon the laceration mentioned, it may have proceeded from irritations inducing that laceration, and seems to be always increased by any irritations applied to the uterus. We would have liked to have known what was the nature of the irritations that were applied to the uterus, whether they were caustic, or the actual cautery, but unfortunately there is no further explanation. "Some authors have alleged that a variety of circumstances in other parts of the body may have a share in bringing on, and in continuing this affection of the uterus now under consideration (he mentions before that there is no topical affection of the uterus). But I cannot discover the reality of those causes; and it seems to me that this leucorrhoea, excepting so far as it depends on a general debility of the system, is always primarily an affection of the uterus; and the affections of other parts of the body, which may happen to accompany it, are for the most part to be considered as effects, rather than causes. The effects of leucorrhoea are much the same with those of menorrhagia; inducing a general debility, and in particular a debility in the functions of the stomach. If, however, the leucorrhoea be moderate, and be not accompanied with any considerable degree of menorrhagia, it may often long continue without inducing any great degree of debility; and it is only when the discharge has been very copious, as well as constant, that its effects in that way are very remarkable. But even when its effects upon the whole body are not very considerable, it may still be supposed to weaken the genital system; and it seems sufficiently probable that this discharge may often have a share in occasioning barrenness. The matter discharged in the leucorrhoea is at first generally mild, but after some continuance of the disease it sometimes becomes acrid (the young practitioner must not conclude too hastily that an ulcer exists in the uterus when the matter discharged is acrid. Practice has afforded many instances where the matter has excreted the pudenda, and yet no ulcer existed); and by irritating or perhaps eroding the surfaces over which it passes, induces various painful disorders."

And now we come to the most important part of the discussion—the treatment. Professor Cullen treated his cases as follows:—

"As I have supposed that the leucorrhoea proceeds from the same causes as that species of menorrhagia, which is chiefly owing to a laceration of the uterine vessels, it must be treated, and the cure attempted, by the same means as described in para. 322 for the cure of menorrhagia, and with less reserve in respect of the use of astringents."

The following form is very convenient:—

R	Rubigin Ferri	℥i
	Cort. Peruv.	℥i
	Syrup Simpl.	q.s.
	M. F. Elect.			

The dose of this electuary is to be varied according to the constitution, a quantity the size of a nutmeg twice a day is usually given.

The best form of Chalybeate water, in these cases, are the mineral waters which contain iron dissolved by fixed air. Chalybeate waters should not in this disease be drunk in such large quantities as to pass off by stool. A gill taken every three or four hours throughout the day, with a spoonful of port-wine, is more efficacious than a pint, or even a quart taken at once in the morning. The dose, however, of these waters varies according to the strength of the particular water we use. Along with the Chalybeate water, a scruple or half a drachm of Peruvian bark may be given twice a day.

The following form is very agreeable, and is at the same time singularly efficacious:—

R	Extract Cort. Peruv	℥i
	Extract. Campecheno.			
	Extract. Glycyrrh	aa 3ss.
	Mucilag. Gum. Arab	q.s.
	M. F. Elect.			

The dose is half a drachm or two scruples twice a day.

Practitioners recommend in these cases, a nutritive but not a heating diet, as mucilaginous broths made with rice, especially raddi-broth, jellies of all kinds, except those that are highly seasoned. Port wine must be prescribed in a moderate quantity, according to the habits of the patient.

As the leucorrhoea generally depends upon a great loss of tone in the vessels of the uterus, the disease has been relieved, and sometimes cured, by certain stimulant medicines, which are commonly determined to the urinary passages, and from the vicinity of these are often communicated to the uterus. Such, for example, are cantharides, turpentine, and other balsams of a similar nature. The practice here recommended is not without danger, and must not be followed, except with great caution and circumspection. When the other means fail in producing relief, we may then have recourse to these balsams, or join them to the tonic astringents, as,—

R	Gum Oliban			
	Terebinth Venet			
	Alum			
	Tort. Japonic	aa 3℥
	Sal martia	℥ss

M. F. mass in pilulis aequal No. 60 dividend.

Two or three of these pills may be given twice a day or oftener.

R Balsam Copaiv 3i
Vitel. Ovi No. 1

Tere in mortar, marmor, at adde gradatim.

Aq. fort 3vii
Syr. Simpl. 3i
M. F. Emulsio.

The dose of this emulsion is 2 or 3 spoonfuls three or four times a day.

I will conclude and complete this study by giving below a resumé of treatment by Professor SIMPSON as given in the latest edition of Quain's Dictionary.

Treatment.—In instituting our treatment of leucorrhœa, it is of the first importance to have in view the constitutional condition of the patient; to use means to counteract any diathetic tendency—tuberculous, strumous or syphilitic; and to raise, as far as possible, the general standard of the patient's health by the administration of tonics and the enforcement of a suitable diet and regimen. It is partly in this way that a change of residence is often useful; and in making a change, it is well for the patient to go to some of the spas, such as Ems or Kissingen, the waters of which are helpful in reducing congestions and catarrhs of the pelvic viscera. In young women of relaxed habit of body, it may be enough to prescribe quinine and iron or arsenic, and the daily use of a cold sponge bath; and in infantile leucorrhœa cod-liver oil and iron should be administered.

In the great majority of cases of leucorrhœa, some kind of local treatment becomes an absolute necessity. Sometimes it is enough to pay strict attention to cleanliness, washing the pudendal surfaces with a soft sponge, or syringing the vaginal canal with tepid water; and even when astringent applications are to be made, the surface should first be subjected to a detergent stream of water. Where there is marked congestion of the uterus it is best to make the injections with hot water, and to keep the stream passing through the vagina for at least five minutes at a time; the immediate relaxation of the blood-vessels and hyperæmia being followed by contraction of their walls, which favours the cessation of the discharge. The astringents most serviceable for checking vulvar and vaginal leucorrhœas are alum, aluminated iron, acetate of lead, sulphate of copper, sulphate of zinc, borax, and infusions of oak bark, matioc, and other vegetables charged with tannin. They are best applied in the form of an injection with a Higginson's syringe, having a vaginal nozzle attached to it; or of a douche through a long India-rubber tube, with a stop cock for regulating the flow, fitted close to the vaginal nozzle, and the other extremity opening into a wide receptacle, or fitted to a filler into which the fluid is poured. Where there is a difficulty in using the injection, and where it is desirable to keep up a more prolonged application of the medicament, it may be introduced into the vagina in the form of pessaries made with cacao-butter or with gelatine. Topical applications to the canal of the cervix and cavity of the uterus ought always to be made through the speculum, and without such applications it is a hopeless task to undertake the cure of cervical leucorrhœa. Here, more concentrated or more powerful

astringents or secharotics become necessary. Nitrate of silver in the form of a stick of caustic is easily applied, but its repeated application may lead to necrosis. Zinc, alum dried, sulphate of zinc, sulphate of copper, perchloride of iron, or tannin may be introduced, in the form of rods or arrows made with starch and gum. If a uterine sound or stilette be dipped in water and a thin film of cotton wadding wrapped round the point to the length of about two inches, the adherent mucus can be cleared away, and the same or another sound mounted with wadding can be charged with burning nitric acid, the acid nitrate of mercury, strong carbolic acid, a solution of perchloride of iron, tincture of iodine, or iodised phenol, and carried through the speculum along the cervical canal. In intra-uterine leucorrhœa it becomes necessary to carry the application right up in the same way to the interior of the uterus. It is usually best to begin with one of the stronger liquids, apply it a few days after a menstrual period, and follow it up with applications of iodine. So long as the stilette or sound with the dry wadding passes easily through the os internum, it is usually necessary to continue from time to time the intra-uterine application.

Some remarks on the difference of treatment a hundred years ago and now, are necessary as a fitting conclusion to this article. It will be noticed that Professor CULLEN entirely depended on medicines given internally for its cure. He recommends some constitutional remedies as mineral waters, but it is evident that no vaginal examinations were resorted to. The astringents which he mentions are also internal agents. No douches, no astringent applications, no treatment of the os, or of the lining membrane of the uterus, no admonitions for cleanliness, and above all no antiseptics. And yet some old surgeons prefer the old times to the new.

—10:—

QUACKS AND QUACKERY.

BY GEO. E. CLAXTON, L.R.C.P. & S. Edin.

Officer on Plague Duty, Bandikui, Rajputana.

In all ages and amongst every nation on the face of the earth, quackery exists for two important reasons. First: The workings of the human body are so mysterious, the diseases to which it is subject so varied, and the causes underlying them so involved in obscurity that a variety of methods of treatment must necessarily exist. Secondly: The bulk of our community can be easily talked over by quacks, who are plausible, make pretensions to a world-wide knowledge of their subjects, and puff up their ignorance in a most bombastic manner. Just to illustrate how they can hold the attention of the public, I will cite a case in point. Many years ago, a quack was holding forth to a very large audience in the open air, in one of our largest English towns, and thereby secured a large and speedy sale for his nostrums; he was airing his knowledge on the anatomy of the human frame, but strangely transposing the important viscera, placing the heart on the right and the liver on the left side. Two medical men, who happened to be present, pointed out these errors; the quack seeing his predicament so carried the public by his eloquence as to completely turn the tables on the disciples of Galen, who had to fly for their lives from the an-

vagabond mob. *Mpet quacks* possess the gift of the gab, and they extensively advertise their methods and nostrums in the lay periodicals, and even medical men have been tricked by these. Not many years ago, a well thought-out and most cleverly-worded advertisement, setting forth in glowing colors the cures accomplished by a special electrical method, caught my eye as I was glancing over a periodical one day, the contained statements appeared so convincing and impressive that even a medical friend, whose opinion I sought, and who declared it to be a fraud, could not make me alter my views at the time, in fact I told him, after careful perusal, it could be nothing else but genuine. The method was tried, but to my utter disgust, proved a failure. This instance shows what intelligent advertising can, and does do, and if a medical man can be tricked, how very easy it is for anyone not versed in medical matters to be taken in.

It will be well to point out the differences between quacks and doctors.

(1). Quacks have had no special training in medicine; the little knowledge they possess is most fragmentary and superficial, and has probably been derived from some elementary treatise on the subject—hence quacks never like to discourse on medical topics with medical men; and if the subject is at all broached by the latter, get most irate as their ignorance is exposed. The fraternity on the other hand, ventilate their views at various society meetings; or consult with each other when a difficult case has to be treated, and so medical science is advanced. Quacks, in order to get known, have recourse to a variety of advertising dodges, whereas a medical man, depending on his own abilities and exertions, in process of time secures a large practice for himself, and gets firmly established in one place without resorting to advertising.

(2). The nostrums used by quacks are not only kept secret, but are vaunted as "panaceas" for all human ills. Medical men are perfectly aware that "a cure-all medicine" can never exist, and naturally regard these nostrums as being of no value whatever. No secret remedies are used by the profession, and the composition of our patent medicines are generally known. Moreover the materia medica and pharmacopoeias enlighten every member of the profession as to the nature, sources, and action of drugs. If any new remedies are introduced, their virtues, etc are clearly set forth in the medical periodicals for trial by other medics.

(3). Quacks, as a rule, like to be paid in advance, and their charges are most exorbitant. This is done with the object of quickly lining their pockets before the frauds, of which they themselves are perfectly cognizant, are detected. They can, without suffering any monetary loss, decamp at a moment's notice when they find a place gets too hot for them, and can start their fraudulent practices, perhaps under an assumed name, in some more congenial spot. A private practitioner, on the other hand, gets poorly, and sometimes not at all, paid for the conscientious performance of his duties, and I have known intelligent men to spend quite a small fortune on quacks who do no good, and withhold their fees, or otherwise grudgingly give them, to the family doctors who, in every way, try to benefit them, and bring all their science, skill, and when

needed, the opinion of another medical man, to bear on their case. What is the result? The quack often gets the praise, and the poor medico the blame if any untoward event takes place. If a poor patient comes to a quack for treatment, no interest is taken in his case, or else he is rudely repulsed, but if the same comes to a general practitioner, he is treated with kindness and compassion, and everything that can be done is accomplished, even though the hopes of remuneration be slight or nil. The former is a simple money-grubber, the latter a philanthropist, and in the treatment of destitute cases the cloven-hoof of the quack is seen at a glance.

Seeing such marked differences exist between doctors and quacks, can we wonder at the latter hating the former, or at their method of treatment based on empiricism being different to ours? It will be well to briefly consider the following questions:—Why do quacks exist? Why do folks patronise them? Do they do good in any diseases? Has the science of medicine at all benefited by quackery?

Why do quacks exist? As long as some diseases—instance cancer and phthisis—remain incurable in their advanced stages under our present methods of treatment, so long will the market be flooded with a host of quack remedies, professing to work magical cures in such cases, and quacks will abound and grow rich at the expense of the poor dupe, whom they most unmercifully fleece.

Why do folks patronise quacks? Some sufferers, after having given legitimate means a fair trial, cling, as does a drowning man to a straw, to the faintest hopes held out by any method which is advertised to do good in their particular ailments, and can we altogether blame them for doing this? They see the advertisement, may be in some paper, or a friend or relative directs their attention to it, and persuades them to give it a trial. Parents, too, in the case of their children, argue much as follows.—"Our children, when they advance in years, might probably cast a reproach on us; and say "why was not a method which held out even the faintest hopes of benefiting our case tried, when the means were so ready at hand?" To avoid such a reproach, many parents who are enlightened, resort to quacks.

Do quacks do any good in diseases? As a rule, quacks have in their employ paid accomplices, who swear that certain imaginary complaints from which they are or were suffering, have been benefited, or cured, in a most marvellous manner by the quack's remedies. Quacks too often exercise a mesmeric influence on their patients, and generally the nervous, hysterical, hypochondriac, and so-called paralysis, derive often permanent benefit from the means resorted to. Further, quacks by their plausible manner, often win the confidence of their patients, and the latter's strong faith so beneficially influences the mind, as to bring about a change for the better in many functional ailments from which they were probably suffering, but which quacks allege were cases of cure under their own hands. Lastly a quack, just like any layman might, by a sheer stroke of luck, hits accidentally upon a definite cure for a given ailment, and patients who are benefited thereby, naturally sound his praises far and wide.

Has the science of medicine at all benefited by quackery?

A study of the history of medicine teaches us that the most important advances have come from observation and experiment, and not from the dark ages superstition, authority, and dogmatism and fallacy. Many drugs which are recognized as powerful remedies in malaria, and even the Malay years used successfully. Vaccination, which is accepted as a safeguard against small-pox, was first in an empirical fashion long before Jenner made his important discovery. The ancient method of wound treatment was practiced for ages by Babylonian and Assyrian doctors; and even, in this country, many remedies employed by Indians are handed down from father to son as infallible for many generations, and their use is rigidly preserved in the family. Quackery or empiricism has baffled medical science in the past, but as our knowledge advances quackery will be forced to take a back seat, so to speak. I believe every disease under the sun has its appropriate remedy, and it remains for future generations of medics to discover these, and in so doing, deal quackery its death-blow.

A FEW REMARKS ON CHURCH HYGIENE.

By P. V. JERARDHAN Pillai, C. M. S.
Hospital Assistant, Singapore.

THE title of my paper may make many a devout Christian indignantly exclaim "Why is the church linked with hygiene in the one breath and what has hygiene, which is a purely State affair, to do with Holy Mother Church? And it may seem sacrilege for me to say that the Church must be purged of her sanitary sins, since made all the more heinous by traditional conservatism of certain rites and ceremonies that are void of common sense.

But built up as she is on sections drawn from all sorts and conditions of men and welded together in a Christian whole, the Church has unconsciously drifted into observances peculiar to each of its sections, but for which it has no divine authority. Many of these observances or rites are utterly opposed to sanitary requirements, and the sooner they are modified, if not altogether removed, the better for the entire Christian world and the millions of the unconverted, whom the Church hopes to embrace in her folds at some time or another.

I do not propose going through the entire category of her sanitary shortcomings, and for the present shall confine myself to two that demand immediate reform. The first of these, and a very grave one, is DISPOSAL OF THE DEAD BY CHRISTIANS.

I recollect having read in the *Indian Medical Record* a paragraph which I copied out in 1894, and a part of which runs:—"Death is merely a temporary lull of vitality in the transition stage on which all life is built, and itself is death in a number of ever-changing forms to perfect and develop which, cleanliness is essential. Absolute cleanliness is not only the first and greatest point on which Nature, God's handmaid, weds every joint of the marvellous chain of life, but is also an attribute of God Himself, but the generality of men either know a God or care for a God only as a God means a personal good to themselves," and in the illogical preservation of traditional customs little dream of the dangers they store up for their own posterity and contemporary men.

When following up the Christian tenet "Bury them decent and in decent shroud their bodies," they select their setting, who while living led a most useful life, plunge in a filthy, pestiferous and unhygienic coffin which they lower into a grave, dug in the very heart of a thickly populated area, and after the material substance of 'earth to earth, ashes to ashes, dust to dust' has settled them to their very souls they hurry away, leaving their bodies to the loathsome processes of slow decomposition rendered slower still by the encumbering earth. They either do not know or they forget that the feet of the body was held together by fluids, which are but liquefied gases, which during the process of resolution into simpler or elementary substances, are slowly given off and leak through the upper earth (see section 203 of *Disinfectants: their actions and uses*, published in 1894 in the *Indian Medical Record*) as vapors that increase sickness and mortality to a great extent, even though they may not be productive of any specific disease, or they may percolate towards the subsoil streams to pollute the water supply of some adjacent district.

And in this forgetfulness they build their churches in the centre of or on the very margin of their cemeteries, which they affectionately refer to as 'God's acre' and unwittingly put on acher which that acre variably becomes, by undermining the health of the worshippers in those churches, which may be further converted into 'chambers for dead people's gases' by the horrible practice of making the nave or aisles of some churches the last resting place (i.e., grave) of persons of note, and such priests or clergymen who were remarkable for their piety and other good qualities.

When the Rev H JONES of St. George in the East, London, could not dissuade the poor of his district from obtaining their drinking water from a pump inside the parish cemetery and argument seemed worse than useless, he discarded the pump with "DEAD MEN'S BROTH," which had the desired result, and from that time cholera and other infectious diseases that had hitherto devastated his parish began to disappear, while the poor enjoyed better health.

Again, with the population steadily increasing, there is a constant demand for building and cultivation sites which the graveyards unfortunately take up the room of needlessly. Needless I say, because burials could easily make way for cremation, which not only resolves the body more quickly into its elementary parts by doing in five or six hours what burial takes four to seven years to effect, but also completely does away with the nauseating noxious products of decomposition; as well as completely destroys the germs of many an infectious disease that burial only too surely spreads with greater virulence. Of course sentiment would rebel at the idea of burning a dearly loved relative, but sentiment is not always sane, and a little reflection will prove conclusively that it is better to reduce a dead relation to cleanly ashes that will harm nobody and can be heaped away in a small urn, than to consign him to the ground to be eaten by maggots and slowly rotting away; defile both air and water with disgusting loathsome smells. Sentiment like tradition dies hard; but cremation has gained in the thin edge of the wedge in Europe, and I think before long it will become general.

That man will be the Savior of his community who can convince both clergy and laity that in adhering to burial and one-eup-communion, they are deliberately sacrificing their health, by leaving undone those things that they ought to have done and doing those things that they ought not to have done.

The Sanskrit text describes the action of *moonseed* as laxative, stimulant, bitter tonic, puerine stimulant, antipyretic, anti-malarial, expectorant, aphrodisiac, anti-phlogistic, digestive, anthelmintic, diaphoretic, and antibilious—and, as such, I think the *Sphenanthus* ought to be given a prominent place in the British Pharmacopoeia.

A MIRROR OF PRACTICE

REPORT ADDRESS OF BRADY LAFAROTOMY

REPORT ADDRESS OF BRADY LAFAROTOMY

LAFAROTOMY, 1888

By JAMES E. WARD, M.D., F.R.C.S.

Physician of the Obstetrical Hospital of London.

Formerly Resident Surgeon at the Milan Hospital for Women and Children, Genoa, etc.

Mrs. W.—, 41st, with the English lady of 40 years, the mother of two children, the youngest 3 years old, a resident of Genoa for many years, had been under my treatment off and on for the past six years for recurrent ovarian and uterine occurring occasionally and irregularly at her menstrual periods, and due invariably to chills after bathing. Relief was always afforded by the use of local and internal sedatives and a few days' rest. Often she went for months without the slightest trouble, but I can recall two or three instances, when the inflammatory attacks in connection with the uterus and its appendages were so severe, as to be attended with serious constitutional disturbance, necessitating close and watchful medical attendance and rest in bed for two or three weeks.

The present illness supervened on a severe chill while bathing, and on the 5th January, I was called to see my patient, and found her suffering with high fever, great abdominal pain, and intense and persistent vomiting. Rest in bed, the application of counter-irritants and the use of sedatives and diaphoretics, caused a complete temporary subsidence of all febrile and inflammatory symptoms; and on the 9th January, she seemed to have recovered. Perfect rest for a week was enjoined. This advice was not followed; for on the 10th and 11th, the patient was about her domestic duties, and as a natural sequence, a relapse of pain and fever forced her to bed. Once more these symptoms subsided, and perfect rest was again insisted upon. On the 18th and 14th the advice was followed, but with a return of apparent health and freedom from pain, the busy toil of home work was again taken up in spite of serious warning against it.

On the 24th January, very acute tearing pain was felt in the left iliac region, attended by severe retching and vomiting, accompanied by faintness. When seen on this day, the abdomen was found tender to touch, more particularly the left side, and there was an ill-defined sense of tumefaction in the left iliac fossa. Simultaneously there was a free discharge of blood per vaginam, which lasted for four or five days. She was previously "unwell" on the 1st January, the present inflammatory trouble dating from a chill following a bath taken after that menstruation, just twenty-five days before. This strange combination of symptoms—the sudden tearing pain in the ovarian region, the faintness, the retching, the localized iliac tumefaction, the sanguineous vaginal flow—seemed to point to a possible ectopic gestation and rupture, but my suspicions were not strong in this direction, and I dismissed the probability of such a diagnosis from my mind. Subsequent draughts allayed the distressing vomiting, and the local symptoms were successfully combated by fomentations of the abdomen, the application of belladonna and the administration of opiates. While however, pain and

distress subsided for a few days, low as the temperature was without any appreciable fluctuation, ranging from 98° to 101° F. for days. On the 28th evening the severe upper abdominal and iliac pain, the 30th February vomiting ceased, and pain and tenderness returned in the now well-formed abdominal tumor. For three days everything ingested was ejected, and the patient had to be fed by rectal injections of soup, sugar water and brandy. She had become much lowered, and on the evening of 3rd February I detected distinct fluctuation in the swelling. On the 7th I asked Dr. WILLIAM COULTER to see the patient with me. He agreed with my opinion that there was a fluid collection in the broad ligament, and on my suggesting the tumor, I withdrew about six ounces of foul smelling, purid pus the same evening. Towards night the patient became much worse, the pain had subsided, but the vomiting was incessant and the temperature rose to 105° F. Next day the swelling re-appeared and became much more extensive, indicated a still larger accumulation of pus, while the pain and tenderness were intensified. Finding things getting so rapidly worse, I had another consultation with Dr. WILLIAM COULTER and Dr. JAMES GIBBY, on the 8th at noon, as I felt that nothing but a free opening into the abdomen would permit of a satisfactory removal of the putrescent fluid, and save the patient from the imminent risk, not only of a rupture of the abscess into the peritoneal cavity or the as probable sequence of fatal septic peritonitis, even without rupture. After careful examination into all the circumstances of the case, both these surgeons decided that laparotomy should be performed without delay. Accordingly at 3 P.M. on the 8th February, after the patient was carefully prepared for the operation, chloroform being administered by Dr. J. G. ANDERSON, with the able assistance of Drs. COULTER and GIBBY, I opened the abdomen in the median line by an incision from the umbilicus down to the pubes. On opening the peritoneum, the hand was passed into the abdominal cavity and a large fluctuant tumor, as big as an ordinary foetal head, was found filling the left iliac fossa and bulging upwards in contact with the pelvis. A few recent adhesions had formed to the adjoining tissues, but these instantly gave way as the finger came in contact with them. Careful manipulation revealed the fact that the tumor was a cystic abscess of the left broad ligament. Having regard to the purid contents of the cyst, the abdominal cavity was washed with gauze on all sides of the tumor to prevent the entrance of infective pus. The sac was now laid open, and quite a pint of very purid pus and sloughs pushed out. Having emptied and then irrigated the cyst cavity, it was now decided to shut out the peritoneal cavity from further continuous risk of infection by tying the open edges of the abscess walls to the margins of another abdominal incision in the iliac region, and thus providing separate drainage for the abscess. This incision was therefore made parallel to, but an inch and a half away from, the external cut, and to the apex of this wound the gaping walls of the abscess were sewn together. The purid green and smelly fluid, which oozed from the peritoneal cavity, it was constantly irrigated with boiled water at a temperature of about 105° F. Having fixed one drainage tube into the abscess, through the

the polypus. The polypus was found to have become considerably reduced in size and firmer in consistency, and on touch the offensive discharge was left.

Operation.—On the 30th of November, removal of the polypus by evulsion was decided upon, and the patient put under chloroform. It was found to be a solid tumour about the size of a hen's egg, and had extensive attachments to the left side of the roof of the pharynx. The attachments were found to be too firm and extensive to admit of removal with forceps.

On the 5th January last the patient was again put under chloroform. "Osteoplastic section of superior maxilla" was performed after preliminary laryngotomy. The upper lip was divided in the median line and then by means of a chisel the superior maxilla was divided through the palate process and above the alveolar border, the bone was then readily dislocated outwards and the pharynx exposed. As the growth had extensive attachments and was very fibrous in its nature, it was removed from its base partly, by means of the fingers and partly by scissors; the hæmorrhage was free but was controlled by plugging. The bones were then sutured together by means of catgut suture after drilling, and the skin incision united in the ordinary way."

After treatment.—He was ordered three ounces of rum in 24 hours. To be fed with milk every fourth hour with a pharyngeal tube. On the fourth day of operation the plug was removed and boracic acid irrigation ordered for the nares. On the sixth day the stitches were removed; and on the eleventh day the patient was discharged; the superior maxilla had fairly united and both the nostrils were quite free, so that he was now able to breathe through the nares. On microscopic examination, the growth was found to be a *fibro-sarcoma*.

Remarks.—This case illustrates in a remarkable way the achievements of modern surgery. The patient, when admitted, was a most wretched specimen of suffering humanity whose very existence was a burden to himself. The exposure of the pharynx by this method was sufficient without the least possibility of any deformity resulting after the operation. The bleeding was terrific, and the surgeon had to fish out the tumour with his fingers from the pool of blood which filled the nasal and buccal cavities throughout the operation in spite of constant sponging; the prognosis varies not only with the duration and extent of disease and the condition of the patient, but also with the skill of the surgeon under whose charge he happens to be.

CASE OF SEVERE HOMICIDAL OUT-THROAT: VERTICALLY DESTROYING ENTIRE LARYNX AND A PORTION OF TRACHEA: RECOVERY.

BY RAN LALL SINGH, C.M.S.

Camp Line Loo, Chinese Frontier Commission.

KHASOON, a Kharang, Hindu male, cooly by profession, was brought one day by the police to the Civil Hospital, Monywa, Upper Burma, when I was immediately sent for. On my arrival, I found the patient sitting on the

floor trying to describe how the incident took place. I was surprised to see the condition of his throat. He was unable to speak, emitting only a sort of low husky noise. The police gave information that they had found the man lying near a Buddhist monastery at about 11 A.M. quite prostrate, with his clothes and bedding perfectly saturated with blood. They wanted to run him in for attempt at suicide. This, however, was quite opposed to reason, the nature of the wound being such, that no would-be suicide, however determined, could possibly have cut his throat to such an extent as to slice off the entire larynx with the exception of the upper portion of the epiglottis, the upper third of the trachea was also injured. The cut extended $2\frac{1}{2}$ inches across the throat, was 2 inches broad and penetrated to the posterior wall of the larynx and trachea. The wonder is that the man did not bleed to death.

Treatment.—The wound being first cleaned with an antiseptic lotion, the flap was stitched to the right margin of the wound, which was then dusted with iodoform and dressed with dry lint, a bandage being so applied as to keep the head down. He was then given some milk to drink, which however he could not manage to take, as the act of swallowing brought on a fit of coughing, the greater quantity of milk escaping through the wound, a few drops also fell into the air tube. So we had to feed him by enemata of milk, chicken soup, eggs and brandy for seven days, after which he was able to swallow liquid nourishment.

On the fourth day after his admission, the suture gave way and it was found impossible to stitch it again, the flap having contracted considerably, so the wound was kept partially open and a tracheotomy tube was inserted and kept in for a few days. The wound healed slowly but surely, and in six weeks' time was perfectly well.

FATAL UNCONTROLLABLE HÆMATEMESIS.

BY ASSISTANT SURGEON JAIKISHAN DASS,
Sonepat.

TEIKHA, a Hindoo male, æt. 32 years, was seen the day previous at about 3 P.M. He had had a cool bath in the morning and a full meal for breakfast at about 11 A.M., consisting of *bajra* (millet grain) cooked in the syrup of *Gur* (jaggery). He had vomited four pounds of dark colored blood at about 12 noon. This had of course alarmed him greatly as blood spitting often does, and when seen by me, he had a very anxious look. He was treated with acid gallic, ext. of ergot, hemoline, &c., &c., but without any benefit. No ice being available, cold was applied to the pit of the stomach in the shape of cloths soaked in a lotion of nitre, salt and chloride of ammonium, but this had no effect either. The vomiting recurred and quantities of blood were brought up each time. The man died at about 1 A.M., the intellect remaining clear to the last. There was no history or signs of cancer or ulcer of the stomach nor any other appreciable cause.

Indian Medical Record.

15th March 1895.

CRIMINAL RESPONSIBILITY OF THE INSANE IN INDIA AND ENGLAND.

The question of the criminal responsibility of the insane is again prominently before the public, owing to the result of the trial of *ANANDA*, the murderer of the well-known actor, *TERRELL*. In this case, it will be recollected, that the jury found the prisoner guilty of murder; they also found that he was responsible for the nature of his action; but on the medical evidence they found him insane.

This verdict has caused considerable dissatisfaction, and is leading to a general discussion of the whole question of the criminal responsibility of the insane which, as is well-known, is a matter of considerable controversy between the legal and medical professions. In India the Penal Code endeavours to restrict the question as much as possible by prescribing that "nothing is an offence which is done by a person who, at the time of doing it, by reason of unsoundness of mind, is incapable of knowing the nature of act, or that he is doing what is either wrong or contrary to law." At first sight this limitation of insane irresponsibility seems to be amply sufficient, but it by no means provides for even the principal phases of insanity; and, judged strictly by the test of the Indian Penal Code, many a lunatic would have to be condemned.

In England the law is more elastic on this point; but even here it is admitted that the matter is in a very unsatisfactory condition, so much so that a learned judge of great experience, Lord BRANWELL, declared before a Committee, that "the present law lays down such a definition of madness that nobody is hardly ever really mad enough to be within it." And if this can be said of the English Law, which is more comprehensive on the subject than the Indian Penal Code, what must be thought of the latter?

The whole difficulty arises from the necessity of distinctly defining the extent to which insane people can be held to be responsible for their actions. The medical notions on the point differ very considerably from legal conceptions. Some medical authorities hold that a person in any way insane should be irresponsible before the law, these urge that a brain which is morbidly unbalanced, even to a slight degree, cannot be relied on to take sound and reasonable views of matters of every-day occurrence. Others make the loss of self-control the test of irresponsibility, but it is extremely difficult, if not impossible, to say definitely when loss of self-control commences.

The English judges are by no means prepared to go as far as the doctors, but they have experienced much difficulty in precisely defining the limits of insane irresponsibility. The same test as is prescribed by the Indian Penal Code of course holds good in England, but the

Judge has given evidence that they have held that those who commit crimes under the irresistible impulse of some insane delusion are irresponsible, though they are able to discriminate as to the nature of their deeds. For example, a man may be perfectly able to recognise that he is committing the crime of murder and is thus grievously offending the law; nevertheless his mind may be so perverted that he is unable to resist some insane delusion, which impels him to commit the crime, such a person would escape the gallows in England; but in India, if the law be strictly interpreted, his case could not be included in the section of the Penal Code above quoted. The practice of any large lunatic asylum furnishes numerous instances of lunatics who are perfectly able to discriminate as to the nature of their actions, but who are suffering from some insane delusion. Not a few reason insanely from sane premises; others reason sanely from insane premises, while others again reason insanely from insane premises. Most of these would, strictly speaking, be held responsible to the law for their actions. For instance a man may easily be seized with the delusion that he is a special apostle of some particular religion, and that he is therefore called upon to smite every unbeliever. Such a person would, as a rule, be able to thoroughly recognise that he was committing a crime in striking down an unbeliever, nevertheless he would be impelled to the commission of that crime by the peculiar delusion which has taken possession of him. The French Law prescribes a better limitation than either the Indian or English Law; for it provides that "there is no crime or misdemeanour when the accused was in a state of dementia at the time of the commission of the act, or when he was under the control of a force he was not able to resist."

In England there are some notable leading cases with regard to pleas of insanity; but unfortunately they do not serve to remove the confusion investing the subject. About four years ago, a young gentleman at Leamington shot his father dead under the impulse of a delusion that the latter was systematically persecuting him. Mr. Justice WRIGHT, who tried the prisoner, told the jury that his responsibility to the law ceased if it was found that he had been acting under the impulse of a delusion, even if he was able to discriminate as to the nature of his crime. The jury returned a verdict in accordance with the learned Judge's direction. In another recent case, Mr. Justice BLACKBURN seems to have gone even further, and before a Select Committee he stated with reference, to this case:—"The prisoner clearly knew right from wrong and knew the character of her act, and was quite aware of what she had done, but I felt it impossible to say that she should be punished. I told the Jury that there were exceptional cases." In the case of *OXFORD*, *et al*, 17, who fired two shots at the Queen in 1840, Lord Chief Justice DENHAM, in his charge to the Jury, remarked with reference to the plea of insanity set up on behalf of the prisoner:—"He might be labouring perhaps under a delusion which affected every part of his conduct, and was not directed to one object alone. If that were the case, and if the disease affected him at the time the act was committed, then he could not be held accountable for it. One cannot say what a person under such a delusion may do; and the motive in that case would not be apparent." The Jury returned a verdict of "not guilty on the ground

At the trial the defense put in medical evidence to show that the prisoner had contracted the crime under the influence of an irresistible physical impulse, according to which he was required to "make away with the Professor for political reasons. In this case also the Jury brought in a verdict of "not guilty on the ground of insanity" or as the southern tradition run (according to a recent Act) "guilty but insane." According to the strict interpretation of the Indian Penal Code, all these prisoners would have experienced difficulty in escaping the gallows.

It is to be hoped that the present discussion of the question of Insane Responsibility will result in some reasonable extensions of the limits allowed by the law, particularly in this country.

A HOUSE DIVIDED AGAINST ITSELF A LESSON TO THE MEDICAL PROFESSION.

The evil growth of "Hospital Abuse," which we discussed in our last issue, owes its monstrous origin and abnormal dimensions entirely to the fact that in the ranks of the medical profession there is no such thing as cohesion; no such thing as a UNION.

In this respect, the profession is in a pitiable plight and lies naked and defenceless before the attacks of those who desire to prey upon it.

It would be idle here to enter into the abstract question, if there is any fundamental and essential attribute of the profession of medicine that is incompatible with the unity of its members; the fact that unity does not exist is enough for us, and this fact is only too generally and notoriously admitted.

Some may seek for an explanation in high ideals, and a lofty sense of duty; the loud-voiced majority will find it at a lower moral elevation, in envy and selfishness.

We may remark that the Church, whose ideals and aspirations are sufficiently lofty, does not let these qualities interfere with the proper governing of her mundane affairs; and though the domain of religion presents many openings for the development and expression of individual opinions, she visits such breaches of discipline with her severest displeasure, and she is justly as sensitive and intolerant of outside criticism as of internal contumacy.

The medical profession has no wise governing body, which it can look up to and respect, and which, while punishing faults, has the will and power to further the interests of its members, and protect them from injury.

For such a body we must look to the future.

In the meantime all is discord and dissension. What is the attitude of one medical man to another? An American journal describes it as follows:

"Suspicion took the place of confidence, and envy that of admiration for deserved success. Physicians began to snarl at each other before their patients; they began to imitate the acts of small shop-keepers and to underbid and to upbraid their brethren. Some even went so far as to do to accept medical charity in public faith-

fulness, shamefully neglecting their duties, and leaving their patients thus deprived of necessary medical aid. All the words of hostility and ill-will that our patients, and thus hold themselves against their professional brethren eager to attack them on any terms. What, then, has become of the sympathy, the regard, which we even yet boast loudly and do not exhibit? Do we not know and daily feel to our shame that, with our loss of mutual self-respect and confidence, the public also have lost almost the semblance of respect for us collectively?"

Can we say that this is exaggerated, or even that it is exaggerated?

It is the spirit engrafted from our student days. When we sit at the feet of our lecturers, who are freely discloses for our edification, and their own adulation, the little mistakes of their colleagues.

It is the wholesome sense of discipline, which exists in the Church and in the Law that is so sadly lacking in the Medical Profession, a certain healthy feeling of restraint is good for us all, and absolutely necessary for many.

There is probably no more free and untrammelled agent than the young practitioner just let loose upon the public, the Body responsible for his education has pocketed his fee, its duty ends there, in his future career and conduct it takes no concern.

The evils that may result from this unlimited freedom, and the unscrupulous and licentious use to which it may be put, are probably more in evidence in the United States than anywhere else, and Dr. J. HILLIS of New York, has described them in an elaborate and interesting paper in the *Medical Record*, of Dr. "YOUNGBLOOD," the type of this species he says—

"Now Dr. YOUNGBLOOD cares not a mill for the etiquette of his profession, it has no concern for him. At present he is interested only in himself, and must and will build up his practice, even though the heavens fall and the earth trembles under his feet. Now to accomplish his purpose he will break down all the barriers that have hedged in the traditions of an ancient and honorable calling. He flings etiquette out of the window."

"Dr. YOUNGBLOOD is the incarnation of the pernicious activity and commonplace audacity with which the medical profession is to-day honeycombed, undermined, and disgraced. The YOUNGBLOODS have made our calling the jest of the people, they have so injected the element of fakir and three-card-monte war into the current of medical thought, that the honest and intelligent practitioner blushes while contemplating the future of his profession. These YOUNGBLOODS have divided, demoralized, and prostituted our profession to their own selfish ends, so that it is an easy prey for the wily hospital governor to feed on, or the philosopher to teach a truth or point a moral with."

It is evident then that the medical profession has its enemies within as well as without, and all the result of its wretched unorganized and unorganized state.

The question may well be asked, is there any remedy? What steps should be taken? Nay, rather what have they not tried?

At the present day, the profession presents a body of men inferior to none in medical attainments, energy and the able and conscientious performance of duty; while

cautious reflections upon administrative details, every hospital in the metropolis receiving these unsolicited attentions.

In order to do this he had to employ reporters to work for him.

A few extracts from these reports up to the year 1838 will enable an estimate of their value to be arrived at.

In March 1825, a man was admitted to St. George's Hospital suffering from pneumonia. He was bled in the arm by the dresser, and during the little operation the brachial artery was wounded.

The man was placed under one of the surgeons who, on consultation with the physician, considered that the pulmonary trouble was too severe to warrant him in disturbing the patient by tying the brachial artery—obviously the only safe course to pursue under the unfortunate circumstances.

A tight bandage was placed upon the arm above the wound instead of a ligature upon the vessel. The bandage remained three days untouched, when the circulation having been occluded mortification set in, and the patient died.

A coroner's jury brought in a verdict that the man died from the accidental opening of an artery in the arm, and from the want of proper attention.

Four months later a still worse case of malpraxis occurred at the same hospital.

A man was admitted to the accident ward whose right knee had been cut by a broken bottle, the house surgeon thought that an artery had been severed and applied a tight bandage.

The patient was under the care of the same surgeon, who did not, as it afterwards transpired, examine the knee himself, but left the bandages undisturbed for five days, when the limb was found in a terrible condition. The man died and the verdict of the coroner's jury was that "the deceased received a cut on the knee by accident, and from the effects of improper surgical treatment and neglect his death was produced."

Upon these cases the *Lancet* made exceedingly severe comments and freely mentioned the names of all concerned.

Almost at the same time it was noted that in the Middlesex Hospital not more than one patient had recovered from an operation for strangulated hernia during two years, and several cases of malpraxis at Guy's Hospital and St. Thomas' were detailed at length.

"Nothing is more easy," he wrote at this time, "than to show that our hospital system is all wrong, the men who are elected to the vacant posts are men with a good city connection.....and ignorant pretenders exclude men of sound talent.

On 29th March 1838, there appeared the report of a case which led to the most sensational lawsuit that WAKLEY was ever engaged in. The case of BRANSHY COOPER, v. WAKLEY. It contained the most outspoken denunciation of a piece of hospital malpraxis possible to conceive. The plaintiff, Mr. BRANSHY COOPER, was infamously called a murderer, and in a leading article the defendant justified the accuracy of his report, and his right and duty to publish it.

The operation in question took place at Guy's Hospital, and was a lithotomy performed by Mr. BRANSHY COOPER,

then a Surgeon to the institution of three years' standing. The patient was a strong, middle-aged countryman, for whom the procedure of cutting for stone, should not under ordinary circumstances, have had any particularly grave risk.

The account given was short but horrible, and the horror was accentuated by its dramatic form. It was divided into Act I and Act II, the first act with the preliminary steps, which took 30 minutes and indicated that the original incision having been wrongly made, the operator lost the proper appreciation of the anatomical geography, and attempted violently to effect a passage with his forceps where no incision had cleared the way.

The second act to have lasted half an hour, accused the Surgeon of having hopelessly lost his head. It described him as calling for all forms of instruments, asking for the assistance of his colleagues and even of his dresser, and complaining in front of the patient, of course un-anesthetised of his utter inability to understand the cause of his own terrible failure to extract the stone.

No more terrible picture of incompetency, of want of skill, want of nerve, and want of heart could be imagined than the picture that was drawn. It was further insinuated that BRANSHY COOPER owed his position on the staff entirely to the fact of his being Sir ASTLEY COOPER's nephew.

He had no alternative but to bring an action for libel against WAKLEY.

This case excited the greatest popular interest; the court and all passages leading to it were crowded, and it was as much as the counsel, jury and witnesses could do to obtain an entrance.

WAKLEY defended himself, aided by Mr. BAUGHMAN, and was opposed by Sir JAMES SOARLETT.

It is not necessary to enter into the details of the trial. After an absence of two hours the jury returned a verdict for the plaintiff with £100 damages, this was equivalent to a victory for both sides; the verdict told its own tale. Most certainly the jury believed WAKLEY's main statement that the plaintiff had been guilty of malpraxis, on no other ground could they have let him off so cheaply, for of the £2,000 claimed only £100 were awarded.

This trial increased the hostility of the hospital officials against WAKLEY, and at no time in his career had he such bitter and organised opposition to meet as immediately after this sensational trial. His reporters were expelled from the learned societies, he himself was excluded from three or four of the largest metropolitan hospitals; while, on the other hand, every facility was given to the other medical papers of the day.

This galled WAKLEY and his feelings found vent in savage criticism of his contemporaries.

They in their turn wrote in unspeakable terms of him, and the recriminatory passages, certain of which will be quoted in connection with WAKLEY's actions against Dr. MACLEOD, the Editor of the *Medical and Physical Journal*, and Dr. JAMES JOHNSON, form amazing reading for these latter days.

By this time, however, WAKLEY had behind him a strong following, and a magnificently attended public meeting was held on the Tuesday following the verdict, at which a series of resolutions of a flattering nature were passed, and a subscription raised to pay all his expenses in the trial which amounted to £200 odd.

It is related that in after years a formal reconciliation took place between WAKLEY and BRANSHY COOPER.

Medical Department, Surgeon-General LAWRENCE, eagerly awaiting at Headquarters for the expected intelligence, and getting more and more uneasy and surprised as day after day passed and the news came not.

At length, feeling no doubt that something had gone wrong, he despatched his personal assistant, Mr. H. TRIPP, to the Sholapur frontier; the step was taken not a moment too soon.

Mr. TRIPP proceeded to Itkal, close to Naldurg, and in the Naldurg district, the chief authority of which was invested in Mr. SHAM ANNA HANNAK with the title of "the first Taluqdar," Zillah Naldurg, on the 18th January 1898, he reported to this official that there were three badly infected villages, 2 miles, 9 miles, and 18 miles respectively from Itkal. The first, Keshagaon, had 21 cases and 18 deaths; the second, Dhodri, 55 cases and 48 deaths; the third, Woolagaon, 19 cases and 14 deaths.

"It is greatly to be regretted," he says in his report to the Taluqdar, that you have not been able to visit Itkal in person, as there are so many pressing and important matters to be undertaken, which only yourself, as the head of the district, can authorise and sanction." "I beg to request you will, if it be at all possible, come, without loss of time, to Itkal."

The Taluqdar, however, preferred touring in a more salubrious part of his district, and to get him to Itkal was beyond the power of man.

The next day TRIPP added another to his list of infected villages, Sarrati, 2 miles from Keshagaon, with 5 cases and 2 deaths, and reports to the Medical Director that with the Taluqdar sitting in camp 60 miles away, absolutely nothing can be done.

On the 19th January LAWRENCE also received reports saying that plague has crossed the frontier from Ahmednagar. Two cases had occurred at Davalgaon and one at Peepia, and two deaths at Ambora.

Some of these cases had occurred as far back as December 1897, but the Tansedar had suppressed the information.

Plague having crossed the frontier and having become indigenous in the Nizam's Dominions, the next thing to do was to take steps to deal with it as effectually as possible.

Two things were urgent: to prevent its further spread and to discover the exact amount of mischief already done.

On 25th January, Surgeon-Colonel LAWRENCE writes to Mr. A. H. STREVEN (The Secretary, Chudarghat Municipality) notifying to him that he has been appointed "Plague Commissioner in the districts of the Dominions off the railway, comprised roughly, in the tract of country between Gulburga and Aurangabad." This area from the adjacent frontier towards Hyderabad city is to be styled the "infected districts."

We find Mr. STREVEN's duties clearly defined, with the machinery for carrying them out, and the methods to be adopted in infected places. "You will be invested," the letter says, "with the powers of a first-class magistrate during the period you are employed on plague duty, in order to enable you to enforce the plague rules of Government. On the other hand, all district officials and all special officers whether civil or military, as well as troops and police will be directed by Government to implicitly obey your orders."

It is a satisfactory proof of the good understanding existing between the Nizam's Government and their Medical Director, that all Surgeon-Colonel LAWRENCE's recommendations were approved in toto, and promptly promulgated in orders.

Surgeon-Colonel LAWRENCE was appointed Plague Commissioner. Mr. A. H. STREVEN and Mr. FELLOWS, Deputy Plague Commissioners; the former was to guard the Railway lines; a full detail of the troops available for plague duty was submitted by the Chief of the Staff.

The campaign then commenced in earnest.

In the meantime TRIPP had not been idle. By the 29th January he has discovered three more infected villages—Kadky, Karamba—which had given shelter to 753 Sholapur refugees, had 82 cases and 12 deaths, Nanuj with 239 refugees had 4 cases and 2 deaths.

The first Taluqdar had got as far as Tuljapur, at this safe distance he delivered an exhilarating address calling upon everyone to give all the aid in his power to check the spread of plague; the address was received with acclamation, and three Hindu gentlemen were so overcome by the interest shown in their welfare by the Taluqdar, that they addressed the meeting on the subject, and enthusiastically lauded him "for coming all the way from Parenda at such personal inconvenience."

When, however, TRIPP suggested that he should come as far as Itkal to meet the Deputy Commissioner, Mr. FELLOWS, he found he had very important business elsewhere, and could not be moved.

This gentleman was relieved from the uncongenial sphere of plague duty by order of the Government on 1st Feb.

The following interesting paragraph occurs in TRIPP's letter:—

"Tambulwadi was visited by plague upwards of a month ago, but the inhabitants, with great promptitude, vacated the village of their own accord. They cleared their village afterwards and were permitted to re-occupy it about ten days ago by Hakim NUSBAWANI P. CHENOI. The people acted somewhat hastily in returning so soon to their houses, but, up till now, all is well with them."

From this it appears that this village was re-occupied about the 19th January after being evacuated for 20 days or so. It remained plague-free from that time, up to the middle of February at any rate. We have no later information.

On the 30th January, LAWRENCE reports to the Government, summing up the situation:—

"The great danger," he says, "is that places may have become infected, that we do not yet know of between Umergi and Bidar on the one hand, and Hyderabad on the other." He recommends that the three main roads from Hyderabad city towards the Sholapur side be patrolled, and all the surrounding villages searched, and that a "patrolled line" be established to guard the city, the situation of the line to be defined when the plague has been accurately mapped out.

The city of Hyderabad is to be placed in a state of defence, the Municipalities are to be sub-divided, and a responsible officer placed over each sub-division. Three camps are to be constructed: one for the isolation of the sick, one for the segregation of suspected persons, the

third for the segregation of healthy subjects from infected areas.

STEVENS had gone to Sholapur to interview the Collector, and the necessary matters were arranged there. He soon comes to the conclusion that it is impossible to prevent refugees crossing the border, that search parties are the only means of discovering the places infected.

In Sholapur they are spending Rs. 1,000 a day on disinfectants. LAWRENCE will have none of them; he resorts to the more effective method of fire.

His rules are as follows, after complete evacuation of the infected village:—

(a) Complete isolation of the sick and their attendants.

(b) Segregation of the healthy, among whom there may be persons who have contracted infection without knowing it, until the incubation period is over. The incubation period lasts ten days.

(c) Disinfection by means of, (1) the entire destruction by fire of infected materials such as the dug up surfaces of the floors, and the scraped surfaces of the walls of houses, and of all excreta; (2) destruction of the infection which is carried about in materials, such as clothing, by heat in the form of boiling water, and by prolonged exposure to sunlight and air, and (3) destruction of infection by drenching with water. Special stress is laid on the digging up and burning of floors.

(d) Chemical disinfectants are useless and must not be employed."

STEVENS having seen enough at Sholapur, sets to work with a will, and considering the obstruction and opposition, his rapidity of action is wonderful. He is evidently the right man for the work. On 1st February, he reports the evacuation of the following villages. Warlagaon, Kihki, Dhotri, Karamba and Nanuj. On the 4th, he reports the evacuation of Sarrati and Keshagaon; he found cavalry search parties under ARSUN DOWLAH most useful.

Bad news comes in from Ganjoti and Umerghi, nearer to Hyderabad, and STEVENS hurries off, the journey was made under great difficulties, bad roads, no bridges and no means of conveyance. He arrived at Ganjoti to find "the people panic stricken, and dying like rotten sheep in all the houses;" the death-rate was 15 a day, every obstruction was put in his way, as the people considered him an interloper, and that only Paigah officials should do the work in the Paigah illacka. He took the high hand however, and with much reluctance they consented to evacuate in 24 hours.

At Umerghi the difficulties were even greater; the people maintained that there was no sickness; here the police Amin of Ganjoti turned out an unexpected trump, with his help, he inspected some of the houses. He describes the result as follows:—

"The first house we went into was a big two-storied peeco house which was apparently deserted, although clothes and brass pots were lying about and piles of bags of grain etc. I went all over the house and looked in all the rooms and found not a living creature. I must say I thought it rather strange that neither the Patel nor the Amin, nor in fact any one came into the house with me, and I was just going out when I heard a sort of hissing sound in one of the small side rooms. It was quite dark, without wind, the only light entering from a very small

door, but I crept in and there was a young bunnia woman nearly nude and at her last gasp. It made me feel sick; so, to relieve my feelings, I ran outside and seized the Patel by the collar of his neck and dragged him in, to see and insisted on the police Amin and about half a dozen others coming in too, which they did very unwillingly, having first tied their clothes over their mouths. It was a lucky find, as I became master of the situation at once. The next house contained a young man, delirious and dying. In the third house we found a young sowcar who had a large suppurating bubo in his neck. I ordered the village to be cleared out next day, which it was."

At Ganjoti, there had been about 125 deaths and about 150 at Umerghi, Terrori, a village in the neighbourhood, was also found to be infected.

These three places were all evacuated by the 11th February. Sir KHOSHED JAH, and ARSUN DOWLAH proved excellent friends and not only promised, but gave every assistance in their power by means of the troops at their disposal. As for the Talukdars and Tehsildars, he did not even see them, while the revenue authorities gave no assistance, and he was much handicapped for supplies and tools.

In STEVENS' opinion, the whole country for 30 miles round Ganjoti was infected, and grave fears were entertained for Kallianse, which has a population of 15,000, these happily proved unfounded.

On the 22nd February, LAWRENCE, having completed all arrangements at Head-Quarters, seized the opportunity and started for a tour of inspection in the infected districts. Thus, we see, these four Europeans struggling, and struggling successfully, against the plague, combined with native obstruction and opposition in these vast dominions, and the credit due to them is all the greater that they have so far done the work without calling for any extraneous assistance.

There is one further and important point which we have reserved and which demands attention.

STEVENS learned at Sholapur that "the Collector (WEIR) and all the other plague officers I met look upon a recurrence as soon as the towns and villages are re-occupied as almost a certainty, and they are making all their arrangements accordingly and erecting substantial sheds, hospitals, and segregation camps for the rainy season when the present grass and mat structures will be useless. Putting existing circumstances on one side, if a recurrence occurs at Sholapur all our troubles will recommence as at present, roughly speaking, there are 50,000 refugees from British territory living in the Nizam's country. These refugees are now slowly commencing to return to their own villages, partly because there is little or no plague in Sholapur at present, and partly because now that we are evacuating our infected villages, they are put to inconvenience and are worse off than if they had remained in their own villages. When plague breaks out again in Sholapur, there will doubtless be another general exodus into the Nizam's country."

This news did not at all please LAWRENCE; the hardship of keeping the villagers out in the field until the rains is very obvious, besides a recurrence after such a prolonged evacuation would simply amount to a conviction of failure.

In case of any epidemic, the city is divided into districts, each of which is under the supervision of a sanitary inspector. In case of plague over the neighbouring districts, the district is a very obvious one.

We understand that at present all the ways into Highland are patrolled, and that there is a "cordon" round the city. People proceeding themselves at the gates are detained in an observation camp if they have fever; if they are free from fever, they get papers, and on reaching the station are admitted into the city, and their destination noted, so that they can be kept under observation for 14 days. There is, then, no such thing as quarantine in Munich.

THE HISTORY OF TYPHOID FEVER IN MUNICH.

The *Quart* paper under the heading which appears in the *Landes*, 5th February 1904, comes at a very opportune time, and is full of interest and important suggestions for this country. We are therefore glad to recapitulate its most striking points at some length.

"The history of typhoid fever in Munich," he says, "during the last 50 years is for many reasons of the greatest interest. The extraordinary prevalence of the disease in the city during the sixth, seventh, and eighth decades of this century; and its extraordinary reduction since 1860 probably present a unique record in epidemiological history. Special interest is added to this record by the fact that Professor Von POTTENKOPF, and his school concluded long ago that no connection could be traced between the incidence of typhoid fever and the distribution of drinking water in the city, but that a very distinct causal relation was indicated between the incidence of typhoid fever and the conditions of the soil."

Munich presents particular facilities for an investigation of this kind, as all the necessary data have been carefully recorded during the last forty years.

The mean annual mortality from typhoid fever per 100,000 inhabitants in Munich was 202.4 in the sixth decade; 147.8 in the seventh decade; 118.7 in the eighth decade; 16.0 in the ninth decade; and 5.6 in the period 1891-1900, the mean annual typhoid mortality of the ninth decade was less than one-seventh of what it was in the eighth decade. Epidemics which were frequent before 1860 have ceased since.

Since 1890 the annual death-rate from typhoid fever in England and Wales has been reduced to one-half, in Munich it has been reduced twenty-fold.

Satisfactory evidence is produced to show that this extraordinary reduction has not been miscalculated or exaggerated, and a sketch and description of Munich and its surroundings is given.

It is situated on a gravel bed from 10 to 50 feet in thickness, sloping to the north with a layer of impermeable soil below, over which the sub-soil water flows.

Drainage of Munich during the sixteenth century.

From time immemorial until 1855 nearly all excreta were deposited in privies and cesspits, so constructed that their liquid contents drained away into the porous soil. By similar arrangements the slops and liquid refuse from the houses were allowed to soak away into the soil. In 1855 an order was issued that all cesspits in the city

should be made watertight. The result was that the drainage of these cesspits and privies was carried out by the municipal authorities. This work could only be carried out by digging the cesspits and privies out from houses, the walls with suspended slabs to the soil until 1878; and then, when digging up to the present time they have gradually been replaced by the soil and conveyed into the city sewers. Since 1855 only the old city and some of the suburbs on the right of the Isar appear to have had sewers. Before that time the systematic drainage of these parts surrounding the old city was begun and carried on until 1878. From then from 1881 up to the present time the sewerage and house-drainage of the rapidly growing city have been gradually improved. Since 1890 the old watertight cesspits have been rapidly replaced by sewers.

Water-supplies of Munich from 1861 to 1900.

During this period and from the beginning of the century the city was supplied with drinking water entirely from the sub-soil water; the houses were more or less surrounded by houses and other buildings and subject to constant pollution, and all the analyses showed signs of organic pollution.

In 1865 a considerable and pure water supply (Pottenkofer supply), was added to the southern and western part of the city. In 1893 the present excellent water supply (Highland) was introduced, which has now supplanted nearly all the old supplies.

POTTENKOPF'S RESEARCHES.

Beginning in 1854 as a believer in the constant convection of typhoid fever and cholera by the drinking-water, POTTENKOPF first turned his attention to the distribution of cholera during the great epidemic of that year. He expected to find exceptional opportunities for proving the truth of the drinking-water theory owing to the number and peculiar distribution of the many different water-supplies in the city. He ascertained the water-supply of each single house by means of the Royal and Municipal Water Rates and by personal inspection; but in all cases his expectations were disappointed and he could find no connection, local or temporal, between the water-distribution and the cholera outbreaks. He made similar investigations with regard to the typhoid fever incidence in Munich and the distribution of the different water-supplies and always with similar results. He could never trace any of the local outbreaks which frequently occurred to any of the many separate water-supplies. Finally, he was convinced that in Munich there was not the slightest connexion between the drinking water and the typhoid fever. He next turned his attention to the conditions of the soil. In 1858 his observations of the height of the sub-soil water in various parts of the city were begun; these have been continued up to the present time.

These show that there is a very distinct correspondence—

(a) between the rise of the sub-soil water and the fall of the typhoid fever prevalence; and also (b) between the fall of the sub-soil water and the rise of the typhoid fever prevalence, such the time when the epidemic was begun to subside.

Thus a rapid fall in the sub-soil water is followed by a great outbreak of typhoid fever, as shown especially in

the epidemic of 1871-1872, the year of the epidemic of typhoid fever in Munich was 1871. In 1871 the epidemic of typhoid fever was at a high level, the epidemic of typhoid fever was at its lowest—i.e. during the years 1880 and 1881 and 1882. During the winter of 1871, 1872 and 1873 the rapid fall of the sub-soil water is followed by a series of epidemics. After 1873 the sub-soil water appears to be followed by a series of irregular attempts at epidemics until 1881, after which year they ceased altogether.

The constant relation between the variations of the level of the sub-soil water and the variations in the typhoid fever mortality is confirmed in a remarkable manner by Dr. POAR's observations on the typhoid fever mortality in the Munich garrisons during the ten years, 1872-1881.

The great decrease in typhoid fever in Munich since the 18th decade must be attributed chiefly to the removal of these causes, which for so long had been producing extraordinary dampness and pollution of the soil immediately around and beneath the dwellings of the whole city.

From the time that the cesspits were made water-tight, (from 1868), the gradual reduction of active pollution must have been enormous, whilst the natural agencies of the soil, aided by the system of sewerage which has been extended throughout all parts of the city, must have gradually diminished the accumulated stock of dampness and organic saturation.

Finally, the sudden abolition of the 800 slaughter-houses in the city in 1878 removed the chief remaining active agent of soil pollution.

The conclusion that the prevalence and reduction of the typhoid fever in Munich have been independent of the drinking water rests then upon the following evidence:—

(1). PETTENKOFER's own observations made in 1854 and afterwards.

He also observed that those who made use of the PETTENKOFER waterworks water (introduced in 1865 and followed by a great epidemic) suffered just as much from the epidemic as those who continued to drink the old water supplies.

(2). The conclusion drawn by WAGNER and AUBREY from a large series of analyses, that the sub-soil water was more polluted when it was high than when it was low, i.e. that during the periods of typhoid fever epidemics the drinking water was purer than when the typhoid incidence was small.

(3). Dr. POAR's observations on the Munich garrisons, which show that the garrisons which were supplied with exceptionally pure water during the ten years 1872-1881 suffered far more severely than those whose water supply was obviously highly polluted.

(4). Finally there is the great fact that the people of Munich were drinking the sub-soil water, and that only until 1865—three years after the epidemic waves had ceased—when the highland water-supply was introduced. This supply has slowly and gradually been distributed to the whole city. In 1864 PETTENKOFER investigated the typhoid fever mortality in 671 houses containing 33,535 people who were still supplied by the old Munich waterworks. The waterworks had not altered

their supply, and the epidemic waves were still at an exceptionally high level. These facts clearly show that the epidemic waves were not due to the sub-soil water supply. Recently PETTENKOFER and AUBREY investigated the incidence of typhoid fever in certain districts during the years 1886-1891 with the aid of the late Dr. PETTENKOFER's data. They estimated 685 houses in which there were 20,100 cases and found that 67 per cent. of the houses with 70% of the typhoid fever patients had been served exclusively with the highland water-supply.

Dr. CHILDS draws the following conclusions:—
Taking all the above facts into consideration, it must be admitted that the evidence is very strongly in favor of the conclusion that whilst the great decrease of typhoid in Munich has been due in a general way to improved sanitary conditions, and possibly in some measure to decreased pollution of the water, (1) the drinking-water has not played an important part in preventing and reducing the typhoid fever epidemics in Munich; (2) the great prevalence of typhoid fever in Munich was due to the great pollution of the soil (including specific pollution), modified by certain unknown conditions in the soil which are correlated with the movements of the sub-soil water; and (3) the gradual reduction of the typhoid fever was due to the gradual purification of the soil;—and the abrupt termination of the epidemics to the sudden removal of all the slaughter-houses.

The *Lancet*, commenting upon this paper, the value and importance of which it fully recognizes, remarks:—

"The charts of incidence of enteric fever in Munich shewed a striking association between fall of ground-water and increase of enteric fever. In this country it appears that the same relationship holds good, for 1868, 1874-75, and 1893 were exceptionally dry years and were also years of epidemic enteric fever."

"It may be that after neglecting the considerations urged many years ago by PETTENKOFER we shall by this indirect and somewhat circuitous path arrive at a partial agreement with his theory, premising that the great epidemics of enteric fever in a community are nearly always water-borne, while the sporadic cases are due to soil-pollution, and this soil-pollution is most active and operative when the ground-water is exceptionally low and the soil-temperature and humidity are most favorable to the multiplication of the Eberth bacillus."

"If we accept this view, which best reconciles the crepant considerations, there will be no difficulty in recognizing the fact that in order to annihilate enteric fever the soil conditions of each community must be so improved as to starve the Eberth bacillus out of existence. Water is after all but a vehicle of the disease which is generated in the soil."

All this only goes to emphasize the importance of the remarks we have been making on the subject of sub-soil purification in this country, on the probability of the pollution being largely responsible for disease, and on the blindness of the Bombay Corporation in allowing the sub-soil of their city to remain in its present state.

We do not think that anyone who has taken the trouble to read carefully our remarks on "The increased mortality from fever in Madras Town," in our issues of 1st February and 15th February last, can help being struck by the very remarkable parallel that exists between the history of these "fevers" in Madras and the case of Munich as stated by Dr. CHILDS. Such places present the phenomena of a high fever rate in close connection with a low sub-soil water and a highly polluted soil, and we have expressed at some length our reasons for believing that the Sanitary Commissioners in India are in error in ascribing these "fevers" to malaria.

COMMENTS AND NEWS.

THE LATE DR. JUGGO BUNDEY BOSE, M.D.

We quote from Dr. MOHENDRA LAL SENGUPTA, who writes as follows in his excellent paper, the *Calcutta Journal of Medicine*:—"It is with deep regret that we have to announce the death of Dr. JUGGO BUNDEY BOSE, on the night of Monday, the 31st instant. He was born in April 1851. He was educated in the Dacca College, where he first came in contact with the late Babu PROBYNATH CHOPRA SURSADHICARY, whose training did not fail to leave its mark upon the stripling. JUGGO BUNDEY won his junior scholarship in 1869, and retained it next year, having been promoted to what was then called the fourth college class (corresponding to the first year's college class of the present time).

He joined the Medical College of Calcutta in June 1851, and had his scholarship transferred there. He also obtained a scholarship of Rs. 8 a month from the Medical College. At the end of the first year he won the Goodere medal for dissection in Anatomy, and next year he was appointed a prosector to the Professor of Anatomy, Dr. ALLAN WEBB. At the close of the session, he obtained a gold medal in Anatomy and certificates of honor in Physiology and Botany, and his answers in Descriptive Anatomy were printed in the Education Report. At the end of the third year he obtained gold medals in Chemistry and Materia Medica, and certificates of honor in Botany, Anatomy and Physiology. His answers in Materia Medica were also printed in the Education Report. In 1864, he passed what was then called the Junior Diploma Examination, and headed the list of the successful candidates. In the fourth year, he obtained the gold medal in Medicine and clinical prize, the first prize in Midwifery and the Goodere scholarship. At the termination of the fifth session he passed the Senior Diploma Examination with great credit and stood on the top of the list.

"After his graduation, he was sent to Akyab to take charge of the Seamen's Hospital there. Here he distinguished himself as a successful practitioner. As a reward for his services he was appointed second Demonstrator of Anatomy under Dr. H. WALKER in the Calcutta Medical College, and many a student of the College, among whom we are proud to reckon ourselves, still bears testimony to the great success with which he taught dissection. After holding this appointment for about seven years, he became a lecturer to the vernacular classes attached to the College, where he taught Anatomy for six years, and afterwards Materia Medica for twelve years. In 1863, he passed with success the M. D. degree examination of the Calcutta University. We (the editor of this Journal) had the honor of being associated with him in passing this examination. In 1874, the vernacular classes were converted into an independent medical institution under the name of the Campbell Medical School with a Superintendent of its own. He continued to deliver here lectures on Materia Medica, and became also second physician to the hospital attached to the school. He discharged the duties of these dual appointments till 1888, when an attack of paralysis, which had seized him two years previously, forced him to retire from Government service. He was one of the foundation members of the late Bengal Branch of the British Medical Association, at whose meetings he read several interesting papers.

"After his retirement from Government service, he devoted his labors to the establishment of a private medical institution. The Calcutta Medical School has thus sprung into existence. For three years he was its President, and honorary lecturer in Medicine. To promote the study of practical

Anatomy, he induced Government, through the Director of Public Instruction, to allow added lectures to be given at this institution for purposes of dissection. It was largely through his exertions also that an out-door Dispensary was established in connection with the school.

"In 1879 he was appointed a Fellow of the Calcutta University, and for several years Examiner of its candidates for medical degrees. He was a member of the Calcutta Medical Society, a Vice-President of the Indian Medical Congress of 1894, and President of the Medical Association of India established in February of that year. The College of Surgeons and Physicians of Bengal has been established chiefly through his exertions. His love and respect for his parents were exemplary. He enjoyed a large and lucrative practice. He was very jealous of the legitimate dues of the profession, and he was very strict in the exaction of his fees. He was very economical in his expenditure. He had thus amassed an amount of wealth which was considerable for an Indian medical practitioner, not a small portion of which he devoted to unostentatious charitable purposes. He founded a charitable dispensary in the place of his birth, and many of his relatives and acquaintances have derived benefits at his hand.

THE BOMBAY PLAGUE COMMITTEE AND PREVENTIVE INOCULATION

THE Bombay Plague Committee still maintains its attitude of reserve, not to say, of obstruction to M. HAPKIN's preventive inoculation against plague, this attitude is all the more surprising and incomprehensible in face of the daily accumulation of evidence in favor of M. HAPKIN's method, nor are we aware that the Committee has done anything, or given any reason to justify the course it has adopted.

One of the most noticeable features about present-day medicine is the important position assigned to serum methods, and no opportunity should be lost of investigating and testing some of the difficult problems of serum prophylaxis, serum diagnosis and serum therapeutics.

The labors of many distinguished scientists, in all parts of the world, are now concentrated in this direction, so that no question of quackery arises. Such methods have the sanction of the highest authorities.

We do not think it will redound to the credit of the Plague Committee that it has placed itself in opposition to this movement, and that it is willing to let slip so favorable an opportunity of elucidating one of the problems of the day.

In the meantime inoculations are proceeding apace under the aegis of the Bombay Corporation, and M. HAPKIN is likely to obtain all the information and data that he requires, and it is remarkable that his method has so grown in popular favor that natives of all classes are eagerly availing themselves of it.

In our issue of 16th December 1897, we gave a full account of M. HAPKIN's inoculations in the Demase epidemic, and drew a very favorable conclusion from the results, which has since been amply justified.

Recent statistics have shown even more favorable results, as for instance the following from the *Times of India* which "deals with experiments which have been carried out on a large scale in the Khoja community by Dr. HAPKIN at Poona and Bombay. AGA KEAN was at Poona in the height of the epidemic in March 1897, having with him some six hundred followers. Of these four hundred and fifty were inoculated. Of the remaining one hundred and fifty who were not inoculated, 43 were attacked with plague. All except one died. Among the 150 inoculated there was not a single case. Concerning inoculations in the Khoja community as a whole, it should first be stated that every pro-

...has taken to ensure that the experiment on the station side shall be carried out with accuracy. The station officer has been taken of the community, every inoculation is recorded, and the history of each case can be closely followed. The facts then stand thus—The total number of Khojas in Bombay is little over 8,700. From the 27th of December to the 16th of February, 4,020 of them were inoculated, and when to these are added Khojas who were inoculated previous to the first-named date, the total is brought up to a little over 5,300, or a few hundreds in excess of half the community. The mortality statistics now available, however, relate to the period named, that is to say, from the 27th of December to the 16th of February, and in that period 87 deaths occurred in the Khoja community, of which 47 were acknowledged to have been from plague, 45 of these were among the inoculated, now a little less than half the community. Two deaths from plague were registered in the inoculated group, and the history of these two cases is as follows. One was a child six years old who had been inoculated eight and a half months before with only half a proper dose of serum, the other was that of a man inoculated two days after he began to feel unwell, and who died within seven days. The facts may well be left to speak for themselves.

THE DEPUTATION TO THE SECRETARY OF STATE FOR WAR RE THE A. M. S.

We quote from the *British Medical Journal*—"A deputation from the British Medical Association comprising representatives from most of the chief centres of medical education in the United Kingdom waited on Lord LANSDOWNE, the Secretary of State for War, at Lansdowne House, on 20th January. The deputation was introduced by Dr. FARQUHARSON, M.P. Sir THOMAS GRAINGER STEWART, Sir JAMES MOUTAT, K.C.B., V.O., Dr. SAUNDY, Mr. MACNAMARA, Professor O. B. BALL, and Sir WILLIAM THOMSON stated the views of the deputation.

Lord LANSDOWNE in reply, assured the deputation that he was entirely with them in regarding with very serious concern the present condition of the Army Medical Staff. The fact that comparatively little competition existed for vacancies, and that, as stated by the President-Elect and the President of Council, only inferior men presented themselves, certainly pointed to a very grave condition of things and the subject was having the most serious consideration given to it. In proof of this, His Lordship enumerated several matters which had come before him during his present term of office—the position of medical officers on court-martial, medical messing, grant of leave for study, pay of the junior medical officers in India, length of the Indian tour, etc.—all of which had been dealt with, he thought, to the satisfaction of the profession. With regard to the question of the formation of a medical corps and the question of rank, His Lordship said he saw no objection to the formation of a medical corps, but it was intimately connected with the second question, which presented very serious difficulties. He regarded some of the present medical titles as cumbersome and thought it ought not to be beyond the power of the authorities to discover more suitable designations. The matter was one which had been lately examined with great care, and he hoped shortly to be able to announce the decision of the War Office. In conclusion, His Lordship asked whether if the questions of corps and rank were disposed of satisfactorily, the War Office might rely upon receiving from the profession assistance in obtaining the best class of candidates in adequate numbers.

Dr. FARQUHARSON, in thanking His Lordship for his kind

ness and courtesy, in answering the deputation, said that if the constitution of the medical corps and rank titles were made, it would result, in his opinion, in the Medical Department being placed in a most satisfactory position both as regards the number of young medical men entering the service and the qualification of those entering.

THE RONTGEN RAYS ON THE WAR FRONTIER.

A CORRESPONDENT of the *Englishman* writes as follows to that paper:—

"One of the most important features of the campaign has been passed over almost without notice, and that is the Rontgen Rays apparatus which Surgeon-Major BENVOR brought up. Surgeon-Major BENVOR bought the apparatus at his own expense, being on leave at the time, and the help which this new development in surgery has been, is immense. It would be impossible to detail the many experiments made, but this one is sufficiently marked to show of what use the invention is. A native officer of the 36th Sikhs was shot in the thigh on the return from the Dard reconnaissance, and although the wound was probed carefully, no evidence of the bullet could be found. Yet there being no second puncture of the skin, it was evidently still in the leg. The limb swelled terribly, and the wounded man suffered great agony, and it looked as if there would be no other course but that the man should lose his limb. The rays were applied and a mass was found quite in an unexpected place. The surgeons cut down to it and found the bullet, a slug—absolutely enveloped in the wool of a piece of the man's *poshtoon* which it had taken in with it. So enveloped was the lead that it had appeared a soft mass when touched with the probe. As soon as it was removed a thorough drainage for the wound was arrived at, and the pain and swelling at once subsided and the limb was saved. This is only one case out of many, but it is also important as it shows how dangerous a suiting the skin *poshtoon* is. A bullet striking a man thus clothed is certain to take much of the hair of the skin in with it, and the inflammation started by this extraneous matter must aggravate the case. Just one more case in which Surgeon-Major BENVOR's apparatus played an important part, before leaving the subject. A man in the Borderers, I think, was hit in the foot, the bullet breaking up the instep bone and passing out through the sole of the foot. The wound healed in every way satisfactorily, but the man found that he could not put his foot to the ground, and the cause of this pain absolutely baffled the doctors who examined the case. The rays were brought into play, and it was found that a piece of lead had forced its way right into his heel and was resting under the bone. This was but a splinter, and had evidently chipped off the bullet as it struck against the bone. An incision was made, the piece of lead found and extracted, and the patient at once recovered the use of his foot. But for the X-rays disclosing this the cause of the irritation would never have been discovered. Surgeon-Major BENVOR certainly deserves a recognition of his services as there are countless cases which his presence has aided to a cure, and in several cases he has saved wounded men from the loss of their limbs.

TESTIMONY IN FAVOR OF THE VALUE OF ANGLO INDIAN WORK IN INDIA.

TRUE to his genuine good nature, Surgeon-Colonel KENNETH MACLEOD, M.D., F.R.C.S., LL.D., I.M.S., Professor of Military Surgery at Netley, writes to his old journal, the *Indian Medical Gazette* of 1st March, as follows:—"I was much interested lately in reading a report of a meeting which was held in Calcutta not long ago in support of the interests of the Anglo-Indian community. The awakening which has lately taken place in this important section of the population of

Mr. L. J. Burpee is a trusting and generous man, and more than enough credit is my share of the credit due to him for the assistance he has rendered me, and for the excellent work he has done in many capacities in public and private life, and contributed very substantially to the stability and efficiency of British rule in the East. In doing so, particularly, they have done exceptionally well, and I could with pleasure the commendation of Henry's great intellect and kindly willing disposition which it was my duty to assist in training and guiding in the Colonial Medical College. The aspiration for higher position and better education which has been manifested by robust proceedings is entitled to every encouragement and aid, and the formation of an Association in England to represent a class and advocate its claims and hopes are a sound step, and likely to be successful.

"I have no doubt that in the competition which the Anglo-Indian must undergo in the future as in the past with foreign and indigenous races, he will, more than maintain the character for patient industry, 'unweariedness and practical efficiency which he has already acquired."

AN IMPORTANT NOTION AS TO THE EMPLOYMENT
OF UNQUALIFIED PERSONS AS ASSISTANTS
OR OTHERWISE.

The following notice is directed to be issued by Resolution adopted by the General Medical Council on 24th November 1907:—"Whereas it has from time to time been made to appear to the General Medical Council, that some registered medical practitioners have been in the habit of employing as Assistants in connection with their professional practice, persons who are not duly qualified or registered under the Medical Acts, and have knowingly allowed such unqualified persons to attend or treat patients in respect of matters requiring professional discretion or skill; and whereas in the opinion of the Council such a substitution of the services of an unqualified person for those of a registered medical practitioner is in its nature fraudulent and dangerous to the public health: The Council hereby gives notice that any registered medical practitioner, who is proved to have so employed an unqualified assistant, is liable to be judged as guilty of 'infamous conduct in a professional respect,' and to have his name erased from the Medical Register under the 29th Section of the Medical Act 1886.

"Further, in regard to the practice commonly known as 'covering,' the Council gives notice that any registered medical practitioner, who by his presence, countenance, advice, assistance or co-operation, knowingly enables an unqualified or unregistered person (whether described as an assistant or otherwise) to attend or treat any patient, to procure or issue any medical certificate or certificate of death, or otherwise to engage in medical practice as if the said person were duly qualified and registered, is liable to be judged as guilty of 'infamous conduct in a professional respect,' and to have his name erased from the *Medical Register*, under the said enactment.

"But the foregoing notions do not apply so as to restrict the proper training and instruction of *bona fide* medical students as pupils, or the legitimate employment of dressers, midwives, diaponeers, and surgery attendants, under the immediate personal supervision of registered medical practitioners."

**HEROIC CONDUCT OF ENGLISH PLAGUE NURSES
AT THE MODYKHANA FIRE IN BOMBAY.**

Few acts of greater heroism have been recorded in recent years than the saving of their helpless plague-stricken patients from being burned to death, by the brave English nurses in Bombay.

James Earl Ray, alias "Son of a Gun", was born in Jackson, Mississippi, on May 19, 1928. He was a member of the Black Panther Party and was involved in the assassination of Dr. Martin Luther King Jr. on April 4, 1968. He was convicted of the murder and sentenced to 99 years in prison. He was released on parole in 1990 and died of cancer on April 23, 1998.

[illegible]

Their noble example was followed by the ward boys and police officers who were present and rendered the most important assistance.

While the work of rescue was going on, the boat containing all their own property, wearing apparel and valuables was totally destroyed, so that most of them lost everything except what they were actually wearing at the time.

This adds another to the many examples of heroic acts and unselfish devotion to duty, of which the medical profession is so justly proud.

The names of these ladies are Mrs. CAMPBELL, Miss C. BROWN, Miss BUCKLEY, Miss CAMPBELL, Miss FAY, Miss SNOWDON, Miss WINSOMBE and Miss WOOD.

**MEETING OF THE STRAITS SETTLEMENTS BRANCH
OF THE INDIAN MEDICAL ASSOCIATION.**

A MEETING of the Straits Settlements Branch of the Indian Medical Association was held at 8-30 P.M. of the 15th February 1938.

The members present were:—Messrs. A. B. LEICESTER, W. R. ANGUS, R. J. GIBBS and A. HALE.

Mr. AEMIA wrote regretting his inability to attend through indisposition. Mr. J. A. BEARDON attended as a visitor.

The circular calling the meeting was read and the minutes of the previous meeting confirmed.

Mr. CAMMERMEYER's query as to whether it was necessary for him as a member of Committee for Peking to forward correspondence and minutes of the meetings of the Peking members for publication in the *Indian Medical Record* to the local Secretary first, was put to the members who decided that it should be so done.

Papers on Puerisry, Post-partum Hemorrhage and Fractures of the upper extremity were set by Messrs. LEIGHTON, AUGUS and HALE respectively and were gone into by the members present.

On Mr. HALL's suggestion, the following subjects were selected for discussion at the next meeting.

Medicine.—Eruptive Fevers, (a) Variola, (b) Varicella, (c) Measles, (d) Scarlatina, (e) Enteric Fever.

Surgery.—Dislocations of the upper extremity, e.g., shoulder and wrist.

Midwifery.—Pregnancy and the diseases of pregnancy.

The Honorary Secretary was directed to write for a copy of the Indian Medical Directory.

H. J. GIBBS, Honorary Secretary.

THE TEACHING OF SURGERY AT THE CALCUTTA
MEDICAL COLLEGE.

THAT surgery is well taught at the Calcutta Medical College, goes without saying, as with two such strong representatives of the art, as Surgeon Colonel J. GRIFFIN, M.D., F.R.C.S., and Surgeon Lieutenant Colonel E. HARRINGTON CHARLES, M.D., F.R.C.S., the good old school is bound to do well served. During Dr. CHARLES' absence an agent was deputed to visit the Surgeon Lieutenant Colonel J. LAWRIE, M.D., F.R.C.S.,

new opportunity happens that Dr. O'BRIEN is desirous of going away to Europe to leave and there arises a serious difficulty in filling his place as Professor of Surgery to the College, and First Surgeon to the Medical College Hospital. So difficult is the situation that it is feared a "job" will be committed and a bad surgeon put in to do good surgery. Of course this is bad management, and as both the public and the students are certain to suffer by such an arrangement, we enter a respectful but earnest protest against an incompetent man being foisted on to the College staff. If the Government is in straits about finding a good man, it might very advantageously look about among the independent English Surgeons of Calcutta, and find a man eminently fitted to fill the Second Surgeoncy of the Hospital and the Professorship of Clinical Surgery, while Professor CHARLES (or temporarily Professor LANGE) might fill the first Surgeoncy and Professorship of Surgery during Dr. O'Brien's absence. We refer to Dr. ARNOLD CADDY, F.R.C.S. Eng. who might with immense profit to the College and Hospital be appointed to fill the approaching vacancy.

BOGUS AMERICAN DOCTORS.

THE *Medical Times and Hospital Gazette* says—"Among the army of unqualified practitioners now operating in the metropolis of the British Empire, the most audacious as well as the most successful financially, are the Yankee quacks. They fill the columns of our newspapers with the most wonderful stories of their cures of the blind, deaf and halt, and they attract thousands of dupes, who pay these pretenders large sums of money for their services, far beyond what they would think of paying hospital specialists for similar services. It is curious that these men never get into trouble for malpractice, notwithstanding that they often perform risky operative methods of treatment, especially as they are unqualified and untrained when they arrive in England we have learnt recently that these men, on arriving, lose no time in visiting the wards of our special hospitals, and attending the clinics of the leading physicians and surgeons. The presentation of a neatly-printed card, describing the owner as Philadelphus Chicago, M.D., U.S.A., ensures the free run of the hospital wards and out-patient departments week after week, until they have picked up all that can be taught. Sometimes they attend post-graduate courses in special subjects, and in this way, although the most arrant knaves, acquire a certain amount of skill, which enables them to carry on their quackery with the minimum of risk. Unless properly introduced, hospital tramps hailing from the United States, and calling themselves M.D.'s, should be rigidly excluded from seeing hospital practice except as patients."

FLIES AS CARRIERS OF INFECTION.

In a recent number of the *British Medical Journal*, Surgeon-Major J. BATTERSBY, M.B., D.P.H., A.M.S., writes as follows—"The recent discussion at the Royal Medical and Chirurgical Society on the prevention of enteric fever has re-called a letter of mine which you did me the honor of publishing in your valuable journal, dated 10th August 1895. In that article, in addition to the waterborne theory, I drew particular attention to the part taken by the common house fly as a possible carrier and disseminator of the disease. Any person who has visited Egypt or the plains of India during the earlier months of the hot weather can, I think, bear corroborative testimony as to the clouds of flies everywhere met with. Observation soon teaches us as to their disgusting habits and modes of feeding, utter disregard being shown as to whether they swarm in unenviable competition on the stools passed by enteric, choleraic, or dysenteric patients, etc., or choose the articles of food and drink of which we may be

the unhappy partners. In their rapid movements from one sort of filth or food to another, have we not got strong presumptive, if not demonstrative, evidence as to a possible manner in which the morbid material may be conveyed to the alimentary canal? Those of us who have witnessed the marvellous way in which the comma bacilli of cholera can multiply on agar jelly within twelve hours from the minutest inoculation, do not wonder why other bacilli (enteric for instance) cannot act a similar part when carried and deposited by flies, either by their limbs or dejecta, on suitable pabula. The bacillus typhosus has been demonstrated in the dejecta of flies previously fed on enteric matter."

ENTERIC FEVER IN INDIA.

SAYS the *British Medical Journal*.—"In consequence of the heavy mortality from enteric fever among British soldiers in India, the Government of India has under consideration a proposal to apply to the Home Government for a loan of the services of Dr. A. E. WRIGHT, Professor of Pathology at Netley, for a period of four months; possibly with a view to vaccination against typhoid, which we noted on November 6th. We understand that no definite arrangements upon this matter have yet been made.

Respecting the mortality from enteric in India, we may give the following numbers in the years 1891 to 1895 inclusive—

Year.	Admissions.	Deaths.
1891	1,348	880
1892	1,506	874
1893	1,402	870
1894	1,484	408
1895	1,544	888

Total in five years, deaths 1,915, equal to approximately nearly two battalions at full strength. The inefficiency and in-fallibility are not here considered.

In consequence of the large number of deaths from enteric at Agra, a special committee, composed of the military municipal, and cantonment authorities, will shortly be assembled to inquire into the cause of the outbreak. The establishment of a Government dairy for the supply of milk to the troops and hospitals is under consideration."

THE LEGAL POSITION OF QUALIFIED MEDICAL MEN.

SAYS the *Lancet*.—"The privileges conferred by law upon duly qualified—that is registered—practitioners, are as follows:

1. They can sue for their fees.
2. They can sign valid certificates.
3. They are exempt from serving as jurors, and also from the militia ballot.

4. They are entitled to practice medicine, surgery, and midwifery in the United Kingdom and the British possessions.

A privilege conferred by Acts of Parliament becomes a legal right capable of enforcement by law, and it follows that all persons other than those duly registered cannot legally, in addition to other disqualifications, practice medicine, surgery, or midwifery in the United Kingdom or the British possessions.

It may be asked, what penalty is incurred by those who do so practise without being registered? To this the only answer can be that by so practising they usurp the legal rights of the duly qualified, and that by doing this they imply to a credulous public that they are registered, and that Section XL of the Medical Act, 1858, could be put in force against them. If magistrates and judges in dealing with these cases could be brought to understand that registration is the only portal for legal practice of medicine, no difficulty would ensue in dealing with unqualified practice. In cases about to come before the courts, these points will be driven home, and, it is trusted with success.

SANITARY WORKS ADMINISTRATION IN PUNJAB.
 Sanitary Engineering calls attention to the fact that the administration of sanitary works in this country has much to be desired.

On the authority of Mr. FORTMESS, Sanitary Engineer to the Government of Bombay, the North-West Provinces deserve commendation in this respect. Here an official specially selected on account of his Sanitary Engineering knowledge, was appointed for supervision of such works in 1887, synchronously, the Water-Works Act of 1881 was passed.

With power and funds thus possessed, aided by grants from the Local Government, efficient works were rapidly constructed, large firms of contractors being employed under supervision. Unfavorably contrasted with this is the system adopted in the Punjab. Here the projects are apparently both drawn up and executed by the P. W. D. Officers, who have not been specially selected for the duty and, consequently, have not made the study of water and drainage schemes their special study. As a consequence, works during construction have been altered and re-altered; in one case at least a disastrous failure occurred. The only other system which has proved as unsuccessful is that which was passed in Madras till about a year ago. At present the Madras Sanitary Engineer draws up schemes which are handed to the local officers of the P. W. D. to accomplish. This practically leads to the same result as the system in force in the Punjab.

LUSTIG'S PLAGUE VACCINE.

SAYS the *British Medical Journal*:—"It is announced that Professor A. LUSTIG, Director of the Institute of Experimental Pathology in the University of Florence, has responded to a request from Bombay to forward a quantity of his plague vaccine by promising to send his assistant with an ample supply. The vaccine serum was tested last year in Bombay and Poona on patients with an encouraging result. When the injections were made at an early stage a beneficial effect was noticed in six hours; the high fever and delirium ceased and general improvement ensued, the glands ceased to be painful after two or three injections, and convalescence was less prolonged than in cases which recovered without this treatment. Of thirty cases of the disease subjected to this serum treatment, only four died. In healthy persons the serum does not produce any disturbance, but there is reason to believe that it has the effect of protecting against plague infection. This, however, is a point upon which further evidence is required, as Professor LUSTIG when in Bombay, found it impossible to overcome the objections of the natives to submitting to the necessary injections. It will be remembered that his method of vaccinating animals against the plague bacillus was described by Professor LUSTIG and Dr. GALWORTHY in our columns last April."

PLUMBERS AND PUBLIC HEALTH.

THE answer that is usually given to anyone who is bold enough to criticize the elaborate system of sewers which modern sanitation imposes on the tax-payer, is that it is wrong to blame the system for faults in construction or workmanship.

As an academic display the reply might pass muster, but practically it is no answer at all, for all past and present experience has shown us that a perfectly constructed system of sewers is an impossibility, and that in spite of the countless patents and improvements every such system possesses many elements of danger.

Now that these things have been made fairly clear, people are beginning to set to work at the right end, and the land

owners among our nation are beginning to take notice of the fact that the position of the sewerage system in England is such that we may have to give both the position and the system a new lease of life for the sake of the Public Health.

If there is such a thing as a "plague" in the air, we can certainly hope to keep it out of our doors by it.

NEMATODE WORMS IN THE BLOOD. NEW SPECIES FOUND IN AFRICA.

DR. PATRICK MANSON, in a paper read at the meeting of the British Medical Association in November and published in the *British Medical Journal*, 26th September last, calls attention to the presence of several species of nematode worms in the blood.

"It is probable," he says, "that we know of at least six nematode worms, or embryo nematode worms inhabiting the blood of man, namely, *filaria nocturna* (filaria *Hamorrelli*—mature form), *filaria diurna*, *filaria perstans*, *filaria Demarquay*, *filaria Megalhaesi*, and a new *filaria* of Demarquay which provisionally he has named *filaria Ozzardi*.

It is a curious thing, he remarks, that amongst the Guiana Indians *filaria nocturna* appears unknown, which fact is doubtless correlated to the fact of the absence of Elephantiasis Arabum amongst them.

Dr. OZZARD mentioned that when travelling amongst the Indians, a woman was brought to him for treatment, who was always asleep. Dr. MANSON has suggested that the sleeping sickness of West Africa is in some way bound up with *filaria perstans*.

AGRA MEDICAL MISSIONARY TRAINING INSTITUTE.

WE gladly give prominence to the following advertisement:—"The Agra Medical Missionary Training Institute has for its object the imparting to Native Christian youths a systematic knowledge of Divine truth, to prepare them for the work of medical missionaries healing the sick and preaching the Gospel.

The students live in the Institution and receive their professional education and diploma at the Agra Government Medical College.

The medical curriculum extends over a period of four years.

The classes commence on the 1st of July.

Intending students should however be present not later than the 26th June.

Liberal scholarships are provided for deserving students. It is also proposed to open a class for the training of compounders.

Prospectuses to be obtained on application from Rev. Dr. VALENTINE, F.R.C.S. Edin., Principal, 24, Drummond Road, Agra.

INOCULATION AGAINST PLAGUE.

HER Majesty's Justices of the Peace for the Town and Island of Bombay, held a meeting on Wednesday, 2nd March, in the Durbar Room of the Town Hall at which the following resolutions were unanimously passed.

First Resolution.—"That the members of this meeting being of opinion that more effective steps should be taken to induce the inhabitants of Bombay more generally to avail themselves of the opportunities offered them of being inoculated against plague, undertake individually to use their personal influence in persuading the inhabitants of Bombay to get themselves inoculated."

[illegible]

PLACED IN CUSTODY

There was a decrease of deaths from plague for the week ending 18th February and 1,375, for the week ending 22nd February 1,382, and for the week ending 28th March 1,388 an increase of 134 over the week before.

It is ascertained that the present epidemic has reached its height and is now on the decline. It is however as yet too early to express a positive opinion.

It is observed that the disease is not spreading so rapidly, and that there are still seven districts that have not been attacked with any degree of severity.

It is interesting to note that the intensity and distribution of the plague is not the same as it was in the first epidemic, the districts over which it has passed suffering proportionately.

tely either less or more. It has, moreover, spread in the same direction from south to north and from east to west.

THE STORY OF A BARBER SURGEON.

We quote from the *Lancet*:—"An inhabitant of a little village near Mainz fell down and seriously injured his arm which became swollen and very painful. The village barber surgeon was appealed to and ordered applications of Goulard water—in German, *Bleiwasser*. The patient's wife, however, being very anxious, on arriving at the village shop made a mistake and asked for *Wasserbl-i*, or blacklead. On arriving at home she mixed this with water and rubbed it well over the injured arm, finally polishing the limb with flannel. This treatment had an excellent effect, the pain disappeared and the swelling went down. Next morning the barber called to see how the patient was getting on and was met by the delighted wife who congratulated him on the efficacy of his treatment. Upon seeing the arm, however, which of course was quite black, he was horrified. "What," he said, "so pain, of course he doesn't feel any pain, the arm is quite dead, gangrene has set in, and if the arm is not taken off at once he will die." A surgeon was duly sent for who, of course, discovered the real state of the case. What happened to the barber is unfortunately not stated, but we fear that most unqualified practitioners do not see such favorable results from their prescriptions as did their German brother."

FEMALE ABORTIONISTS.

The *Medical Times and Hospital Gazette* says:—"For the purposes of abortion, the modern trained midwife is invaluable. She can bring on abortion. She has learnt the art. Poor Mrs. GAMR was a failure at the business. She seldom succeeded in doing more than making the patient ill, though seldom dangerously so. Here is the *modus operandi* in such cases. The patient confides in the chemist, takes his medicine for a time, and finally is recommended to the

[illegible]

**SPECIAL OFFICERS SANCTIONED FOR THE
SANITATION OF CANTONMENTS**

With a view to improving the military administration of the Government of India, has sanctioned the appointment of an experiment of three specially qualified military officers, who will be appointed to the stations of Lucknow, Kanabedi and Umballa, and whose sole duty it will be to investigate the causes of disease and give practical advice in sanitary matters. These appointments will take effect from 1st April next, and will be for three years in the first instance. One of them will be held in abeyance, however, during the employment of Surgeon-Major DAVIES on special bacteriological investigations. The pay will be that of a Civil Surgeon in charge of a second-class station, viz an allowance of Rs. 100, rising by annual increments to Rs. 300, and a deputation allowance of Rs. 8 daily when absent from the head-quarters station.

A LADY DOCTOR'S WORK PUBLICLY AC-
KNOWLEDGED.

A POONA correspondent writes:—“There was a large gathering of European ladies and gentlemen and native Hospital Assistants and others in the centre of the General Plague Hospital at the Sunnam to bid adieu to Dr. (Miss) Marion Hunter, who is returning to England from her duty in the Plague Hospital. General Durnan said they were all very pleased to attend and do honour to Dr. Hunter, a lady who had left her associations and her comfortable home in England to come out and work in this country among them. She had labored day and night among the plague-stricken. As a lady doctor, Dr. Hunter had earned the gratitude of the people of Poona, and not only of the patients she had ministered to. The name of Dr. Marion Hunter would not be forgotten in Poona.”

BOMBAY AND THE PLAGUE

The plague continues, writes the *Times of India*, and the general health of Bombay remains almost unchanged. The weather conditions have been variable during the week, hot and cold alternating suddenly, and the thermometer in-doors ranging from a minimum of 68 to a maximum of 84 Fahrenheit, with no appreciable influence on the progress of the plague. But concurrently with the plague, two other epidemics, influenza and relapsing fever, are affecting the public health. No record is kept of the mortality from influenza, but as the mortality recorded from diseases of the respiratory system has risen from a five years' average of 106 to 229 in the present week, some portion of the increase of mortality of 154 may be suspected to be due to plague and a smaller portion to influenza.

FURTHER MEDICAL ASSISTANCE FOR INDIA.

The Secretary of State for India, has selected from the list of volunteers previously received, eight more medical men and two more medical women, who proceeded to India on 28th January, for work in the plague districts. If plague should spread to other parts of India (outside the Bombay Presidency) still further reinforcements will be necessary, and in order to meet such demands, the India Office invites volunteers to send in their names to be put upon the list. The terms of appointment and other information will be sent

to any qualified practitioner who may apply to the Revenue Secretary, India Office, Whitehall. The India Office intend also to send twenty-five more nurses, if the complement can be made up in time.

NEW MEMBERS OF THE INDIAN MEDICAL ASSOCIATION.

THE following have joined the Association since our last publication :—

Taharat Hussain, Khaz Sahib, C.M.S., 16th Regiment B. I. Malakand.

Syed Ahmad Hussain, C.M.S., No. 5, N. Field Hospital, Camp Khar, Malakand.

Teghah Khan, C.M.S., Camp Khar, No. 5 N. Field Hospital, Malakand.

B. K. Gupta, L.M.S. Assistant Surgeon, E. B. S. Railway, Sealdah.

C. Mangaya Nayudu, C.M.S., Medical Officer, Chittoor.

Syed Abdull Khadir, C.M.S., Civil Hospital, Tharrawaddy, Burma.

F. H. Gleeson, Assistant Surgeon, Camp Barkai, (T. E. T.)

Julia Bissell, M.D., American Mission, Ahmednagar.

REMARKS WORTH NOTING.

MR. BAPTIST, a dark gentleman, of Portuguese descent from Bombay, was lately addressing a meeting in York, England. While thus engaged he was interrupted by one of the audience who called him a "black-man." I prefer being that to being a blackguard, was his prompt and immediate retort, and the man who had interrupted him had to look extremely foolish and hold his peace. *As a result* of this, a contemporary tells a story which will repay perusal. A Scotchman once asked a Bengali gentleman what difference there existed between a Baboo and a Baboon. The answer was as prompt as it was effective. "The difference is only of one letter as between a *set* and a *Seet*," and the interrogator had the table turned against him.

RIGOROUS PLAGUE RULES AT BOMBAY.

It is stated that strict rules are to be introduced in order to arrive at the true causes of mortality in Bombay. It is proposed to demand in every case of death from whatever cause a medical certificate giving the true cause of death, failing this all bodies will be examined by the authorities at the place of the disposal and the cause ascertained. This has been heard with considerable apprehension by the Mahomedan community. Their customs do not admit of bodies being touched after death, and consequently the Mahomedans look upon the proposed regulations as a violation of their religious customs.

ROMAN TABLE MANNERS.

DR. T. LAUDER BRUNTON, in his "Lectures on the Action of Medicines," says :—"If any of you have been to Rome you will have seen in the palace of the Cæsars a small room adjoining the banquetting-hall; this is pointed out as being the place in which the Romans used to empty their stomachs when they had eaten so much they could eat no more. Then, having emptied their stomachs, they went back and finished the feast. In these Roman feasts the food was admirable in regard to quality, and was objectionable only in regard to quantity.

MARRIAGE AS A PREVENTIVE OF INSANITY.

MATRIMONY, already noted as a specific for longevity, is now coming into prominence as a preventive of insanity. An American statistician has it that, so far as concerns the United States, six times as many bachelors as benedicts lose their reason. It is absurd to meet this grave physical truth with the flippant remark that those who marry are out of their minds at the time of taking the step. Figures are figures—even to bachelors.

WHERE TO FIND THE PLAGUE BACILLUS.

A MEDICAL friend from Hyderabad writes to me on the 15th March as follows :—"I have found the plague bacillus in the ground of infected houses in the villages of the Nizam's Dominion, so has Dr. BURNARD. The infection is in the floors and not in the walls or roofs of houses, and it can be traced about as certainly and almost as easily, as if visible to the naked eye. It can be destroyed with certainty by fire, probably also by water."

SHORT ITEMS.

In Paris the physicians have sufficient sense of the proper mutual protection which is their right to publish a "black book" containing the names of would-be swindlers, and to refuse attendance upon those who treat medical men disgracefully. Inhumanity cannot be brought forward as an argument in a large city well supplied with public charities, night service, quick ambulance system, and all other means of succour for those too poor or too mean to pay a doctor's fee.

The despatch from General Sir W. S. A. Lockhart, K.C.B., K.C.I.E., Tirah Expeditionary Force, published in the *Gazette of India* of the 6th March, besides making honorable mention of several members of the Army and Indian Medical Services, as well as of the Medical Department, says :—"The officers of the A. M. S. and of the I. M. S. have fully maintained their high reputation by their attention to the sick and wounded, both under fire and in hospital. The hospital arrangements were 'generally excellent.'"

The Royal College of Surgeons of Edinburgh offers for competition among its Fellows and Licentiates the sum of 100 guineas for an original unpublished essay on a subject in any branch of surgery, or in anatomy, physiology, therapeutics, or pathology bearing on surgery. The conditions of the prize will be furnished on application to James Robertson, Solicitor, 48, George Square, Edinburgh, Clerk to the College.

Dr. W. S. Playfair, having reached the age limit, will retire from the duties of the chair of Obstetric Medicine and the Diseases of Women and Children at King's College, London, together with those of the appointment of physician for diseases of women and children and physician accoucheur at King's College Hospital, at the end of the winter session. Dr. Playfair has been connected with King's College and King's College Hospital for the past thirty-five years.

It is announced from Naples that Dr. Alessandro Lustig, Professor of Experimental Pathology, has received from the Bombay Municipal authorities a pressing request to despatch, with all possible speed, a quantity of serum. The Professor has decided not only to comply with this request, but also to send to Bombay his chief assistant, Professor Nakou, whose services will be given gratis.

In a despatch from the late Major-General Yeatman-Biggs, Commanding the Kohat Field Force, that officer highly commends Surgeon-Captain O. B. Frail, I. M. S., and Miss Theresa M'Grath is mentioned as having rendered most valuable assistance to the medical officer. Her conduct is spoken of most enthusiastically by all ranks."

Brigade-Surgeon-Lieutenant-Colonel Sir George King, M.B., LL.D., F.R.S., was entertained to a farewell dinner, given in his honor, by his brother professors of the Calcutta Medical College. The dinner was held at the United Service Club, and Surgeon-Colonel Romford, Principal of the Medical College, presided.

Common Sorethroat.

There is pain, itching, fulness of throat, with continued tendency to cough, coryza, fond breath, coated tongue, quick pulse, sometimes febrile symptoms, pain on swallowing, impaired hearing and articulation, hoarseness, bright red fauces, swollen elongated uvula. By and by the uvula membrane becomes swollen, the tonsils inflamed and large and coated with a grayish white membrane depleted by the discharge from the uvula, and a secretion which issues from the tonsillar follicles is small yellow, or white dots, which do not become confluent (as from diphtheria) on the surface of the uvula or the surface of the tonsils, but are effused on the surface.

Open the door to a new world of possibilities.

J. M. T. FERRY described the operative procedure which he has successfully employed in the case of general suppurative peritonitis, including the following interesting method also. "After a long incision, some double-curved intestine outside the abdominal cavity is brought out, unswelling the patient for the time being, and then thoroughly and systematically wipes out the peritoneum, and with large pig-styunt gauze wrung out of hot salt solution; paying special attention to the pelvic portion. Next, the small intestine is cleaned thoroughly and replaced in the abdomen, and the incision closed save at one point where a gauze drain protrudes. In order that a fair chance of success may be given, the operation should be performed within a few hours of the intestinal perforation which leads to the peritonitis."
Brit. Med. Jour.

Dr. X. DeLoze reducing transients to a minimum, radically cures hydrocic and renders relapse impossible by obliterating the sac in the following way:—

Run a three inch cut along the anterior and most dependant part of the scrotum exposed, and rapidly separate the tunica vaginalis with the finger to a greater part of its extent, next incise the tunica and turning the testes out through the incision cut away one-third of the parietal layer of the tunica vaginalis, after which turn the remaining part inside out and fix it behind the testicle by means of catgut sutures. Replace the testes in the scrotum, interpose an iodoform gauze drain at its lowest part and close the cutaneous wound with silver sutures. The patient remains in bed for 8 days at least. For the first 24 hours there may be a sero-sanguinolent discharge, but the gauze may be removed at end of the second and the scrotal sutures on the eighth day, when the patient may, in the greater number of instances, resume his duties.—*Lyon Medical*.

DR. DUNDAS GRANT summarizes thus the causes and conditions incidental to this annoying symptom: "A useful clinical division is into noises occurring (1) with defective hearing, (2) with abnormal action of hearing, and (3) with normal hearing. If noise be pulsating in character, we can determine if pulsation is produced in middle or internal ear by observing whether it is arrested by pressure on the common carotid or on the vertebral arteries. If pulsating noise be lessened on lying down it is probably anemic; if audible on auscultation, think of intracranial aneurism. If non-pulsating and low-pitched, it suggests venous congestion, especially, if made worse by lying down and relieved by purgation. 'Sea-shell' noise is usually due to contraction of tensor tympani, and occurs in chronic middle-ear catarrh, or may be reflex in character. In obstinate tinnitus with middle-ear disease always try injections of cocaine, through the eustachian catheter, and the daily use of gray powder night and morning. The constant patient is of no use unless there is no middle-ear catarrh. When the bromides fail to relieve try quinine systematically, beginning with a quinine grain three times a day. If quinine does give iron with a minimum of effect."

CHLOROSIS AND CYSTOCELE.

Fetal Inversion of Uterus from Traction on Cord.

CALLED in to see a woman whom it had eighteen months previously delivered with success at a twin labor, KAPANEWSKI found the woman quiescent and lying in a pool of blood with a mass as big as a child's head projecting out of her vulva. It was a total inversion of the uterus caused by a village midwife pulling violently on the cord in trying to extract the placenta, which still adhered partially to the uterus, to which were also attached the fragments of the membranes. The uterus was pressed back into the vagina when it suddenly refused itself without further manipulation; but the patient, who had lost a large quantity of blood, lost consciousness and died in a few hours. The child was still-born, and an autopsy was not practicable.—*Monats. f. Geb. and Gynäk.*

Lithotomy Posture in Parturition.

REFERRING to his own practice of the last eight years, to DRIVER'S observations on 890 lying-in women, to the experiments of WALCHER, KLINER and BERNIER on dead subjects and to the view of the old obstetricians that nature makes the pelvis movable for parturition, Dr. OSCAR SCHMIDT of Moscow claims that by laying the woman on her back with her knees spread wide apart, her toes everted and her thighs flexed on to the pelvis in the lithotomy posture, at the beginning of each pain, parturition is facilitated by the intra-abdominal pressure being increased and enlarging the pelvic outlet through the maximum separation of the pubic bones and the tuberosities of the ischia producing a tendency to lateral expansion of the pelvis, and other pathological conditions that almost without exception minimize the risks of and rarely necessitating forceps delivery. With the cessation of each "pain" the limbs are allowed to resume their natural posture on the bed, so as to not over-fatigue the patient by keeping her in the same strained position for the entire labor period. This is especially true of puerperae in whom there is so often a disproportion between the size of the head and of the vulva, compelling recourse to forceps which, used in the favorite position now in vogue, do great injury to the vagina and perineum, but in the lithotomy posture are harmless.—*Central für Gynäk.*

Tubal Mucosa in Tubal Gestation.

CLARENCE WEBSTER, like FRAENKEL and ABEL, claims to have detected a true decidua in the tube in cases of tubal pregnancy. BLAND SUTTON denies that a tubal decidua exists. WEBSTER insists that FRAENKEL, ABEL, and himself did not endeavour to prove that a decidual formation might develop in the gravid tube, but, on the contrary, discovered decidual tissue in examining tubes purely with the object of defining their histology. FERRY'S theory, on which SUTTON'S views are based, is a mere hypothesis, as there is no reason to believe that he ever examined a section of pregnant tube through the microscope. WEBSTER further maintains that if the placenta be examined in the case of an early pregnancy where escape into the peritoneal cavity has occurred, it presents appearances much the same as those found in the placenta of a miscarriage from uterine pregnancy, the maternal surface being covered with the thin superficial layer of the decidua serotina, irregular in its thickness and distribution. This irregularity is more marked in the case of the tubal than in the uterine placenta, because the development of the placenta in the tube wall is more irregular in the former.—*Brit. Med. Jour.*

Metrorrhagia and Menorrhagia.

It is usual to forbid girls suffering from persistent uterine hemorrhage to marry till the menorrhagic stage passes or less; but Mr. BURNPINE tells us how for six years the whole system of tampons, dilatations, pessaries, tonics and even coagulation of the vagina failed to even diminish a rebellious metrorrhagia in a young girl, who became so weak that she was scarcely able to leave her bed for more than 45 to 100 minutes per day. She accepted an offer of marriage, and during her engagement coagulation was practiced every third day, so as to make a good appearance and set up in the presence of her betrothed who was not taken into the secret. The discharge was quite as free (as before) on her wedding day, but entirely stopping the next morning did not come on for three months. Everyone thought she was pregnant, but on the 92nd day there was a return of the menses with pain and a very profuse flow which ceased spontaneously on the fourth day and gave rise to a no less stubborn amenorrhoea which threatens to remain permanent as it has for two years resisted the entire gamut of emmenagogues, but though her hysterical temperament persists, the woman's general health seems to have improved and she has gained considerably in color, weight and strength.—*Jour. des Sci. Méd. de Lille.*

Is Operative Interference Legitimate in Non-Hæmorrhagic Fibroids after the Menopause?

It is not easy to lay down an emphatic *yes* or *no*, and Dr. G. APOSTOLI of Paris tells how Madame S—, *et. 57*, who ceased to menstruate at 53, never had metrorrhagia or abdominal pains nor bore a child, but was hysterical all her life. Marrying at 38, she 18 months later passed through a typical *grossesse nerveuse* (pseudo-cyesis) and was widowed at 38. From 40 to 45, she suffered much from rheumatism, and at 53, she had severe dyspepsia with loss of appetite and flesh and such an intolerable pain in her head and the whole of her body that prevented her work and forced her to consult a gynecologist, who detected a large uterine fibroid of which she was not aware, as it gave rise to neither bleeding nor local pain. After the removal of this tumour Madame S— improved wonderfully in health and Dr. APOSTOLI, who is inclined (*Treatment*) to attribute the improvement to the shock of the operation determining a healthy reaction in the nervous system of a hysterical constitution and concludes: (1) that except where positive indications such as re-appearance of the hæmorrhage or marked increase in the size of the tumour, women who have uterine fibroids after the menopause and who do not present symptoms directly referable to the presence of the tumour should be subjected to surgical procedures, and (2) such tumour ought not to be regarded as the cause of disturbances of the nervous system unless general and local medical treatment have failed to relieve them. (3) Such cases may be submitted to operation only when such general treatment (coupled with local measures such as douche, massage and electro-therapy) has completely failed to give relief.—*La Presse Médicale.*

Trace of Gartner's Duct in Adult.

BURKHARDT examined a uterus removed for obstinate endometritis. The patient was 41, and had borne three children; the last was 9 years of age. A distinct cystic body was found in the wall of the cervix somewhat anteriorly. It measured 14 mm., or just over half an inch in length and 7 mm. in breadth, and contained an albuminous fluid. It was lined with a perfect layer of cubical epithelium, which had no connection with the histologically different epithelial layer of the cervical mucous membrane. From its position and structure this cystic structure was undoubtedly a relic of Gartner's duct.—*Brit. Med. Jour.*

CATARACT IN THE MADRAS PRESIDENCY OF SOUTHERN INDIA, WITH A STATEMENT OF FIVE HUNDRED CASES.

By ROBERT-MAJOR T. H. POSE, M.D., C.M., F.R.C.S., B.Sc. Edin.

Surgeon Superintendent, Madras Ophthalmic Hospital, Fellow of the Madras University.

CATARACT has been so thoroughly investigated and discussed by ophthalmic surgeons in all parts of the world that little, if anything, new can be laid before the profession ament this interesting lesion. The object of this article is to show the amount of good work done by the Madras Ophthalmic Hospital, which belongs to the State and is maintained at State expense for 80 beds (in 11 wards) for in-patients of both sexes, of all creeds and nationalities, and an out-patient department with an average daily attendance of 120 patients. The professional work is carried on by two qualified Hospital Assistants and an Assistant Surgeon under the orders of a Surgeon of the Indian Medical Service, who is termed the "Superintendent" and has to himself perform all operations, whether major or minor.

From 1,900 to 2,000 operations (of which 70 per cent, at least, are extraction of lens for cataract) are annually performed at this hospital, whose systematic management etc. continue to be conducted even to the smallest details of clinical and other duties, on the lines initiated and kept going for many years by Brigade-Surgeon DRAKE BROOKMAN, F.R.C.S., (retired) who earned a world wide reputation as an ophthalmic Surgeon and brilliant operator, and was the writer's direct predecessor as Superintendent.

Of the 80 beds in hospital the 60 are which allotted to native patients are almost always full, although the cases that are operated on are kept the shortest time compatible with the safety of the eye, to enable attention to be given to the large number constantly seeking admission. Thus while only those cases, where operation is followed by iritis, cyclitis or panophthalmitis, are permitted to remain in hospital for prolonged periods, all those whose lenses have been extracted are discharged on the Wednesday or Thursday following the Saturday they were operated on, and the success of each operation is tested by examining the state of the vision on the evening of the day of discharge from hospital. If there is the slightest doubt as to the satisfactory condition of the eye operated on, the patient is kept under observation by being asked to attend as an out-patient for a few days after discharge from hospital.

The following table, which gives some little idea of the magnitude of work done in this hospital, shows the number of operations performed from 5th November 1892 to 2nd April 1893, i.e., on 21 Saturdays.

In the above classification the term Christians includes Europeans, Eurasians and East Indians, who form a very small percentage of hospital work, and in many respects resemble their brethren and kinsmen of the West as far as surgical operations and the results thereof are concerned, but among the East Indians are a number of persons (native converts perhaps) who have no European trace about them, and these, as a rule, are of feeble constitution in old age, and though they stand the operation well, they do not afford so hopeful a prognosis as the European.

The Hindus are natives of India, and though they profess many castes and creed, may be divided into flesh-eating and non-flesh-eating, in which latter category are the Brahmans or priestly tribe, and who being very particular as to food and cleanly in their habits enjoy better health than most other Hindus; but they are peculiarly subject to (1) diabetes mellitus and (2) granular conjunctivitis, which some surgeons look upon as serious complications in cataract operation. The writer is not prepared to agree with this, as he has never been able to satisfy his mind as to what is really meant by a diabetic cataract, and has frequently successfully extracted lenses from natural cataracts of persons whose urine was heavily charged with sugar. In acute granular conjunctivitis accompanied with photophobia, purulent discharges, blepharospasm or a burning sensation in the mucosa of the palpebral conjunctiva, operation is forbidden, but it can be safely and successfully resorted to in the chronic stage so long as proper antiseptic precautions are taken and there is neither pain nor symptoms present referable to active mischief. The antiseptics should be supplemented by gently brushing the everted lower lid with a solution of nitrate of silver (grs. 3 to grs. 5 to distilled water). The normal eye of the Brahmin is a typically fine organ in which operations, when performed, lend to most satisfactory results.

The largest number of hospital patients are flesh-eating Hindus, such as Moolalars, Naidus, Chetties, Pillais, Sudras, &c who frequently (not always) yield good operative results and are physically stronger than the finely nerved Brahmin, but are not so generally healthy nor is the sclerotic coat so white, and the ocular conjunctiva is often congested and stained brown while the lids are thick and coarse.

The Malayalis or Malabaris are Southern Indians, who may or may not be flesh consumers, and are of inferior physique. With them a cataractous condition of the lens is often associated with atrophy or other functional deterioration of the optic nerve which may itself cause blindness and render it useless to operate for cataract. In rare instances this nerve failure has been improved by hypodermic injections of strychnine solution.

The Mahomedans as members of a warrior class are generally fine specimens of the native and constitutionally strong by virtue of their mixed diet. Their eyeballs resemble those of the Brahmin and react favorably to operations.

The *paras* belonging to the lowest class have no caste principles. They eat everything, are intemperate as a rule, and not very cleanly. They range from the robust hard working cooly (labourer or navvy) to the weakly half starved scavenger, and do not take kindly to

operation, which their diet is usually supplemented by a few ounces of country liquor.

The subjects for operation were of all ages, from years old to 62 years of age, and may be regarded as under, when it will be seen that the largest number fell between the thirtieth and fiftieth years of life.

As soon as the patient is admitted to the hospital, he is well bathed and put into hospital clothes. Both eyes are thoroughly cleansed morning and evening till the day of operation, with saturated solution of boric acid, after which the affected eye is treated with atropine solution and bandaged. On the coming Saturday morning the cleansing and atropine are carried out as usual, and just before operation the cornea is anesthetized by repeated instillations of 4 per cent. cocaine hydrochlorate solution. After this, in compliance with instructions laid down by Brigade-Surgeon DRAKE BROCKMAN, the patient is laid on his back on the operating table, with his head raised and facing a window which lets in ample light. The surgeon, who should be ambidextrous, stands behind the patient's head (so as to operate on the right eye with his right hand and the left eye with the left hand) and (1) separating the lids to (2) secure the eyeball by catch-forceps in the vertical-meridian of the cornea into (3) whose anterior chamber he plunges the stop needle (Bowman's) and direct it from a point 2 mm. below the horizontal tangent of the sclero-corneal margin towards the centre of the eyeball, to pierce the anterior capsule of the lens with two punctures at right angles to each other. Very gently and slowly withdrawing the needle (4) replace it with the knife, sharp edge up, and, depressing the handle till the point is horizontal with the point of puncture, push the blade in as far as it will go without pricking the patient's nose, but cutting through the sclero-corneal margin of the cornea and finish the section very gently while withdrawing the blade. (5) If necessary, perform iridectomy. (6) Start the lens from its bed by slight pressure of the catch forceps and gently depressing the upper lip of the wound follow the escaping lens carefully with the curette, as well as stroke over the anterior surface of the cornea to clear the anterior chamber of a large quantity, if not all, of the soft cortical matter (7) Relaxing speculum to draw the lids forward, wash out the anterior surface of the eye ball and palpebral enclavure (8) over which sprinkle iodoform and removing the speculum (9) lay flat aneured with boric ointment or white vasoline over the lids of the eye operated on. (10) Apply pledgets of cotton-wool covered with (11) dry lint over both eyes and (12) bandage closely. In case of double cataract the second eye is usually operated on the Saturday following that on which the lens of the first eye was extracted.

As soon as a patient is admitted, he is well bathed and put into hospital clothes. Both eyes are thoroughly cleansed morning and evening till the day of operation, with saturated solution of boric acid, after which the affected eye is treated with atropine solution and bandaged. On the coming Saturday morning the cleansing and atropine are carried out as usual, and just before operation the cornea is anesthetized by repeated instillations of 4 per cent. cocaine hydrochlorate solution. After this, in compliance with instructions laid down by Brigade-Surgeon DRAKE BROCKMAN, the patient is laid on his back on the operating table, with his head raised and facing a window which lets in ample light. (10) Apply pledgets of cotton-wool covered with (11) dry lint over both eyes and (12) bandage closely. In case of double cataract the second eye is usually operated on the Saturday following that on which the lens of the first eye was extracted.

Classification of cataracts.—A few words are necessary,

though the little remarks in the preceding chapters, of which there are many instances, which may conveniently be classified as—(a) *Soft cataract*, which corresponds to the mixed cataract of English text-books, is a stage between the (d) soft and (f) hard cataract and is the kind most frequently met with in Southern India. The cortex, of which a portion is shown left behind after expression of the lens, is distinctly softer than the nucleus which is white (sometimes yellow or brown) opaque, not firm in consistence and is surrounded by partially opaque cortical matter; (b) *Hard cataract*, which is a hard cataract that has undergone pathological softening which usually begins in the cortical portion of the lens which becomes more or less fluid and milky-looking. In these cases, which generally yield excellent results, the lens may be removed in its capsule or its disintegrative nucleus and milky contents discharged by puncturing the capsule which can afterwards be removed by gentle traction with the curved iris forceps. This (c) hard and (d) the black cataracts, which may be drawn together, most frequently necessitate iridectomy as the lens is opaque (sometimes translucent in the black) and both cortex and nucleus are hard and inseparable, while the capsule is more often adherent to the lens, though the attachments of the lens do not seem to be so firm. (e) The soft or "lamellar" cataract of different text-books is soft throughout and, while rarely seen in natives over 38 years old, is most often met with in those who are under 18 years of age. The opaque lens is either white or bluish-white and when examined by focal illumination of the eye after full dilatation of the pupil, the capsule looks like mother-of-pearl. TRALK's suction method used to be employed by the writer who now makes it a rule, when the sufferer is over 9 or 10 years of age, to remove the lens by the method followed in dealing with cortical nuclear cataracts (f) In capsular cataracts both the nucleus and the cortex of the lens are absent, while the capsule which remains to obstruct vision by its opacity may be removed by vertical downward insertion of a large-sized keratome into the anterior chamber, and very gentle traction on the capsule with a cross-action iris forceps. (g) *Congenital cataracts*, in which the opaque lenses are essentially soft in consistence and which affect both eyes to the same extent, are usually seen between the first and seventh year of life and always necessitate chloroform and strict asepsis when breaking up the lens to render TRALK's suction method successful.

Remarks.—It is but natural for a surgeon to speak up for and seem quite satisfied with his own methods of operation, even though that method may not be free from small imperfections as well as have great room for improvement in certain directions, still the writer, who has tried all the methods he has seen and read of, prefers to stand by those methods that have given him such excellent results in the Madras Ophthalmic Hospital from May 1892 to July 1895. Thus while the majority of ophthalmic surgeons in Great Britain and on the Continent invariably perform iridectomy as a routine practice for safety sake before proceeding to expel the lens, the writer has had only 68 failures (or 3.15 per cent.) in operating on 1,815 Cortico-Nuclear, 351 Hard, 217 Morgagnian, 28 Traumatic, 25 Congenital; 13 Black, 6 Capsular

and 30 soft cataracts. He did not resort to iridectomy in more than 190 (i.e. 9.5 per cent.) of these cases, allowing 'middle class' medicine to admit that to *never* perform iridectomy is unscientific and often dangerous, but as he emphatically maintains that to *always* perform is needless and interfering, he has recourse to it only when he meets with (1) an iris that will not dilate sufficiently, (2) adhesions of the iris, (3) a bulky lens, (4) a too small corneal incision (5) a lens more firmly set than is the case, more specially in younger patients. In dealing with *Traumatic cataract* the wisest method is to adopt appropriate treatment to subdue the inflammatory condition accompanying the trauma, and then removing the injured lens either by dissection followed by TEALE'S suction or by the usual way of dealing with cortical-nuclear cataracts.

THE NATURE AND PREVENTION OF PUERPERAL FEVER.*

By THOMAS WILSON, M.D., Lond., F.R.C.S., Eng.

Assistant Obstetric Officer, General Hospital, Birmingham.

THOUGH from about B. C. 400 when HIPPOCRATES described some 8 cases sufficiently for easy recognition, there has never been any lack either of material to study this affection or of theories to account for its occurrence, still it was not till A. D. 1847, when SEMMELWEISS' affirmation of child-bed fever being due to absorption of animal putrefactive products, led to the laying down of a solid foundation for building up a true knowledge of the nature of puerperal fever. Since then PASTEUR, LISIER and KOCH, with hundreds of other observers, have added much to our knowledge by proving the relation of various organisms to many diseases, puerperal fever amongst them: so much so that though it is true that there is no appreciable alteration discernible in the incidence of the affection on the general population, and that in every 1,000 deliveries nearly three women die from this preventable disease, while for every death that occurs MANY cases of prolonged illness and suffering are traceable to the same cause, still for the last 20 years puerperal fever has been almost entirely abolished in all properly conducted lying-in hospitals.

The reason for this sad state of affairs is, that the real nature and origin of the disease is not sufficiently, if at all, understood by a large proportion of those whose business it is to attend on labors, but though as a profession we are responsible for pointing out all that should be done, the remedies are complex and difficult of application since they have to do not only with ourselves, but also with the very large body of women who habitually or at odd times act as midwives and after nurses.

There is a large amount of truth in Professor SINCLAIR'S complaint† that like the Israelites of old the teachers of midwifery have to be content to continue to make bricks without straw by loading the student with precepts only, where example is most needed to give the skill to enable him to carry these precepts into safe and effective practice, and that while particular attention is paid to surgery, which will not form much of their work, our students are

not taught midwifery which will form a very large part of it. Experience to be of any practical value must be built on a secure foundation of obstetric knowledge well and truly implanted in our students; but it is impossible for that foundation to be truly laid so long as the practical instruction is carried out in the imperfect and slipshod manner, which generally obtains at present, and it is discreditable that in a big city like Birmingham, with "Forward" for its motto, there is no lying-in hospital where efficient instruction can be given to nurses and pupils, in the proper method of examining or conducting a labor case in the application of antiseptic principles and in the treatment of the various complications that may arise. Under this backward state of affairs it all the more behooves us, as practitioners, to compare notes from time to time and to consider how far our opinions and practice are in accordance with the latest advances in knowledge.

Of the whole number of cases in which there is rise of temperature after delivery, about one-third are *not* due to affections of the genital canal, and a large proportion of these is due to affections of the breasts and nipples. But as the remaining two-thirds which do constitute puerperal fever, properly so-called, are due to microbic infection of the genital canal, we have to consider (1) what are the organisms or microbes that are concerned, (2) whence their source, (3) how they affect the patient, and (4) how the infection may be prevented.

I. *The organisms concerned* in puerperal infection belong in the majority of cases to three sets of microbes—(1) the pyogenic cocci, specially the streptococcus pyogenes and the staphylococcus pyogenes aureus; (2) the gonococcus, and (3) putrefactive organisms. These three classes vary in the severity of the symptoms they produce. In the streptococci cases, which are most severe and the most frequently fatal, there is usually excessive loss of blood. The gonococcus cases are less severe but frequently very persistent, while the discharges are markedly purulent, and the putrefactive cases which are the most amenable to treatment are accompanied by stinking discharges. Thus of 179 cases of puerperal endometritis investigated by KNOWN of Leipzig, 75 were caused by the streptococcus pyogenes, 4 by the staphylococcus pyogenes aureus, 50 by the gonococcus and 50 by putrefactive organisms. Besides those above enumerated there are other organisms which less commonly produce puerperal infection, and of these the bacterium coli commune and the streptococcus of erysipelas are the most frequent and the most important. Scarlet fever "breeds true" in the puerperal patient; but as scarlet fever is frequently complicated by pyogenic cocci, it is easy to see how from such a case true puerperal infection may arise, and the diphtheria organism may very exceptionally invade the injured vulva and vagina of the puerperal woman.

II. *Whence are these organisms derived?*—Nothing is definitely known beyond that everything that surrounds the patient, whether walls, furniture, clothing, platter, food, water or air and even her friend, the entire body literally teems with countless herds of micro-organisms of numer-

* Read before the Midland Medical Society and specially reported for the *Indian Medical Record*.

† *British Medical Journal*, II, 1897, page 889.

*Cent Sur Gynak, No 16, 1896, page 492. Atiologic and Therapie der puerperalen endometritis.

From the mouth of the urethra, coming from the epithelium and mucous membrane, and extending to the mouth of the urethra, numerous glands are found, the roots of which are situated in the skin, which are kept moist and warm, and especially when the parts are not kept clean, become a fertile source of infection, and find a favorite place for breeding and preservation in the vagina, whence they spread to the vagina, in the lower part of which they are plentiful, but they grow less numerous as this tube ascends, till they are found wanting in the upper part of the cervical canal, and are utterly absent in the cavity of the uterus, and in the Fallopian tubes. The rectum and its contents are another source of microbes, which may easily infect broken surfaces of the vagina or uterus, or be carried higher up by the examining finger. Unless they have been sterilized or disinfected just prior to use, instruments, napkins, towels, swabs and the like which are brought in contact with the parts concerned are also fertile sources of danger, while the danger of sheets, blankets, making tables and bed furniture infecting the hands or any instruments brought in contact with them may be avoided by surrounding the field of action with clean towels, but the most important sources of infection for a patient and yet the most difficult to render safe and clean are the hands of her doctor and nurse.

III. *How do the germs affect the patient?*—(1) Idiocy-nary, (2) duration of the labor from first pains to actual delivery, (3) the amount of blood lost, (4) and any thing that tends to lower the strength and vitality of the patient predisposes her to the invasion of pathogenic germs whose multiple injurious effects may be briefed into two groups: (1) Those acting only on dead tissues and fluids begin their work by setting up unhealthy inflammatory processes locally through acting on (a) the surface of vaginal and cervical wounds and tears, (b) the dead layer of decidua and (c) the fluid contents of the uterus and vagina, to which follows a poisonous chemical body which is absorbed directly or through the lymphatics into the circulation in such amounts; (2) Others acting on living tissues follow the uterine and vaginal walls through and beyond

[illegible]

Clearly the different effects of the virus can be classified as (1) influenza in the case of the healthy or in their neighborhood, (2) epidemic, (3) pandemic, (4) pandemic. It is fortunate that in some cases, even in the conditions as far as considered as pandemic, the disease still escapes without any harm, but in many cases it is a matter of life and death, often so slight as to escape notice at the time, and not a few of them "lighten" diff into a condition of chronic disease making the patient suffer more or less for months or years.

IV. *Provenient treatment*, which is the goal of medical science, has two equally important indications:—(1) Preserving the strength of the patient by the correct management of pregnancy and labor from beginning to end, so that her body and mind may be in as favorable a condition as will enable her to resist infection. This may be effected by (a) a suitable and nutritious diet that will keep her bowels properly regulated, (b) warm or comfortable and clean sitting but not tight clothing, (c) gentle exercises all through pregnancy, (d) pleasant company to enliven her and keep her mind free from excitement or morbid anxieties, and (e) strict exclusion from her company during pregnancy, but more particularly after labor has begun, of those pernicious know-all gossips who infect every thing in reach they can get admittance to; for nothing harms the parturient woman more than having to listen to the exaggerated and often lying tales of suffering and death in which these harpies revel. (2) To avoid infection of the patient by (a) keeping the passages, as far as possible, clear of putrescible matters such as blood-clots, discharges &c. and (b) avoiding introducing germs from without, during the necessary examinations and manipulations.

The care of the hands is of prime importance to the doctor and nurse, since either or both of them have to daily do with boils, acute abscesses, ulcers of all descriptions, carbuncles, putrefying cancers and innumerable other septic cases with which their hands must necessarily come more or less intimately into contact, and as the hands are the most fertile carriers of disease germs from without to the patient, women, too much care cannot be taken in rendering the hands germ-free, as far as possible. For this purpose, the nails should be kept fairly short with the furrows under their free edge cleaned with a blunt knife and the ingrowth of skin over the lunule pushed back. When about to be used for obstetric or surgical purposes, the (a) hands, (b) forearms, and (c) the furrows under and round the nails are vigorously scrubbed for three minutes with a nail brush and hot water and soap. (d) The ends of these parts are vigorously rubbed with a wool-wool dipped in spirit, ether or turpentine, after which (e) they are scrubbed for two minutes with a brush and 1 in 20 carbolic solution or a 1 per mille salicylic solution, but not dried by wiping. If the hands become tender or irritate, soak them well with glycerine before each washing in soap and water. In gristled labor or especially

dangerous cases, the whole process of washing the hands should be repeated two or three times at intervals of a few hours.

The routine use of vaginal douches probably does harm if administered during labor by washing away the abundant genitoid mucous which is then secreted, and leading to a dry, hymen condition of the walls of the passages, predisposing them to fissures and ruptures; but in the early part of the first stage of labor a douche is least likely to do harm; while it is of decided value, both in preventing infection of the patient during labor as well as guarding the infant against ophthalmia when coming down the genital canal of a mother who is suffering from pathological discharges, and more especially are douches necessary when the discharge is known to be gonorrhoeal. At the conclusion of such labors as well as of those where repeated vaginal examinations or operative measures such as forceps, craniotomy, version, manual removal of placenta, &c. have had to be employed, an efficient douche should be given of one part of corrosive sublimate in 2000 parts of water as hot as the hand can possibly bear.

Abdominal versus vaginal examinations is pleaded by some persons. True that by the abdominal methods, which are more easy to learn than the vaginal, the position, relations and vitality of the child, the presentation, the character, duration and frequency of the pains and the external measurements of the pelvis can all be made out; but the condition of the cervix, os uteri and the soft parts of the parturient canal, and the relation to these of the bag of membranes and the presenting part can be revealed only by vaginal exploration, which should be limited as far as is consistent with gaining a sufficient knowledge of the progress of labor as repeated examinations, specially when prolonged, can only be harmful. But in any case before each and every examination care must be taken that the hands are carefully cleansed by washing.

Treatment before, during and after labor is divided into five portions.—(1) *Preliminary*. Throughout pregnancy the external organs should be scoured daily with soap and water. Sponges should not be used in pudendal ablutions, but in their stead pads of wool or tow that can be burnt. Women with pathological discharges should have warm vaginal douches daily for two to three weeks before labor. (2) *First stage of labor*.—As soon as labor begins, the lower bowel should be evacuated by a two-pint enema of warm soap-suds. After which the vulva should be carefully cleared, the hair of the labia cut short and the whole region, including the mons veneris and inside of the thighs should be cleansed thoroughly by the processes described under "care of the hands" and the cleansed woman put into clean clothes, the underlinen being fresh from the laundry. (3) *Second stage*.—Make a vaginal examination when the membranes rupture, and if all be found normal on abdominal palpation, the duration of the interval between the pains and the maternal pulse between the pains are sufficient indices. The timely use of the forceps prevents exhaustion; but never hurry. Support the perineum with a clean napkin to prevent laceration as far as possible, when the head comes down at the end of this second stage carefully examine the perineum and immediately suture any tears with silk-worm gut so as to

prevent post-partum infection or subsequent pelvic trouble. (4) In the third stage efforts are directed to secure good and complete contraction of the uterus after seeing that no portion of the placenta or membranes is left behind. Where numerous internal examinations or operative measures have been undertaken (not only a warm antiseptic douche should be given. Finally, an abdominal binder is applied. (5) In the puerperium great care should be taken to twice daily cleanse the external organs by a swab dipped in Condy's fluid, boracic acid, iodine or other antiseptic solution. The routine use of douches is unnecessary and sometimes harmful, and syringing should only be ordered in the presence of pathological germs. The best materials being iodine water (i.e., Linctament Iodii 3j, aqua 3i.) or dilute Condy's fluid; but in any case the medical attendant should himself administer the injections, unless he can absolutely rely on the care and efficiency of the nurse.

IS EVE STILL TO BLAME?

BY JAMES LENOX BROWN.

Bombay.

LOOKER, in his valuable essay on the human understanding, has endeavoured to prove that there is no such thing as innate ideas, and that all our ideas are brought to us from without by our five senses.

That this is so there is no doubt.

We look upon the world as we see it, and form certain ideas of everything we see, as to whether it is round, square, flat, oblong, shapeless, hideous, pretty, dull, or bright. We hear a sound and form some conception as to whether it is melodious or dissonant, soft or harsh, low or loud. We perceive a smell and form at once some ideas as to its character, whether it is stifling or invigorating, irritating or soothing, inodorous or fragrant. We taste something and form at once an idea as to whether it is sweet or bitter, mild or acrid. We touch something and form some conception as to its hardness or softness, roughness or greasiness, dryness or moistness. All just as each one of us may separately imagine.

By such means all our ideas are brought to us. We begin to think, compare, judge, classify and act; we form our associations and begin to consider as to whether this man or that man is good or bad, or as to whether this action or that action is right or wrong; and, so, by our associations, by our thoughts, and by our actions, we either show ourselves to be men indeed or devils incarnate.

So far, so good. Certain reasons and certain principles, formed by our conception of things as they may appear to each one of us, control all our actions, but deep down within the depths of our inmost being, there might be just a spark of some sort of principle around which all other reasons and principles have gathered, which, like a spark below a heap of debris that has accumulated above it, may at any moment burst into flame and consume all.

In considering the extent to which all our ideas are brought to us from without through the media of our senses, we look upon man as he is from the day when first he breathes the life-giving properties of our atmosphere, to the day when he ceases to breathe for ever; and, in so doing, we omit to consider the impressions that are formed

upon the soft and pliant little mind while he is still in his pre-natal state—depression, or, at least, a leaning; that the accumulated teachings of years, if contrary to those ingrained, would, no more succeed in directing them, than a mass of rubbish would in smothering the smouldering fire above which it is recklessly heaped.

There are two sides to this question which we must consider.

There are men, who behave like men, merely through the sheer force of circumstances. From their earliest infancy they are brought up amidst the best of surroundings, in their youth their kind fathers spare no pains in reproving them by chastisement; and, when these enter upon their manhood, their loving parents omit not to place them under the watchful care of honest and straight forward patrons—men of the world, who have seen the world, and are only too ready to seize every opportunity of keeping young men from going astray. Such young men then, moving amidst respectable surroundings, with their watchful patrons for ever secretly inquiring after their mode of life, would be deterred from misconducting themselves in any way by a consciousness of the overpowering sense of shame which they wisely foresee would seize them were they so to do; yet such men may yet be possessed of a principle of evil fiendish in the extreme—a principle of evil suppressed under the great weight of conventionality and suppressed so long as the eye of their patron is upon them, but allowed to assert itself when conventionality and patronage are both out of sight or suspended.

On the contrary, there are men who are not men in their ways, but bears—men bearing a strong relation to civilised savages. Brought up from their infancy amidst the worst of surroundings, knocked and buffeted about in their youth, alternately spanked and petted by their parents, and perhaps entirely spoilt, and at last turned out upon a heartless world to go and earn their own living, alone and unbefriended, and to learn the ways of men and things, with none but their own bewildered selves to guide them aright,—such men may yet have a sterling quality of goodness hidden far down in the depths of their rugged natures, which will more than equal in value the forcibly assumed merits of the former class—but goodness that has been smothered, smothered by the oppressive circumstances of their existence.

Why should this be so? Looking at the whole Christian world—God pardon the apparent narrow-mindedness—in the light of one large family, with God Almighty as its Father, why should so many of its prodigal sons repent of their evil ways and return to their Father's fold to be truer and better men for the future, and why should so many of their brothers who had remained at home and were constantly under the watchful care of their guardian parent, give expression to such fiendish hatred towards their spendthrift brothers on their return!

The answer is brief and simple. 'Twas but the inborn spirit,—the spirit that had been infused into each one of them, while they were being rocked in the cradle of the womb!

Mother, take heed to what I say: Your children will be children indeed to you if from the time of the conception of each one of them to the time of its birth your

thoughts, words, and deeds are holy. On your life depends the salvation of the souls of men.

That maternity's thoughts, during the period of pregnancy, have a great deal to do with the future child's state of mind there can be no doubt. The greatest gentleness of this world have acquired their gentleness solely from their mothers, their fathers having nothing whatever to do with it. Fathers are like sowers, the product of whose sowings depend largely upon the various soils upon which they sow, whether rich or poor.

One notable instance that may have struck many of us, is to see a learned man with a stupid son as his father's heir.

To wit, HUGO ARAM, one of whose sons was a drivelling idiot. For this of course the mother is to be held responsible.

All this however concerns the effect that the general or normal disposition of the mother's mind may have upon that of her child's. What about those cases in which some peculiar trait of character most unaccountably manifests itself in one of the children, while the rest of the children show not the faintest traces of that trait? Take a notable example. The brothers and sisters of INGHAM, the well-known atheist, are all stalwart Christians, but INGHAM himself is utterly deficient in this ability. Why? The story runs that while INGHAM was still in his pre-natal state, his mother read with avidity the works of VOLTAIRE. The result was that when INGHAM came into the world, he grew up to be as philosophically atheistical as VOLTAIRE, and no amount of Christian education in his youth was sufficiently strong enough to overcome the atheistical convictions that were grafted upon his pliant little mind while he was still in his pre-natal state.

In one of his interesting essays, Sir RICHARD STEELE gives us an instance of a striking contrast that existed between the characters of two sons, the father of whom is supposed to have communicated the information to STEELE in a letter. Here are his words:—"If this winter should prove as severe as the last, I can tell you beforehand that I am likely to be a very miserable man, through the perverse temper of my eldest boy. When the frost was in its extremity, you must know that most of the black-birds, robins and finches of the parish, whose music has entertained me in the summer, took refuge under my roof. Upon this my care was to rise every morning before day to set open my windows for the reception of the cold and hungry whom at the same time I relieved with a very plentiful alms, by strewing corn and seeds upon the floors and shelves. But DICKY, without any regard to the laws of hospitality, considered the ornaments as so many traps, and used every bird as a prisoner at discretion. Never did tyrant exercise more various cruelties. Some of the poor creatures he chased to death about the room; others he drove into the jaws of a blood-thirsty cat; and even in his greatest acts of mercy either clipped the wings or singed the tails of his innocent captives. You will laugh when I tell you I sympathised with every bird in his misfortunes, but I believe you will think me in the right for bewailing the child's unlucky humour. On the other hand, I am extremely pleased to see his younger brother carry a universal benevolence towards everything that has life. When he was between four and five years old, I caught him weeping over a beautiful butterfly which he chanced

"Gentlemen, your education is not finished. It is a mistake to suppose that one's education is complete when one leaves the College. It is your general education alone that is now complete, but self and practical education has to be gone through all life. Make it a point to know what you have learnt. Certain amount of knowledge you have acquired and your powers, both of reason and judgment have, to a certain extent, been developed and your mind trained. Your stock of knowledge must be gradually increased to a great extent, your mental faculties must be further improved and strengthened by constant exercise. The principles of morality that have been instilled into you must be so observed as to make your conduct in life useful and honorable.

To do all this, it will take a long time, but life is short. Your success will depend greatly upon how your time is spent. There are certain things whereon we have to spend time which are quite essential, such as exercise, recreation and rest. But to devote your precious time to frivolities and useless topics is sheer waste of time. Do not devote the greater part of your time to objects irrelevant to your calling in life.

Gentlemen, as you are now stepping into the world, it is of importance that you should have an idea of the principle objects you have to achieve in life. These are of two kinds, viz., material and moral happiness to yourselves and material and moral happiness to others. To attain these, you must have knowledge and virtue which, I believe, you have to a certain extent acquired as certified by your lecturers and examiners. Increase them by diligent and well directed self-education and promote them to the best of your ability.

In doing so, do not over-stretch your capabilities, nor attempt to do anything that you are unable to do, for if you should, your professional career will be obstructed and no matter how able you are, failure and consequent disappointment will be your end.

One of the essential ingredients that go to form success in life is good manners. It is acquired by a little study and a little observation. Good manners are to life what oil is to machinery, as they tend materially to diminish the friction which attends the passage of life.

In the course of your life, you may come across good, bad and indifferent men. Take good care not to wound their feelings needlessly. Avoid harsh and unpleasant words, but always express yourselves truthfully, taking into consideration the excellence of the wholesome adage "Truth is great and must prevail."

Be independent. Independence does not consist in claiming equality with your superiors—official and social—nor in holding a tight rein over your inferiors. Obedience is not incompatible with independence. Cheerfully obey your superiors, albeit they owe their position to accident, to age, to interest, to wealth, nay, even to desert. They are above you, and it will be your duty to recognize them accordingly and show them the deference due to their position. There is an old and true saying which you must always keep in mind, "He knows to command who knows to obey."

Whatever you do, do it with all your might. Never undertake to do a thing wherein you cannot hope to suc-

ceed. But once you set to it, try, try, and try again till you achieve the desired object. But, if, perchance, you fail, having done your duty to your utmost there will be no disgrace.

When after due enquiry and thought you have reached a useful conviction, avow it without fear or favor. By so doing, you will materially accelerate the progress and propagation of the truth, so essential a factor for public improvement. You can go a step further by acting upon them as far as practicable.

The profession.—Having given you some general advice, I shall next proceed to say a few words connected with the profession.

Gentlemen, you have become members of a noble profession—a profession which is second to none in point of dignity. To take up any profession and to be of use to one's fellow beings, it is essential that one should enjoy good health. "Health is the vital principle of life." An idler too must have sound health even to enjoy the pleasures of the world. The health of the people is in the hands of our profession, both in its curative and preventative branches. We are, in fact, the custodians of public health.

Man is endowed with five sentiments, and he rightly takes pride in assiduously cultivating them. Can you name another profession which sharpens your feelings and keeps you more in touch with misery? Be true to the principle "Do unto others as you would be done by." We do our duty by the bed-side of the patient, ministering to his wants and putting up with things which repel even his nearest relations. Nay, by cheerfully undertaking to work among people afflicted with plague, cholera and other infectious diseases, we willingly risk our lives at the altar of suffering humanity. All these points place the medical profession on a much higher level than the rest. Such, gentlemen, is the nature of the profession you have joined. If you honestly follow this walk of life and act up to the best traditions of the profession, rest assured that you will achieve as much success in the world as any member of any other profession. If the world has distinguished statesmen, eminent lawyers and renowned engineers and artists, it has also got its Lord LISTER and its Sir JAMES PAGET and only lately it has lost its Sir ANDREW CLARKE and Professor CHABOOT, who have held their own against others in the battle of life as regards the acquisition of honor, dignity and wealth. They are the embodiments of all that is good and great in our profession, and I exhort you to follow their example as far as possible.

Theory and practice.—Combine experience with knowledge. Knowledge is of two kinds: theoretical and practical. The former is what you learn from books; the latter is what you gain by experience. In all that you do, combine practice with theory. The latter devoid of the former is of no use. Many a man may know the theory of navigation, but very few make good mariners. You have hitherto acquired a theoretical knowledge; the practical side of it you have yet to learn. You may be acquainted with the use of every drug in the pharmacopoeia and know the therapeutic action of the same, you may know the etiology and symptoms of every disease; but the first time you are taken to a sick-bed

and that is, to bring the student down to the level of the public pulse and the inherent weakness of the patient; the chances are a hundred to one that you are wrong. Science does not consist in superior theoretical knowledge, but in the intuitive skill with which that knowledge is adapted to new states of facts. This can only be acquired by patient study and realities of life. Book-reading, however wide, can give you only half your education; the remainder must be acquired by practice.

Qualities of a medical man.—A combination of practical and theoretical knowledge is one of the many qualifications required in a medical man. His situation is one of the most delicate and confidential. Perfect uprightness, moral courage, kindness of heart and demeanour, and above all, a readiness to sacrifice personal comfort are all required to be united with knowledge to make a genuine member of your profession. Cultivate patience, care, diligence, promptitude and punctuality. Want of patience will lead to wrong diagnosis, and want of care to danger to the sick person's life.

Duties and responsibilities of a medical man.—Added to all these qualifications, you have certain duties and responsibilities to perform. Unlike men of other professions, the duties and responsibilities of a medical man are unique in their character. Medical men have no Acts to bind them together. It is therefore all the more necessary that they should make a bond of honor. Gentlemen, in your calling, voluntary obligations take the place of legal. You will not have only to look to a distinguished name and for the momentary rewards that may follow upon such a reputation. Take, for instance, a case in which you, as medical adviser enter a sick chamber to examine the state of your patient; see that patient's mother watching you every moment, hanging breathless upon the words that are about to fall from your lips, see also the other members of the family partially ignorant perhaps of the condition of the patient, but looking upon you with silent awe! Now, after careful examination, observe the visitors' cheerful eye anticipating your mouth in the announcement that the patient is out of all danger; and watch the silent but expressive gratitude of the whole family, surely, the power thus to ease the over-strained heart is one of the most delightful possessions that a man can have. Can any compensation be richer and more pleasant than the gratitude of a mother?

A few words of advice to the Civil Pupils.—Gentlemen belonging to the civil service, most of you may be posted to independent charge of dispensaries, when will devolve upon you the most important duty of popularizing English medicine among ignorant villagers. You may become chairmen and members of village unions, taluka, district and municipal boards. In such capacities, you will be the pioneers of sanitation in remote rural areas, and I trust you will use the advantage of such positions in furthering the health of the people.

You may constantly have to deal with medico-legal cases, in connection with which you will have to appear before the courts when your general knowledge of all subjects will be put to a severe test. As you may have to deal with lawyers and the police, I would suggest that you may advantageously go through the Indian Penal Code. Above all, there may be many temptations in these cases

to bend your energy, but you must stand firm and stick to all by keeping your heads clear.

Military pupils.—You, too, are going to serve in the army, I cannot sufficiently impress upon you the necessity for observing strict discipline. However unreasonably the order of your superior may seem to you, first obey it and then represent your grievances. Remember the fate of the Assistant Surgeon who was lately degraded for refusing to do what he considered to be no part of his duty. Acquaint yourselves with all military rules. Since there is not much scope for practice in the army, make up your deficiency by always reading reported cases. Bear in mind that you have to work side by side with the soldiers, and it will be well if you try to acquire all soldierly virtues that you may serve your Queen and your country with honor and glory.

Ladies.—Last, though not least, to you I will say your work lies among Goshia women who are only too willing to welcome you in preference to men. It is with the object of providing medical aid to menama women, that Lady Duffarin has founded a fund to encourage women to take up the medical profession. We, men, are quite willing to give you equal rights with us. The Madras Medical College levies no fees from you, I am glad that so many of you have availed yourselves of these opportunities, and trust that you will grace the profession in larger numbers in future.

General advice to all.—To all of you, I would say, uphold the dignity of your profession wherever you may chance to go or among whatever people you may happen to move. Any slight drawback or neglect evinced by you in the discharge of your duties will not only render you unhappy and unpopular, but also mar your progress in life and lower you in the estimation of the public at large. The most important part of your duties—and one beset with great responsibilities—is the examination of dead bodies and carcases, and granting of certificates in connection therewith and the giving of evidence before the magistrates and session courts. In this connection I must tell you, gentlemen, that the greatest caution and care should be taken in forming your opinion as to the nature and cause of death or injury, and such opinion must be fully based upon the post-mortem appearances as they present themselves before you. Since you will not be the eye-witnesses to the incidents under reference, you should not adhere to one opinion if two causes can bring about the same result from a medico-legal point of view. The greatest precaution is in this case absolutely necessary, as the life and death of many an innocent citizen may depend on the opinion you hazard.

Gentlemen, I think I am taxing your patience. One word more and I shall be done. In this my humble address, I have endeavoured to give you an idea of your duties towards mankind. But there yet remains the pleasing duty of exhorting you all to love the Almighty Creator of the universe to whose benign and tender care we all owe our existence. Love of God must be the crowning motto of all your actions, and act as a charm to all that you say or do.

There now remains for me, gentlemen, to bid you all a hearty farewell. Therefore with a fervent prayer

the patient's discharge from duty, which had in his confidence, been ordered for you, I tell you all go forth and try to win your spurs in the battle of life.

In conclusion, I beg to thank you gentlemen, for the patient hearing you have accorded to me and the honor you have done me in asking me to read the address.

10: NASAL POLYPI.*

By H. J. DARTMUT, L.R.C.P., L.R.C.S. (Edin.), L.F.P.S. (Glas.)

Fellow of the British Laryngological, Rhinological and Otolological Society of London; Consulting Aural Surgeon to the Church-gate and Wandri Medical and Surgical Halls, Bombay.

Nasal polypi are usually pale-yellowish colored, soft jelly-like, pear-shaped tumours of various sizes—from a pea to a plum in size—that grow in the nasal passages. Sometimes they are of a translucent bluish-gray color and their shape may be altered by the pressure they exert on one another, or receive from the nasal wall. They weigh from 30 to 260 grains, and are less common in females than in males, whom they rarely affect before the age of 15 years, and most usually after the twentieth year of life. Their favorite seat is the mucous membrane lining the meatus semilunaris, and they usually take their origin from the middle or superior turbinals on the outer wall of the middle meatus, but they occasionally spring from the inferior turbinal, and there are instances where the polypus has grown from the septum nasi or has been found in accessory cavities, notably of the antrum.

They generally commence in one nostril and spread to the other, and patients who complain of unilateral obstruction at first are unconscious of the co-existence of polypus in the other nostril, until the obstruction they first noticed is removed.

Etiology.—Though there is no well-defined theory of causation, it is generally held that chronic nasal catarrh is the chief source of nasal polypi which may be (a) benign, innocent or non-malignant, or (b) malignant. To the former belong the mucous, fibromatous, cystomatous and papillomatous forms, while to the latter class are assigned scirrhus, carcinomata and sarcomata.

Dr. BOEWORTH of New York advances two theories: (1) Chronic catarrh waterlogs the mucous covering of the middle turbinal area and anterior stenosis and the suction action of hawking, sniffing or blowing the nose accounts for the pyriform growth of nasal polypi, (2) mucoid degeneration primarily occurs in the ethmoid cells, and as the secretions increase in amount, they are squeezed out in the polypoid form much as honey does when pressed out of a honeycomb. Professor LEMAX BROWN inclines to these beliefs, but adds that the pedunculization is rather due to the force of gravity than to hawking or blowing the nose; but Mr. DONELL MACKENZIE, who does not however state his own views as to real causation, declines to accept catarrh as an etiological factor, since polypi rarely occurs between infancy and puberty, when catarrh is common enough.

* Read before the General College Medical Society and sent by the author for publication in the Indian Medical Record.

Professor MACKENZIE, of Edinburgh, believes that cedema of the middle turbinal space diminishes the resistance of the mucous membrane at certain places where projections appear. The force of gravity aided by suction of the respiratory current makes the projected parts more cedematous and therefore larger and more and more dependent; but though he allows that chronic catarrh might do something towards it, Professor GAYE, of Amsterdam, thinks that irregular septum, habitual mouth breathing and climatic influences have a bearing on the etiology of nasal polypi, which he has also known to have been originated by fetid excreta, rhinoliths and empyemata of the accessory cavities.

Dr. LEO, of Paris, finds that many of the growths are of spontaneous origin, but chronic catarrh and bone lesions are only occasional causes, while myxomatous degeneration of the folds of the mucosa is an etiological factor in nasal polypi, which Professor ZENKKE KANDAL of Kenna declares are not really neoplasms, but are inflammatory hypertrophies due to a chronic local inflammation since (1) they constantly hold round celled infiltrations without (2) a sharp line between polypi and normal tissue, and (3) tending to recur (4) are not congenital, though (5) polypoid hypertrophies may develop into polypi which (6) may also be caused by a rhinolith and (7) by inflammatory changes at the base.

Having personally known of a Persian who with his sons and grandsons suffered from mucous polypi while the whole family were peculiarly susceptible to constant nasal catarrh, the writer is of opinion that hereditary proclivity should also be considered as an etiological factor.

Symptoms, which are generally bilateral and vary with the size and location of the tumour, are partial or complete nasal stenosis, fulness and stuffy feeling in nostrils with difficulty in breathing, constant oozing of a thin watery discharge from nostrils, partial or complete loss of smell and hearing, sneezing sometimes, headache, sometime asthma and reflex cough, voice loses its tone or pitch; but with the removal of the obstruction all these reflex symptoms disappear.

Morbid Anatomy and Pathology.—The mucous polypi consist of a loose form of connective tissue whose meshes are filled with stellate cells and a mucus-yielding substance. Later on secondary changes of the cells occur and the areolar tissues become infiltrated with mucous fluids. In some cases the liquefaction of the myxomatous tissues leads to cystic degenerations, while in other cases veins and lymphatics are seen coursing over it, but which are generally strangulated at the peduncle; Hence the excessive hemorrhages and the tendency to recurrence when peduncular attachments have not been completely obliterated.

Treatment.—Astringents, escharotics and even tapping afford but temporary relief, and the best method is extirpation of the growths by knife, cautery and electric cautery, for which the way may be paved by use of albolene cocaine oil spray. Particular care being taken to prevent recurrence by completely removing the peduncle and maintaining the socket or point of origin with chromic acid or the galvanic cautery.

A MIRROR OF PRACTICE.

CONCUSSION AND COMPRESSION OF THE BRAIN : HEMIPLEGIA : REMOVAL OF THE CAUSE OF COMPRESSION : RECOVERY.

BY RAM LALL BHOWAL, C.M.S.

Camp Line Line, Anglo-Chinese Boundary Commission.

KANYA SINGH, a Hindoo male, aged about 28 years, was admitted into the Civil Hospital of Bhamo on the 25th December 1894, for lacerated and incised wounds on the head.

The patient was a subordinate jail warder in the Bhamo Jail. His wounds were the result of an outbreak among the prisoners; the man, who was on duty at the time being struck most unmercifully on the head with a mamoty (an iron tool used for digging earth). On my arrival the patient was semi-conscious and bleeding profusely from the head. The wounds were bandaged up hastily and the man removed to the hospital.

The wounds were as follow :—

1. Lacerated wound on the vertex of head $1\frac{1}{2}$ inch long, $\frac{1}{2}$ inch broad, and extending down to the bone (not fractured).

2. $\frac{3}{4}$ inch behind the above. (a) A lacerated wound $1\frac{1}{2}$ inch long, $\frac{1}{2}$ inch broad, bone fractured. (b) A lacerated wound joining above to the left $1\frac{1}{2}$ inch long, $\frac{1}{2}$ inch broad, and down to the bone (not fractured).

3. Lacerated wound on the vertex of head, left side (a) $1\frac{1}{2}$ inch long, $\frac{1}{2}$ inch broad, bone exposed but not fractured.

4. One lacerated wound on the back of head (a) $1\frac{1}{2}$ inch long, $\frac{1}{2}$ inch broad, bone exposed but not fractured. (b) Joining it on the right was a lacerated wound $\frac{1}{2}$ inch long, and $\frac{1}{2}$ inch broad.

5. One incised wound at the outer angle of right eye, $\frac{1}{2}$ inch long, $\frac{1}{2}$ inch broad, and $\frac{1}{2}$ inch deep.

The wounds were cleaned and dressed antiseptically. For the first few days there were some slight febrile symptoms, but these disappeared. He progressed well and the patient's general health improved. At the end of the first week of January, he seemed quite well with the exception of one or two wounds which had not quite healed. On the 8th January, nausea and vomiting suddenly ensued, the patient complained of giddiness and of pain in the head and right extremities, he looked stupid and dull; temperature 99°F .

9th.—Hemiplegia of right upper and lower extremities with facial paralysis of the same side. Bowels constipated and urine retained. Unable to answer any question properly. Right pupil somewhat dilated, bowels opened by enema and bladder emptied by a catheter. Pot. Iodide and Pot. Bromide combined were given internally. Galvanism was applied to the paralysed limbs.

10th.—Patient in a semi-conscious condition was carried to the operation table and a nominal dose of chloroform was administered. A crucial incision was made over wound No. 2 (a), and the fractured spot made visible. A very small piece of bone, about $\frac{1}{2}$ inch long and $\frac{1}{2}$ inch broad, was found pressing on the brain through the

flange caused by the fracture. This piece of bone was removed by a fine pair of forceps. The wound was closed by bringing the edges of the flaps together and dressed with lint soaked in carbolic lotion 1 in 40. No suture was applied.

11th and 12th.—No fever, doing well, bowels opened and urine passed by catheter.

13th.—Temperature normal, feels giddy, urine passed voluntarily.

14th.—Patient semi-conscious. Temperature morning and evening 95°F .

15th.—All wounds except No. 2 (a) have healed.

22nd.—He can lift his forearm and leg freely, but foot is swollen and painful, abscess forming on the palmar aspect. Temperature 6 A.M. 98°F and 6 P.M. 100.4°F .

23rd.—Abscess deep-seated; about an ounce of pus evacuated by incision, paralysed limbs can flex and extend at will, slight pain in head. Temperature 8 A.M. 98°F and 6 P.M. 101.4°F .

24th.—Temperature morning 99°F . Pain in foot less, evening temperature 100.4°F .

25th.—Pain in the sole of foot. Incision made near the big toe and a little pus removed. Temperature 6 P.M. 101.4 .

26th.—Progressing favorably. Temperature normal.

4th & 5th Feb.—Doing well, wound of head healing rapidly. Abscess of foot nearly well, no pain.

18th Feb.—Abscess of foot well, but complains of pain in the foot.

Patient was discharged completely cured at the end of the first week of March, 1895.

I have to thank Dr. J. DOBRY, the Civil Surgeon, who very efficiently performed the operation, and under whom I attended the case.

—:—:—

A TYPICAL CASE OF INFANTILE CONVULSIONS.

BY ASSISTANT SURGEON M. A. CURRY, D.G.M.C.

Nussacabad.

On the 11th of December 1897, I was suddenly summoned to see a private case in the bazaar. On my arrival at the house at 9 A.M. I found the patient was a Parsee child of about two months old. The father being a rather intelligent man, I elicited the following information on inquiry.

It appeared that he had previously lost three children varying between the ages of two and three months from convulsions, which were treated by practitioners in Bombay, but all died in from two to twenty-four hours. This made him very anxious about this child.

On examination, I found the infant was fairly developed was suffering from convulsions which were more or less general in character.

The symptoms of an attack were the following :—

Carpus-pedal twitchings, the legs were drawn up to its belly, pupils dilated, the head hot and the fontanelle prominent, pulse quick and small, the abdomen puffed, vomiting and slight feverishness. This was the first paroxysm I saw and lasted about two minutes. The child was being weaned as the mother had hardly any milk in her breasts. On inquiry regarding the child's nourishment I learnt it was being fed on equal parts of tea and milk. The bowels were always very constipated.

The patient was given a hot bath every day and then at longer intervals. It seemed to have an immediate beneficial effect on the convulsions. A purgative of Pulvis Rhei Co. and Calomel was given, and a mixture of syrupus Chloral Hydrat, Potassi Bromidat, Spiritus Chloroformi and Aqua Camphorae every half hour. It was kept on milk mixed with equal parts of water, cold water mixed with Eau-de-Cologne was kept constantly applied to the head. The convulsions gradually diminished in their severity and frequency with this treatment on the first day.

On the second day I discontinued the hot baths and repeated the other treatment. Another purgative was administered as the bowels were very obstinate. The mixture was continued every second hour. On the evening of the third day the convulsions ceased. I then stopped all the treatment on the fourth day and ordered a few drops of brandy to be given with milk. The infant improved rapidly, and is now thriving very well.

Remarks.—I may add a few words of interest with reference to such cases. In some cases of convulsions it is often very difficult to discover the cause which it is always very important to know before attempting any particular line of treatment, and as the mortality from this disease is generally very high, more attention should be paid to this fact. In this case there was undoubtedly cerebral congestion present, but the ultimate cause of the congestion was difficult to account for. I am of opinion that rickets in many cases account for convulsions, though there were no evident signs whatever present in this case, and I fully believe that the symptoms were latent. Hereditary rickets apparently derived from the mother's side, aided by improper food and bad ventilation, were the only probable causes.

CASE OF ACUTE ANTERIOR POLIOMYELITIS.

By V. DINNIAW, G.H.M.S.

Medical Officer, Chanchol.

THE patient, a male child aged one year and 6 months, was brought to me for treatment with the following history:—

About a week before the patient came under my notice, he had suffered from occasional attacks of vomiting, commencing on his rising in the morning and continuing intermittently throughout the day. High fever for a couple of days. The mother then first observed that the child was unable to move his limbs by himself, and when propped up, could not keep his head steady.

Present condition.—Use of the upper extremities entirely lost and movement of lower extremities slightly impaired, the head could not be kept steady, it was continually falling to one side or the other. Cutaneous sensibility not impaired. No tendency to inflammation of the urinary organs, no facial paralysis, no ptoxis or eruptions anywhere on the body.

Treatment.—Quinine with Liqr. Aromaticus was given in full doses four times a day, and the limbs and spine were rubbed with camphor liniment twice a day. On the third day there was a slight improvement in the movements of the legs, and Tincture Ergat (Mij) was added to the mixture. The patient now steadily improved and on the 7th day could sit up of his own accord and was able to keep his head erect. I now lost sight of the patient for about three months, and when I saw him again, the movements in the upper extremities were entirely restored, the head perfectly steady, but he was quite unable to stand, and when supported and made to walk, the left leg hung quite loose and was dragged along. The

muscles of the left leg and thigh were flabby and the hand was cold in the distal extremity. Legginess occurred.

Remarks.—The earliest onset after the previous night sleep and fever, the absence of delirium or any tendency to inflammation of the urinary organs and the want of uniformity in the paralysis of the upper and lower extremities led me to diagnose acute anterior Poliomyelitis, and this is confirmed by the condition that now exists after three months. I am, however, sorry I had not the means to test the electrical reaction of the muscles at the time of admission, during the progress and after recovery. The points worthy of remark are:—

(1) The loose condition of the hand.

(2) Rapid improvement.

(3) The parts which were most involved recovered completely (i.e. the upper extremities and the head), while the limb which was at first least affected, became paralyzed later on.

AN UNUSUAL CASE OF PENETRATING WOUND OF THE ABDOMEN.*

UNDER THE CARE OF SURGEON-CAPTAIN DUNE, I.M.S., General Hospital, Rangoon.

THE following very remarkable case demonstrates the small amount of shock which may follow the infliction of serious injury to the intestine. Death resulted obviously from the internal hemorrhage and not from the wound of the bowel, for the patient lived only twelve hours, and this was much too short a time for any extravasation of the intestinal contents to have led to this result. It is difficult to see how the severity of the case could have been recognised immediately after the infliction of the injury.

A healthy, well-nourished native of Burma, aged about thirty years, was admitted at 8.30 A.M. on 1st March 1897, to the General Hospital, Rangoon. While squatting in Eastern fashion in a corner of his house with his back to the wall someone outside the house stabbed him in the buttock through the thin bamboo matting of the wall. He did not apparently attach much importance to his wound. On examination a transverse wound one and a half inches long at the level of the lower end of the sacrum and just to the right of the midline line was found. A probe passed in about one inch and impinged upon bone. The rectum was examined and no injury was detected. The pulse was good; the patient complained of little pain and there were no symptoms of shock. At 7.30 P.M. Surgeon-Captain DUNE was called to see the patient and found him moribund. He was almost pulseless; his abdomen was distended and there were signs of much fluid within it. He died very shortly afterwards.

Necropsy.—At the post mortem examination the track of the wound was found to pass between the sacrum and the coccyx. The floor of the pelvis to the right of the rectum was perforated. A coil of small intestine about midway between the stomach and great intestine hanging in the recto-vesical pouch was penetrated. The abdomen contained a great quantity of blood, the source of which was not demonstrated, but was probably the right internal iliac vein or one of its large tributaries. The dissection was performed by one of the hospital attendants in the presence of Surgeon-Captain DUNE, but his skill was not sufficient to demonstrate this point. Having other surgical cases to attend to, Surgeon-Captain DUNE was unwilling to perform the dissection himself. All the other organs were healthy and uninjured.

Remarks by Surgeon-Captain DUNE.—The above case seems to be worthy of note as what appeared to be an injury of no great severity was in reality very serious, and that the real extent of the wound was not manifest at a time when successful operative measures might have been adopted.

THE
Indian Medical Record.

1st April 1898.

THE SERUM DIAGNOSIS OF TYPHOID FEVER
AND THE RESULTS OBTAINED
FROM IT.

THE blood or serum of patients suffering from typhoid fever, when mixed with living typhoid bacilli in solution, has the power of arresting their movements, and of collecting them into groups or clumps; this is called the agglutinative power or reaction.

It is also known in general as PFRIFER's reaction, and was demonstrated by him and others before WIDAL's name was connected with it.

In general, the serum of an animal suffering from a specific infection has the power of agglutinating, or clubbing, the specific bacillus of that infection.

This agglutinative serum-reaction appears to be of wide, although not universal application, and has been demonstrated for typhoid, cholera, tetanus, Malta fever, glanders, and other infections.

To WIDAL belongs the credit of applying this general law to differential diagnosis.

In applying the serum-reaction test a considerable number of precautions have to be taken in order to get reliable results. It will be our endeavour in the following columns to make these clear, and to give a brief account of some of the results already obtained and published.

METHOD OF TAKING MATERIAL FOR TESTING.

Either pure serum, blood, or blood serum, can be employed.

Serum may be obtained from a fly blister, and gives accurate results.

Dried blood, as recommended by WYATT JOHNSTON, has however many advantages, more especially where the specimen has to be sent to a distance.

A drop of blood is taken from the carefully cleansed finger, or the lobe of the ear, placed on a glass slide and allowed to dry, in this state it can be sent off, and preserves its properties for weeks or even months.

No special precautions are necessary for keeping it sterilised during transport.

TYPHOID CULTURE AND MEDIA.

For the test fresh typhoid cultures must be used not more than twenty-four hours old, if possible.

If care is not taken in the preparation of the cultures, a dangerous source of error crops in, in the form of pseudo-reactions; this results from the fact that some typhoid cultures have a tendency to "club" spontaneously, and others on the addition of any non-typhoid blood or serum.

WYATT JOHNSTON and McTAGGERT state that a safe cultivating medium to use is Bouillon *slightly acid* which just reacts on litmus, and requires 3.5 per cent. normal alkali to restore the tint to Phenol Phthalein. DELEPINE, recommends a neutral bouillon.

The former observers consider that the important factor is the nature of the growth, not the reaction of the bouillon, and state that they can get as good results with a bouillon of considerable alkalinity; temperature and other conditions may have some influence.

MODE OF APPLYING THE TEST.

Dilution of the Blood or Serum.—A second source of error has here to be guarded against.

It has been found that normal and non-typhoid blood and serum frequently possess distinct agglutinative properties, but they are small compared with blood and serum specifically infected, and the fallacy can be avoided by diluting the material used for the test.

The degree of dilution is of considerable importance. WIDAL suggested one of blood to nine of water, or 1 in 10; it has however been found that non-typhoid blood and serum, even when diluted to this extent, will sometimes agglutinate the bacilli, so that most observers are now in favor of a higher degree of dilution, say 1 in 40 or 1 in 50, and it is believed that non-typhoid blood or serum, when diluted to this extent, will not give the characteristic reaction.

The degree of dilution at which typhoid blood or serum will sometimes agglutinate the bacilli is enormous, 1 in 12,000 according to WIDAL. FRANKEL found the average to lie between 1 in 100 and 1 in 200.

It follows that the higher the degree of dilution with which the agglutinative serum-reaction is obtained, the more positive the diagnosis, but for all ordinary purposes a dilution of 1 in 40 is considered to be sufficiently accurate.

METHOD OF DILUTING AND MIXING.

Supposing dried blood is used and the degree of dilution required is 1 in 10, four drops of distilled water are added to the blood, and they are mixed together, to this five drops of bouillon culture are added and the result observed in a hanging drop preparation under an immersion lens. A control experiment should always be done at the same time.

WYATT JOHNSTON and McTAGGERT have adapted this method to quantitative work by taking the blood, water and bouillon with a copper loop of the same size; in this way each material is accurately measured.

The amount of bouillon added should be about equal to the amount of blood and water, or serum used.

WRIGHT has described an ingenious method by which the test can be applied without the aid of a microscope; for his method certain appliances, glass capillary and sedimentation tubes are required, which though easy of construction in a laboratory, under certain circumstances present difficulties.

They are figured and described in detail in the *British Medical Journal*, 5th February 1899; the method is very simple in application if the tubes or the means of constructing them are at hand.

TIME LIMIT FOR THE TEST.

Another important point is the time that should be allowed for the working of the test, as late agglutinations are not trustworthy.

The time differs according to the degree of dilution, for a dilution of 1 in 10—15 minutes is held to be suffi-

ant, while two hours should be allowed for a dilution of 1 in 50.

PERIOD IN THE DISEASE, AT WHICH THE REACTION IS PRESENT.

It may be considered to be one of the drawbacks to this method of diagnosis that the reaction does not, as a rule, appear before the seventh day, while it is during the first week that it would certainly be most useful, it increases in intensity as the disease progresses.

In some cases it has been noticed that it is not constant, but may be present one day and absent a few days later and then present again; for this reason every case should be tested several times.

The reaction sometimes persists a long time after recovery: In some cases for years, a fact that has to be borne in mind in making a diagnosis, for it is obvious that at the time the test is applied the patient may be suffering from some other disease; while a positive serum reaction may be due to an antecedent typhoid fever.

RESULTS OBTAINED.

"WIDAL gives the following:—

The three latest extensive series of French statistics are those of M. M. GASNER, PAUL COURMONT, and BENSAUDE. The first relates to 112 cases of typhoid fever, the second to 257, the third to 61.

In no one of these patients did the reaction fail.

I have examined personally the serum of 177 typhoid patients, and have been unable to demonstrate the agglutinative reaction only in one single case."

Mr. R. C. CABOT, of Boston, collected statistics of 1,826 patients supposed to be suffering from typhoid fever, the test confirmed the diagnosis in 1,744 cases or 95.2 per cent.

Dr. GILMAN THOMPSON publishes statistics of 503 cases, 156 of which were undoubtedly typhoid, collected from five of the larger New York hospitals, and gives the following summary of results:—

1. Cases diagnosed clinically as typhoid fever in which the test was positive, 157.

2. Cases diagnosed clinically as undoubted typhoid fever in which the test failed completely, 6. One of these was tested on the seventh day and one on the eleventh. One was tested three times, and died of intestinal perforation the day following the last negative test.

3. Ratio of failures of the test in undoubted typhoid fever, 1.26, or nearly 4 per cent.

4. Cases diagnosed clinically as probably enteric fever, in which the test failed, 11. One of these subsequently developed inguinal adenitis.

5. If the failures in probable cases be added to those of undoubted cases of typhoid fever, the total ratio of failures of the test in typhoid fever rises to 1.94, or 10.8, nearly 11 per cent.

6. Cases decisively diagnosed as other than typhoid fever in which the test was positive, 20. In a few of these cases the test, though positive, was not considered strong enough to suggest a typical typhoid reaction.

7. Ratio of these misleading cases as compared with the genuine ones, 1.8 (nearly), or approximately 12 per cent. The diagnosis of some of these 20 cases was as follows:—Carcinoma of pylorus, meningitis (variety?), nephritis and uræmic coma (reaction excellent), appendicitis with perforation (reaction excellent), chronic endocarditis (examined three times), pneumonia (examined several times, failed after eighth day), endometritis (moderate fever for ten days, which subsided after onset), suppurative subdeltoid bursitis (acute bronchitis), pleurisy with effusion (serum, 1 to 10), diarrhoea (blood, 1 to 10), acute endocarditis (blood 1 to 10, feeble reaction), malarial fever (serum, 1 to 10), malarial fever (serum, 1 to 10), malarial fever (blood 1 to 10, reaction moderate on sixth day, absent on eighth day), acute articular rheumatism, general military tuberculosis.

His conclusions are:—The WIDAL test is unquestionably ingenious, and it constitutes a most instructive and suggestive bacteriological demonstration; but is it more than this—is it of genuine practical diagnostic value to the clinician? The great majority—fully 75 or 80 per cent.—of cases of typhoid fever need no confirmatory test beyond the plain history and symptoms, and the remainder in which such a test, if accurate and exclusive, would be invaluable are chiefly: (1) Cases of enteric fever seen very early in the course of the disease, principally in private practice; (2) cases of obscure sepsis; (3) severe or protracted cases of malarial remittent fever; (4) certain cases of typhus fever and of acute military tuberculosis; (5) various atypical forms of enteric fever.

Dr. GILMAN THOMPSON is not the only observer who has reported positive agglutinative reaction in diseases other than typhoid fever.

LOUIS B. WILSON and F. F. WASHBURN got a positive reaction in influenza, acute mania, puerperal mania, and poliomyelitis with paralysis of the lower extremities, in none of which could a history of previous typhoid fever be elicited.

PATELLA reports a positive reaction in a case of ulcerative endocarditis.

In spite of these objections, almost all observers are agreed as to the wonderful power and value of this method of serum diagnosis, and its ease of application is not its least credential.

The question we have to consider is how does it affect us in India.

It is notorious that the ravages of typhoid fever amongst European troops have attracted a great deal of attention, and caused much uneasiness, it is also the case that this disease appears to be on the increase.

Now from what has come to our ears, we are led to believe that in many of these cases there is a certain element of doubt, to say nothing more, and for many reasons we are led to believe that the diagnosis of typhoid fever presents difficulties in this country which are unknown in England.

If we are right in this opinion, it is evident that the introduction of the WIDAL method of diagnosis would be of incalculable value.

Again we have heard of typho-malarial fever, and we have frequently seen it remarked about cases of typhoid

fever that they have a material point or complication, but we are not aware that both the plasmodium and the typhoid bacillus have ever been demonstrated in the same case.

If the plasmodium were found in a case that gave the Widal reaction, it would go far to place typho-malarial fever on a sound footing, and the bacillus could be demonstrated subsequently.

Another point upon which we would lay some emphasis is our present ignorance of the part that typhoid fever plays amongst the native population; here then is a wide field for fruitful research.

FENNER lately stated that he got a positive WIDAL reaction in 20 out of 15 apparently healthy natives, the assumption being that they had suffered from typhoid fever at some previous time.

We should very much like to see the WIDAL method put to the test in some of the native fevers where there is a high mortality, and where conditions of filth abound, as for instance in the now notorious fevers in the town of Madras.

REFORM IN INDIAN MEDICAL EDUCATION.

THE subject of Medical Reform—that is reform in medical education and examinations, has come prominently to the front in Great Britain.

Sir CHRISTOPHER JOHN NIXON, M.D., in his Presidential address to the Dublin branch of the British Medical Association, summed up in an admirable way the objects to be attained in the future and the means of attaining them.

"If I were permitted," he says, "to outline the direction in which reforms should be made, I would indicate them as follows: (1) A uniform standard of preliminary examination; (2) a uniform standard of professional examination; (3) a more efficient and more extended exercise of the disciplinary powers of the General Medical Council—these changes to be effected by amendments of the Medical Acts."

Such being the position which the leading medical men in the United Kingdom are gradually finding it necessary, both in their own interests and in the interests of the public to take up, it may be interesting to take a glance at the condition of medical education and examinations in the Indian Empire.

In the first place we have no body comparable to the General Medical Council to supervise education and protect the public from the dealings of unqualified persons. In India everything is in the hands of the Government of the country.

How does the Government look after the interests of the public by upholding the standard of medical education?

As a question of practical importance, it seems to have been altogether lost sight of, so varied and widely divergent are the standards with which we are surrounded, while the number of new schools constantly arising and granting their own diplomas must strike dismay into the minds of any one interested in the future welfare of the medical profession in India.

The uniform standard of professional examination, the one portal system so ardently hoped for by some English reformers, is by many considered as almost beyond the

limits of possibility, so varied and conflicting are the many vested interests in that country, but in India, where everything is so powerful and the medical institutions so few, the question presents no difficulties that cannot be easily overcome.

As things go on, and the Empire advances in civilization, the existing universities and schools will become more powerful, and may confidently be expected to come into competition with one another. Such competition is bad and tends to deterioration, it is an evil influence, as Sir CHRISTOPHER NIXON says:—"To get rid of the evil influence of competition amongst the various examining bodies is the problem to be solved."

Well, at the present day it hardly exists in India, but that it will arise in the future, if not prevented, no one can doubt.

Unfortunately in this country, at the present day, the tendency is to lower and not to elevate the standard of medical education. The Government seems to accept anything in the shape of a doctor as good enough.

This is a question which demands the earnest attention of the universities; it is obviously one of the chief functions of a university to uphold and elevate the standard of education, and if it fails to do this, its influence and importance must become depreciated.

Now what is to be said of a university, that without protesting, permits private bodies to grant counterfeits of its degrees? What can we say, except that it has become a nonentity as far as its influence over education and even over its own rights is concerned.

Yet we have several bodies granting these hybrid diplomas, there is the V. L. M. S. which stands for Vernacular Licentiate of Medicine and Surgery, L. T. M. S. Licentiate of the Temple Medical School, what are these but imitations of the L. M. S. of the universities.

These titles are astonishing enough, but what strikes us with utter amazement, is to find the exact counterpart of the university degree granted under the auspices of the Dufferin Fund. How has it come to pass that this Fund grants a license in medicine and surgery?

The whole question must be raised as to the legality of these licences, under what authority are they given and what benefits do they confer?

Are the holders of them held to be qualified practitioners in the eyes of the law?

The criterion of qualification in Great Britain is Registration, under the Medical Acts of the United Kingdom the degree or diploma in itself is not sufficient to constitute a qualified practitioner, it only enables the holder to be registered. It is registration which confers the benefits accruing to qualification.

A person who is unregistered is unqualified before the law.

What is the criterion of qualification in India? Under what authority do these different schools, and even private bodies, grant licences to practice medicine and surgery, and who is responsible that the education given by all these bodies is up to the necessary standard? All these are matters which require elucidation, and it is to the interest of all concerned that they should be put on a proper footing.

the fact which they lived in collecting specimens, and the produce suddenly snatched from them and put forth for the profit of others, with the additional mortification of finding what they had taken so much pains with, disgraced with bad English and ridiculous and mischievous blunders."

The *Lancet* was not behind hand. "The outward resemblance of the new paper to the *Lancet* was great, while all the Editorial inspiration had been borrowed from WAKLEY."

"Some despicable imitations of us have arisen," said WAKLEY, and *stunk*, and became extinguished "one or two are still smutting a little faster."

WAKLEY's attack upon the Royal College of Surgeons forms not only an important episode in his own career, but a memorable event in the history of the medical profession; by it his influence was tremendously increased, and he came to be looked upon as the champion of the rights of the general practitioners of England.

He first fell foul of the College on account of a bye-law passed in March 1824, making it compulsory for students to attend the lectures of certain hospital officials, including the Professors of Anatomy and Surgery in the Universities of Dublin, Edinburgh, Glasgow and Aberdeen. This increased the power, the authority, and the emoluments of the metropolitan surgeons and lecturers, and gave them a complete monopoly in the surgical education of the London students.

This bye-law would evidently bear very hard upon private schools like the Webb Street School conducted by the Graingers, exceedingly able anatomists, who had a reputation as instructors that entirely put in the shade that of the four members of the combined staff of the Borough Hospitals.

WAKLEY was largely educated at this school, so that we may assume that his sympathies were with it; moreover, these same hospital surgeons, in whose interest the bye-law was formulated, were the very men whom WAKLEY was showing up for insufficiency and corrupt practices.

The official ring was thus arranged. The hospital surgeons appointed the lecturers to the medical schools—that is, they appointed themselves, their relations, and the gentlemen who had paid them large fees to become their apprentices.

In this contest WAKLEY received much assistance from JAMES WARDROP, one of the greatest surgeons of the day, who contributed a number of letters over the signature of "Brutus," calling attention to the various grievances the profession suffered at the hands of the college authorities.

The publication of these letters caused great excitement in the profession, and called forth many similar expressions of resentment from the practitioners throughout England, which showed that the dissatisfaction of the commonsense of the college with their rulers was very real and very widespread.

Seeing that he was so strongly supported, WAKLEY pledged himself to a definite course, namely, the procuring of measures of redress.

His first step was to propose that a general meeting of

the profession should be held for the purpose of a campaign.

This meeting was held at the Royal College of Surgeons, and was the first public meeting of the kind since the College of Surgeons of England.

Through WAKLEY's influence the House of Commons and Parliament for redress, and a committee of inquiry was appointed to prepare the petition. The Council of the College was asked to join in the petition; but very naturally refused.

ABERNETHY was at that time the member of the Council, and he presented to the members of the College the Council's refutation of the charges brought against it; the refutation however refuted nothing, but only added fresh insults to those which had already been accepted by the members for years.

One point of interest came out—that a large quantity of HUNTER's *Mss.* had been burnt by Sir EVANAR HOME. These consisted of ten folio volumes. Nine on the anatomy of animals and one on vegetables; the reason given for this act of Vandalism was a promise made to HUNTER.

The petition took a year to prepare, and so luke-warm did everyone concerned become that it would never have been prepared at all had not WAKLEY with indomitable perseverance pressed it on. ROBERT PEELE having declined, it was presented to the "House" by Mr. WARBURTON, on 20th June 1827.

The result was that the College was called upon to render an account of its stewardship, thus the members gained a victory, but it was a barren one; the document called for was laid on the table, no debate ensued, and nothing more was heard of it. This was a great disappointment to the reformers, but WAKLEY stuck to his self imposed task and continued to "peg-away."

—o:—

THE FOURTEENTH MEETING OF THE COUNCIL OF THE INDIAN MEDICAL ASSOCIATION.

IN accordance with notices issued by command of the President, the 14th meeting of the Council of the Indian Medical Association was held at its Office, 150 Dharamtala Street, Calcutta, on Thursday, the 17th March 1898, at 6 P.M.

Present.—DR. LAL MADHAB MOOKERJEE, Rai Bahadur, (President in the Chair), DR. E. W. CHAMBERS, Vice-President; Drs. H. W. JONES, K. G. SIKKAR, H. C. HODGKINS, JAMES FORSYTH and J. R. WALLACE.

Business.—(1). The notice calling the meeting having been read, the minutes of the last regular meeting of the Council were read and confirmed.

(2). The Secretary represented that in compliance with the instructions of the Government of India and the Government of Bengal, the Council was called upon to forward to the Military Department of the Government of India and the Chief Secretary to the Government of Bengal, a statement of the grievances of the local military services, in view to their early consideration by the Government. The following letters were approved of and

TO THE SECRETARY to the GOVERNMENT of INDIA,
Military Department.

Sir,—In compliance with the instructions of the Government of Bengal in its Letter No. 276, dated 18th January 1898, the Council of the Indian Medical Association begs respectfully to place before the Government of India the following suggestions for the amelioration of the grievances of Military Assistant Surgeons in regard to status, pay and allowances.

1. The abolition of the term "subordinate" from the designation of their department, which may be styled the Indian Medical Department.

2. The abolition of the lowest grade of Assistant Surgeon, so that Military Medical Cadets, on passing the qualifying examination from the Presidency Medical Colleges, shall receive the rank of second class Assistant Surgeon with a salary of Rs. 100.

3. That in view of this improvement in the department all candidates shall in future be expected to have passed the Matriculation or Entrance Examination of an Indian University or the High School Examination of the Government European Code, and further that the period of education in College be extended from four to five years.

4. That promotion in the Department be regulated by a tenure of five years' service in each grade.

5. That an enhanced pension of Rs. 250 be granted to Commissioned Assistant Surgeons.

6. That the term Senior Assistant Surgeon, as applied to Honorary Commissioned Officers, be abolished.

7. That the rate of travelling allowance be allowed to the various grades at a fixed rate of Rs. 2 per diem.

8. That Military Assistant Surgeons holding the appointment of Civil Surgeon be graded in the First Class travelling allowance list.

Earnestly soliciting that the Government of India will be graciously pleased to accord an early and favorable consideration to these suggestions.

I have the honor to be,

Sir,

Your most Obedient Servant,

JAMES B. WALLACE, M.D., F.R.C.S.,

Secretary, Indian Medical Association

TO THE SECRETARY to the GOVERNMENT OF INDIA,
Military Department.

Sir,—In compliance with the instructions of the Government of Bengal in its Letter No. 276, dated 18th January 1898, the Council of the Indian Medical Association begs respectfully to place before the Government of India, the following suggestions for the amelioration of the grievances of Military Hospital Assistants in regard to status, pay and allowances.

1. That they receive definite military rank as Subedar, their present status being very ill-defined.

2. That they receive the designation of Sub-Assistant Surgeon and the senior grades the title of Honorary Assistant Surgeon and honorary commissions as Subedar-Major.

3. That the graded salaries be increased as follows.—

Senior Hospital Assistant	...	Rs. 120
1st Class " "	...	90
2nd " "	...	60
3rd " "	...	40

4. That improvement be made in the matter of medical charge allowance, foreign and native service allowance, travelling allowance, uniform allowance (or free uniform) and pension, as under each of these heads considerable hardship is experienced.

Earnestly soliciting that the Government of India will be

YOUR MOST OBEIENT SERVANT,

JAMES B. WALLACE, M.D., F.R.C.S.,

Secretary, Indian Medical Association.

(Similar letters have also been sent to the Government of Bengal.)

(5). The Secretary read the following letter having reference to the prohibition of private medical practice to the Civil Surgeon of Mussoorie:—

NO. 109
HUB. ON 1898.

From the UNDER-SECRETARY to GOVERNMENT.

N. W. Provinces and Oudh

To the SECRETARY,

Indian Medical Association, Calcutta.

Dated Allahabad, 28th February 1898.

Sir,—I am directed to acknowledge the receipt of your Medical letter, dated the 18th December 1897, in which, Department on behalf of the Council of the Indian Medical Association, you ask His Honor the Lieutenant-Governor and Chief Commissioner to prohibit the Civil Surgeon of Mussoorie from engaging in private medical practice, on the ground that this is prejudicial to the public interests and to the interests of the private medical practitioners resident in the station.

2. In reply I am to say that the Lieutenant-Governor has given due consideration to the representation made by the Association, but finds himself unable to grant the Association's request.

I have the honor to be,

Sir,

Your most obedient servant,

H. R. C. HALEY,

Under-Secretary to Government,

For Secretary to Govt. N. W. Provinces and Oudh.

After discussion on the above letter, it was resolved that before this matter be forwarded to the Secretary of State for India, the Secretary submit correspondence in connection with this matter to the Government of India for favorable consideration of the Council's representation to the N. W. P. and Oudh Government.

(4). The Secretary read letters from the Governments of Bombay, Central Provinces, Assam and from the Director-General, Indian Medical Service, concerning the recent representations of the Council in regard to the grievances of the Local Medical Services.

(5). The Secretary presented the applications of 32 new members for the Association, received since last meeting. They were all duly elected.

(6). The Secretary read a letter received from the Bengal Government relative to the Plague Commission.

(7). The Secretary read an important letter from certain Civil Assistant Surgeons complaining of a new grievance that had been inflicted upon them by the recent orders of the N. W. P. and Oudh Government, the practical effect of which is to deprive Civil Assistant Surgeons of their status as gazetted officers.

Resolved that application be instantly made to Government for a copy of the orders referred to, and that the serious consideration of the Council be given to the subject at the earliest possible date.

(8). The Secretary read a letter from Mr. J. F. FERNANDES, Medical Officer, Rajputana-Malwa Railway, soliciting the Council's support with reference to the much discussed question of a recognised State medical diploma of lower value than a university degree.

Resolved that the whole subject be considered at the next meeting of the Council.

With a vote of thanks to the chair the meeting was closed.

the patient is placed in the supine position, and the limb is raised up to the level of the heart. The limb is then placed in a position of flexion, the knee joint being bent at a right angle, and the foot resting on the thigh. The patient is then placed in the supine position, and the limb is raised up to the level of the heart. The limb is then placed in a position of flexion, the knee joint being bent at a right angle, and the foot resting on the thigh. The patient is then placed in the supine position, and the limb is raised up to the level of the heart. The limb is then placed in a position of flexion, the knee joint being bent at a right angle, and the foot resting on the thigh.

PUT IT IN WRITING

Two cases which bring home forcibly to medical men, especially those holding public positions, the importance of attention to details, and the value of having everything in writing, have lately attracted some attention in the English medical journals.

The first is known as the "Dereath Asylum Case." In this case it appears that a female patient became pregnant and in the course of time died in her confinement, 30th November, 1887.

As the result of the inquiry, Dr. WATSON, the medical superintendent, was called upon by the managers to resign immediately.

The case against Dr. WHITE is as follows:—

- (1). That having had no obstetrical experience since his student days, he was unwise to undertake the case.
- (2). That although Dr. WHITE became aware of the pregnancy on 22nd July there was no entry in the case book till after death. There was a total absence of records.
- (3). He made no writing report of the pregnancy to the Committee.
- (4). No qualified nurse was obtained or recommended in writing by Dr. WHITE.
- (5). No communication was made to the coroner.
- (6). There was no post-mortem.

Of these six allegations, Nos. 2, 3 and 4 appear to be the important ones. But against the first that Dr. WARRIN failed to communicate with the Committee in writing, it is shown that the Committee were aware of the facts; for in their report of 14th December 1907, they state that the Clerk to the Board and the Chairman of the Committee made minute inquiries into the facts, and a special meeting of the Committee thereon was held on 13th August 1907.

This fact would seem to exonerate Dr. WHITE. He had mentioned the matter privately to the Chairman of the Committee and the Committee had taken cognizance of it; and from that time the responsibility would appear to have passed from Dr. WHITE to them; and no doubt but J. W. WHITE made some official report that would have been the case.

The General Purpose Committee, who inquired into the matter, reported:-

• We consider that in failing to apprehend the gravity of the situation and in neglecting to make proper arrangements for the care of our young experimental animals and human subjects, and in omitting to report to this Board (The Air Force Board) the full contents of the letter of the

Representative of the House of Representatives expressed that there was some feeling of apprehension and on the matter of the suspension of the House, the Senate Committee have failed to discharge, as they ought, the duties assigned to them."

As we have seen, however, the movement preferred to make a scapegoat of the medical establishment, in fixing a proper share of blame on the Darwinian Revolution.

Dr. Warren has declined to resign, so far as we have no seen the last of this case, which seems to be over. For practical protection.

The other case was one where the Medical Officer of Health for Honolulu seized a portion of a carcass of a cow to sell for human food. In this case the owner of the carcass gave his consent, but the medical officer did not insist on having it in writing.

The result was that the owner changed his mind and having got sufficient evidence in favor of the meat, brought an action against the Rochdale Corporation and got a verdict for \$50 damages.

Some new legal points then cropped up. The Corporation pleaded that they were not responsible for their medical officer's action, as they were obliged by statute to appoint such medical officer. Mr. Justice Bowen, however, decided against them and held them responsible because the medical officer had acted on regulations laid down by themselves, but had not adopted the statutory method of notifying the destruction of the carcasses in a magisterial decision, that is, he had not observed the details of procedure laid down by law, which details we believe are very thoroughly perfected.

The above decision against the Corporation appears to have been given, partly because that body retained the power to remove their health officer in a three months' notice and to determine his salary, and also that he had been appointed by the Corporation to carry out regulations they themselves had laid down. On such nice points do these decisions hinge.

On the other hand, if the Local Government Board had paid part of the health officer's salary, and if his appointment and dismissal had been in their hands, it is very probable that the health officer would have had to meet the responsibility himself.

This aspect of affairs may turn out to be a very serious one for medical officers of health.

As the Corporation have appealed against Mr. Justice BRUNN's decision, the matter is not yet at an end.

OLD RECORDS ABOUT PLAGUE IN INDIA.

Says the *British Medical Journal*.—"In the January number of the *Indian Magazine* Mr. ALEXANDER ROBERTS points out that the epidemic of plague now raging in the Bombay Presidency bears a striking resemblance to one which occurred about 250 years ago at Agre and in the North-West. In illustration of this he quotes the following passages from the Emperor Jehangir's autobiography referring to the thirteenth year of that monarch's reign, *circa* A. H. 1038):

"The daughter of the deceased ASAF KHAN, who is in the house of ABDUL KAH KHAN, son of the KHANSA KHAN, told me a strange and wonderful tale. I made particular inquiries into its truth, and write it on account of its strange-ness. She said that one day in the courtyard of her house she saw a mouse falling and rising in a convulsed state. It was shaking about in every direction, after the manner of drunkenness, and did not know where it was. She said it was one of her female slaves." "Take it up by the tail and throw it before the cat." The cat, therefore, jumped up from its place, and seized it in its mouth, but immediately dropped it and showed aversion to it. By degrees an expression of grief

and pain showed itself in its stage. The next day it was nearly dead, when it entered into its final stage. The mouth was opened its gaites and tongue appeared black. It passed three days in a state of misery, and on the fourth day came to its end. After this the grains of the plague (buboni or bubo) appeared in one of the female slaves, and from excess of temperature and increase of pain she had no rest. Her color became changed; it was yellowish, inclining to black, and the fever was high. The next day she was free of fever and died. Seven or eight people in the house died in the same way, and some were ill. On that day I went to the garden from that halting place those who were ill in the garden died, and in that place the bubo did not appear again. Briefly, in the space of eight or nine days seventeen people became travellers on the road to annihilation. She also said: 'Those on whom the pest appeared, if they asked another person for water to drink or bathe in, these also caught the infection, and at last it came to such a pass that through excessive suspicion no one would pass near them.'

A previous passage runs as follows:—At this time those who were loyal represented that the disease of the plague (Taun) was prevalent in the city of Agra, so that in a day 100 people, more or less, were dying of it. Under the armpits, or in the groin, or below the throat a lump comes, and they die. This is the third year that it has raged in the cold weather, and disappeared in the commencement of the hot season. It is a strange thing that in these three years the infection has spread to all the towns and villages in the neighbourhood of Agra, and there has been no trace of it in Fattahpur (Sikhr), and as far as for two and a half hours from Amanabad to Fattahpur. The people of that place have forsaken their own homes and gone to other villages."

RULES TO BE OBSERVED PRIOR TO THE PERFORMANCE OF MAJOR OPERATIONS.

SURGEON-MAJOR A. LEAHY, M.D., F.R.C.S. Eng., Surgeon-Superintendent, South Suburban Hospital, Calcutta, has the following rules in force in his hospital:—

A. The Preparation of the Patient.

1. Oil is to be administered overnight.
2. In all rectal, urethral and abdominal cases, an enema is to be given.
3. Emptiness of the bladder is to be secured.
4. The skin over the site of the operation should be thoroughly washed with soap and water and afterwards covered with a piece of dressing soaked in perchloride of mercury solution for 6 hours—strength 1 in 500.
5. In abdominal, rectal and urinary cases, all hair should be shaved off.
4. In ophthalmic operations, the rules already laid down should be observed.

B. The Operation Room.

1. All instruments should be placed in a tray and covered with carbolic acid lotion—strength 1 in 20.
2. A bowl containing perchloride of mercury lotion 1 in 500 should be kept ready for submersion of the hands.
3. All dressings should be kept in a separate tray.
4. A towel soaked in a 1 in 50 solution of carbolic acid should always be placed on the table for laying the instruments on.
5. The douche can should be filled with a solution of perchloride of mercury—strength 1 in 500.
4. After each day's operations, the operation room is to be flushed, allowed to dry, and then kept closed.

C. The Instruments.

1. The Resident Assistant Surgeon will select all instruments likely to be required at any operation.
2. After use, all instruments are to be boiled.
3. No instruments, scissors, knives, needles, &c., are ever to be used by the dresser for setting dressings or bandages, or for sewing them.

D. Miscellaneous.

1. A proper supply of chloroform is always to be at hand during an operation and the wool in the inhaler is to be changed after each administration.
2. A bottle of rum or brandy should be kept in the operation room.
3. A small bottle (½ oz.) of ether, with a hypodermic syringe is also to be kept ready.
4. Sponges are not to be used for operations other than of the abdominal variety.
5. All sponges after use are to be subjected to the details of cleansing, such as are in force in the Eden Hospital.
6. During an operation, the stretcher for the removal of the patient is to be kept outside the operation room in the verandah.
7. The preparation of all ligatures, drainage-tubes, dressings, bandages, tourniquets, canteries and splints is to be in the hands of the Resident Assistant Surgeon.

THE TREATMENT OF INOPERABLE SARCOMA BY MEANS OF COLEY'S FLUID.

A PAPER on this subject by Dr. C. MANSELL MOULLIN appears in the *Lancet*.

COLEY'S fluid is a mixture of the products of the growth of the streptococcus of erysipelas and the bacillus prodigious sterilised by heat, and the rationale of the treatment depends on the long known fact, that not only malignant growths, but chronic ulcers of the skin, lupus nodules, syphilitic sores and other affections occasionally disappear rapidly after an attack of erysipelas.

Several observers have obtained good results by this method. In America opinion is divided, a committee of those surgeons appointed by the New York Surgical Society, pronounced as follows:—(1) That the danger to the patient from this treatment is great; (2) moreover, that the alleged successes are so few and so doubtful in character that the most that can be fairly alleged for the treatment by toxins is that it may offer a very slight chance of amelioration; (3) that valuable time has often been lost in operable cases by postponing operation for the sake of giving the method of treatment a trial; and finally and most important, (4) that if the method is to be resorted to at all, it should be confined to the absolutely inoperable cases.

On this Dr. MOULLIN remarks "No one, so far as I am aware, has ever advocated or practised this method of treatment for cases which were suitable for operation. And with regard to this finding I would only remark that Dr. COLEY'S cases (to take his alone) have been thoroughly verified and authenticated, and that they are neither few nor doubtful. It is no small achievement to have saved the lives of nine patients who had been given up as hopeless and dying by every other surgeon who had seen them; and one single positive result is worth any amount of negations. With such conflicting evidence it is not an easy matter to form a definite opinion.

The following are some of Dr. MOULLIN'S conclusions:—

The disappearance of sarcoma is not due to inflammation, but to an intensely rapid form of fatty degeneration comparable only to that which affects the hepatic cells in acute

yellow serosity of the liver. Induration and sloughing, when they do occur, are apt complications.

Degeneration and absorption may occur, whether the toxins are injected directly into the tumour or into some distant part of the body. In the former case, however, the effect is more rapid and the constitutional symptoms more acute.

The method is attended by a considerable degree of danger. It should therefore only be adopted in those cases for which there is no other remedy. The chief risk appears to be from collapse and pyæmia.

The toxins are of no use unless the cultures are taken from a virulent case of erysipelas or are made virulent by passing the streptococcus through rabbits.

The bacillus prodigiosus, in spite of theoretical objections, has the effect of immensely increasing the reaction.

The effect is most striking in the case of rapidly growing sarcomata.

THE GOVERNMENT CHEMICAL EXAMINER SHOULD NOT EDIT A MEDICAL JOURNAL.

In our last number we expressed our views strongly against the present Chemical Examiner to the Government of Bengal occupying, as he does, the position of paid Editor to a private medical paper, owned by a publishing firm in Calcutta. We explained that it was not in the fitness of things that an official who was constantly called upon to express his opinion in medico-legal matters in our courts of law, and was thus often brought into opposition in this way with other medical witnesses and experts, should under no consideration find himself compromised by his professional relations with his brethren or with the public, as the exponent or advocate of conflicting views and opinions such as the editor of a medical journal is constantly called upon to express. We reiterate that the position occupied by the Chemical Examiner to the Government of Bengal, as paid Editor of a private medical journal is as injudicious as it is illegal. Injudicious because of the prejudicial reasons we have already expressed, and illegal also for the same, and further because a servant of Government cannot engage his services to a private firm under a definite contract such as the Editorship of the *Indian Medical Gazette* implies. That we are right in continuing to protest against this curious anomaly we have strong official and legal opinion to prove, and we earnestly hope the Inspector General of Civil Hospitals, Bengal, and the Principal of the Calcutta Medical College will take steps to abolish this official scandal, ere public action is taken to demand it. In connection with this matter we recall the action of Her Majesty's Coroner of Calcutta, who as an Associate Editor of the *Indian Medical Record* some years ago, severed his association with this journal on the very plea for which we raise objection to the Chemical Examiner's employment on the staff of the *Indian Medical Gazette*. The following letter explains itself :—

To JAS. B. WALLACE, M.D.,

Editor and Proprietor of the *Indian Medical Record*.

Wolsted House, 20 Kyd Street, Calcutta, 22nd March 1898.

SIR,—With reference to the understanding only very recently come to, that I should take up the position of an Associate Editor of your medical journal, I now find that official life, and my interest in medical journalism, are incompatible.

I am reluctantly compelled therefore to request that you will kindly remove my name from your journal as an Editor.

Wishing the *Indian Medical Record* the success it so worthily deserves.

Yours etc., E. W. GRAMBS.

It is logical to assume that what a medical gentleman of Dr. GRAMBS' age and experience felt to be his conscientious duty, will strike most straightforward honest-minded people, as being a very good estimate of what is correct and right.

UNION OF THE MEDICAL PROFESSION.

AN eminent surgeon in London, years ago complained that his *confères* were like "thunder," "whose hand was against every man, and every man's hand was against him."

The "battle of the clubs," a constant bickering in the *British Medical Journal*, shows what a suicidal policy the profession has adopted, and how inferior competition without any restriction is.

As two notorious illustrations of the lack of esprit de corps amongst medical men we may cite the following :—

Dr. BARTOUL was elected a direct representative of the profession in the General Medical Council, but very soon resigned his seat, publishing his reasons for so doing, namely, that he received no support from his *confères* in his efforts at reform, and he could not afford to go on expending so much time and money for them without result. Similarly, at the annual meeting of the British Medical Association in London in August 1896, Sir B. W. FOSTER, in a speech at a general meeting in Exeter Hall, upbraided the profession for neglecting to support him, saying that he had been three years a member of the late Liberal Government, but in all that time not a single medical man afforded him the slightest help in his efforts at sanitary reform. We can add our personal testimony. Some years ago, the College of Physicians of London published some regulations, to which some of the licentiates objected, and one of them proposed to establish a committee to protect their privileges. By a curious coincidence this complaint appeared almost simultaneously in this journal and the home papers, so we sent a marked copy to the gentleman who proposed to form the committee, promising to subscribe to his committee when started. In course of time he wrote to thank us for the paper, and to say that he regretted he could not accept our subscription, for except ourselves, no one else in the profession had taken the slightest notice of his suggestion. If the profession will not combine, it need not expect that either Government or the public will take any notice of its complaints. Readers of this journal may remember how the Madras Government persecuted Dr. KING some years ago, because he published his method of preserving vaccine in lanoline, without having obtained permission to do so from Government. The facts were sent by Dr. KING to this journal, which published them, and the *British Medical Journal* supported it in crying shame on the ignorant and tyrannical Government, so that Dr. KING was re-instated in his appointment. This success ought to encourage the members of the profession to support each other on all occasions, just as the lawyers and clergy support each other.

THE BRITISH MEDICAL JOURNAL ON THE ANGLO-INDIAN QUESTION.

THE *British Medical Journal* of 5th March 1898 says :—"This term denotes a large and various population in India. It embraces persons of pure British blood, the descendants of white parents, who for sundry reasons made India their permanent domicile, and a much larger number of persons of mixed parentage whose interests and hopes are bound up with India. This population numbers about a million, and is scattered throughout the Indian Empire, concentrated principally in the larger towns. It is a thoroughly loyal English-speaking population, and retains in great measure the physique and the habits of mind and disposition inherited from the race from which it has descended, tempered largely, perhaps to some extent deteriorated, by hybridity, climatic influences, and social degeneracies. Some of its members have attained success and position in commerce and official employ, and most of them have done useful work in Government and mercantile offices, and in occupa-

views and inclination to great industry, power, and energy, and not a few in times of emergency have exhibited remarkable heroism: a military capacity. These people represent an element in the Indian body politic which is bound to be counted and reckoned. They are eager for education, for social elevation, and anxious to take a large share in civil and military employment. Last year Dr. FANTER-BURNER, WALSLEY, a successful medical practitioner of Calcutta, while on a visit to this country, spent much of his time in urging on persons of influence the advantages of fostering and promoting this laudable ambition for better education and position. To this end he urged the formation of an Imperial Anglo-Indian Association in London, and the starting of an Anglo-Indian Patriotic Fund to defray necessary expenses connected therewith. On his return to India such hearty meetings of welcome were held in Bombay and Calcutta at which his efforts were generally acknowledged and responded unanimously accepted. The attitude of energy and self-help which these proceedings display is much to be commended; and we wish the Anglo-Indian all success in his competition with the European on the one hand and the native of India on the other.

PLAGUE REGULATIONS.

CONSIDERABLE modifications have been made in the Government plague measures in Bombay which are embodied in the following letter :-

No. 1894 of 1898. GENERAL DEPARTMENT.—Plague
Bombay Castle, 17th March, 1898

From the Hon'ble Mr. A. WINGATE, CIE, ICS., Secretary to Government, to the Chairman, Bombay Plague Committee.

Sir,—Pending the revised system of operations, which the Bombay Plague Committee will be asked to adopt on the lines generally indicated by His Excellency the Governor to the meeting of the Justices on the 15th instant, the Chairman is requested to issue stringent instructions to all the divisional and sub-divisional officers that there is to be no compulsory search in any house unless the fact is reasonably established that it is a plague-infected house.

1. No patient is to be removed to a plague hospital unless the case is undoubtedly a plague case and no medical certificate shall be accepted as evidence that the case is one of plague unless it is signed by a fully qualified medical officer.

2. That no plague case which a fully qualified medical officer may pronounce to be hopeless shall be removed to hospital without the consent of the relatives.

3. That no inmates of a house are to be removed without intimation being given to the head of the family.

4. That when any damage is caused by destruction of property (the diminution of risk of infection) compensation must in the case of the poor be paid on the spot, and there should be no destruction of property when disinfection will suffice.

The system of compulsory house-to-house visitation is to be done away with, and the notification of disease is to be placed in the hands of native committees.

These changes have been made without any reference to the Plague Committee, and some curiosity is expressed as to what its future sphere of work will be.

DR. POORE ON BUBONIC FEVER.

It is always a pleasure to come across a man who has the courage to speak himself free from the dominant opinion of the day, and with an open mind and unbiassed judgment sticks not a pin for himself. From such a one there is always much to be learnt, and such a man we find in Dr. G. V. POORE,

and whose views on the bubonic plague are of great value.

Dr. Poore writes in his paper on "Bubonic Plague," "The bubonic plague is a disease of the blood, and is not a disease of the lungs, as is often supposed."

We can only give one or two quotations from his address on the "Prevention of Bubonic Plague," before the Royal Medical and Chirurgical Society.

"Public water supplies," he says, "cannot be regarded as causes of the epidemicity of enteric fever. They without the poison with a completeness which was absolute, and insured that it was 'laid on,' as it were, in one way only." Water supplies should be arranged with means independent sub-divisions as might be possible, and supplies from different sources should never be mingled.

"The great cause of the late and wide epidemicity of enteric fever in recent years had been the water closet."

"Enteric excreta should never be mixed with water, because it was pre-eminently a water-borne disease."

"When enteric fever became suddenly epidemic, it was most often through contamination of the drinking water."

"Enteric stools in country places might quite safely be applied to the surface of well-tilled soil, they must not be mixed with antiseptics, and must not be buried deeply."

"Fæces could not be washed out of well-tilled houses by any amount of rain—in such a position faeces disappeared in a few weeks."

TUBERCULOUS MILK.

MR. SHERIDAN DELAPINE, M.B., B.Sc., in the *Lancet* says on the subject of tuberculosis, this not being a notifiable disease, there is no question of case diagnosis, our work is chiefly directed to the detection of tuberculous milk.

The microscopical method is of very little use for the detection of tuberculous milk, it is only when tubercle bacilli are very abundant that they can be discovered without considerable loss of time.

There can be no doubt therefore as to the superiority of the inoculation method when exact results are wanted, it is well known that when a guinea-pig is inoculated with even a few bacilli it invariably becomes tuberculous.

The microscopical examination, however, is not without use, for in all the cases which were proved to be tuberculous by inoculation the milk was found to contain a large number of leucocytes and epithelial cells; this presence of cells was also recognized in milk coming from udders affected with non-tuberculous mastitis and therefore is not diagnostic of tuberculosis, but tuberculosis was never communicated in my experiments by milk poor in cells. This is a confirmation of the well-known fact that the milk of tuberculous cows does not, as a rule, become infectious when the udder is not tuberculous.

The testing of milk by inoculation is not only useful with regard to tuberculosis, for in a large proportion of cases milk which has been badly kept acquires virulent properties in various degrees.

This virulence is due to other micro-organisms, which multiply rapidly, especially in summer, and which Mr. DELAPINE has good reason to believe are an important cause of summer diarrhoea.

It is therefore most important in conducting any investigation on tuberculosis to inoculate as soon as possible after milking in order to prevent the virulence and infection from that source. Or else the milk must be kept in ice from the time of collection to that of examination.

THE SEQUEL TO THE DELHI PRISONING CASE. A HARDSHIP ON CIVIL ASSISTANT SURGEONS.

IN relation to the unfortunate death of Mr. MACLEAN through the mistake of a compounder, the Civil Medical Department of the Punjab Government has just issued a circular ordering that in future all prescriptions containing poisons are to be compounded by the Assistant Surgeon or Hospital Assistant, and not by the compounder.

Anything more marked for imbecility and utter impracticability than this order cannot well be imagined.

If compounders are unfit for their duties, it would be better to do away with the whole class at once, but it is the height of absurdity to keep them on, and yet throw the onus of their work upon other shoulders which this circular amounts to.

But why are they unfit to be trusted with the compounding of prescriptions containing poisons? The admission that they are unfit amounts to a grave slur equal to a scandal on the authorities who in the first place appointed them.

If there was ever the necessity for a compounder, the necessity still exists, and cannot be glossed over by adding the responsibility for his work to the many responsibilities which the Assistant Surgeon already has to bear.

The most disgraceful part of the whole affair is that the Government ever permitted men, so unsuited by education and training to occupy such posts as compounders; and herein lies the kernel of the matter. The Government to hide its own shortcomings tries to shift the responsibility to others. But the only course open is perfectly obvious, and in the interests of public safety and efficiency it must be forced upon the attention of Government. That course is the formation of a thoroughly trained and competent class of compounders.

WHO IS RESPONSIBLE FOR THE CHOICE OF THE ADMINISTRATION OF AN ANÆSTHETIC.

A DISCUSSION on this subject has occupied the columns of a lay paper at home.

A hospital surgeon of long standing and wide experience contends that it lies solely within the province of the surgeon in charge of the case, upon the ground that he, and he only, has the opportunity of studying the case, and so is the best qualified to sit in judgment upon the points at issue.

On the other hand, a gentleman in private practice writes that at least as regards private practice, he considers the surgeon as the least competent, since the family doctor, he alleges, knows all about the patient, while the surgeon views him wholly from the stand point of his surgical malady.

In cases where special anaesthetists are called in, the problem is more complex. If competent medical men who devote themselves to the study of what is admittedly a large subject and one not free from special difficulty, and are found willing to practice solely in the capacity of anaesthetist, it becomes a grave question whether or not they should be regarded as mere experts in the methods of giving an anaesthetic and accepting no responsibility beyond that involved in the technique of their calling; or whether, on the other hand, they have a right to determine what anaesthetic is best in any given case. It is urged on behalf of the anaesthetists, that when an expert is called in to give the anaesthetic, with him should rest the onus of selecting an appropriate anaesthetic. In all cases of special doubt or difficulty a consultation between the administrator and the operator should enable the former to examine the patient, and ascertain the surgeon's views and wishes.

OFFICIAL INTEREST: MEDICAL AND NON-MEDICAL.

THE following theme may be familiar in its style to some of our readers:—

Though I speak with the languages of Hindustan and the Punjab, and have not interest, I am become as he that hath not passed the Lower Standard.

Though I have the gift of writing, and understand all Government Orders, and though I have all tact, so that I could remove mountains, and I have not interest, I am nothing.

Though I bestow all my energies upon my duties, though I have given my body to be shot at, if I have not interest, it profiteth me nothing.

Interest helpeth ever, and is kind; interest scrupleth not; interest hideth not itself, is not easily abashed, rejoiceth not in merit, but rejoiceth in family connections.

Interest never falleth; but whether there be War services, they shall fail; whether there be special qualifications they shall cease to be considered; whether there be knowledge of the languages, it shall be of no avail.

For we officiate for some, and do duty for others, but when he that hath interest is come, then he that doeth duty shall be superseded!

When I entered the service, I spoke as a griff, I understood as a griff, I thought as a griff; but when I came to know the power of interest, I put away griffish ideas.

And now there abide Special Qualifications, War Services, and interest; these three, but the greatest of these is interest.

THE VICEROY AND HIS DOCTOR.

TWO interesting announcements were made by the Viceroy in his speech at the annual meeting of the Lady Dufferin Fund yesterday. The first was in connection with his retirement, and was to the effect that he had represented to the Secretary of State the desirability, in the public interest, that whoever was selected to succeed him should take over charge at the commencement of the Calcutta season and not, as in his own case, at the end of January. Lord EGIN added that he expected, therefore, to make over office early next December, and would probably be unable to take part in another annual meeting of the Dufferin Fund. The other announcement related to Brigade-Surgeon Lieutenant-Colonel FRANKLIN, to whom Lord EGIN paid a warm tribute on account of his services to the Dufferin Fund, and added that, on the recommendation of the Government of India, the Queen had appointed Dr. FRANKLIN Honorary Surgeon to herself. News of the appointment arrived yesterday in a telegram from the Queen-Empress, and, as Lord EGIN happily remarked, was one more proof of the interest taken by Her Majesty in the promotion of medical aid to the women of India.

PLAGUE IN BOMBAY

THE number of deaths from plague in Bombay for the week ending 8th March was 1,283; for the week ending 15th March 1,059; and for the week ending 18th March 1,247.

The Mofussil Statistics are as follows.—Poona, 4 cases and 10 deaths. In the districts—Kaira, 2 cases and 2 deaths; Surat, 126 cases and 97 deaths; Thana, 29 cases and 21 deaths; Ahmednuggur 8 cases and 6 deaths; Khandesh, 29 cases and 25 deaths; Nasik, 55 cases and 52 deaths; Poona, 28 cases and 28 deaths; Satara, 111 cases and 97 deaths; Sholapore, 20 cases and 23 deaths; Kolaba, 66 cases and 50 deaths; Ratnagiri, 29 cases and 16 deaths; Belgaum, 108 cases and 81 deaths; Dharwar, 5 cases and 3 deaths. Bhiapore one case and one death. In Native

Fortification.—Baroda, 306 cases and 448 deaths; Bombay, 41 cases and 58 deaths; Kolhapur, 69 cases and 75 deaths; Ootah, 18 cases and 11 deaths; Rann Kantha, one case and one death; Palanpore, 35 cases and 23 deaths; Saurashtra, 42 cases and 6 deaths; Jangira, one case and one death; Ahambet, 5 cases and 5 deaths; Anand, 17 cases and 13 deaths. Dr. Lister's serum has not fulfilled its promise; 14 out of 34 cases treated having died at the Arthur Road Hospital, Bombay.

THE ARMY SERVICE EXAMINATIONS.

We herewith print the list of the successful candidates for commissions in Her Majesty's Army Medical Staff and Indian Medical Service:—

ARMY MEDICAL STAFF.		INDIAN MEDICAL SERVICE.

THE EUROPEAN PLAGUE HOSPITAL.

The "Times of India" says:—The number of Europeans born in Europe who have been under treatment in the plague ward of St. George's Hospital between the 13th December 1897, and the 7th of March 1898, was 5 (all males), of whom 2 were cured, 2 remain under treatment, and one died. Of domiciled Europeans 6 were admitted (all males), of whom 3 were cured, 2 died, and one remains under treatment. In the same period 21 Eurasians were admitted (14 males and 7 females), of whom 8 males and 3 females were cured, 7 males and 2 females died, and 4 males and 2 females remain under treatment. Under the heading of European Jews there is one entry, that of a woman, who died. Of Goanese and native Christians 7 were admitted, 6 of whom died.

The percentages of mortality to admissions were, Europeans born in Europe 30 per cent., domiciled Europeans, 33.3 per cent., Eurasians, 42.9 per cent.; and Goanese and native Christians, 85.7 per cent.

SIR RICHARD QUAIN, BART, M.D.

SIR RICHARD QUAIN'S death removes another name from the list of distinguished living physicians. Born at Mallow, on the Blackwater, in 1816, he was educated at Limerick, and migrated to London, joining the medical faculty at University College. Here he served with distinction, building up a reputation which secured for him in 1860 a nomination by the Queen in Council as member of the Senate of the University. He was subsequently appointed Crown representative on the General Medical Council, and member of Earl Spencer's Royal Commission for investigating rinderpest and cattle-plague. For more than thirty years Sir RICHARD QUAIN was Physician Extraordinary to the Queen. He wrote voluminously and edited that standard medical work "A Dictionary of Medicine." Most of the posts of honor in the medical profession have at one time or another been held by him, and his pen was constantly employed in advocating the advancement of medical science.

In these days of negative criticism, which attributes to medical practitioners a certain amount of inflexibility, it is not surprising that the medical profession, as a whole, is not regarded by the public as being in a position to have an opinion on this strange epidemic, which seems to be a violation of the high-fangled notions of that inflexible law of medical etiquette, namely, that duly qualified medical practitioners are prohibited from recommending or prescribing "Secrets" remedies. The *Preventive Medical Journal* says in regard to this matter:—"Secrets" are those whose ingredients are hidden from professional men. These, as such, should never be prescribed by medical men. But proprietary medicines, whose ingredients are openly declared or the elements of which are known to medical men, may with propriety be prescribed."

A NEW USE FOR THE X-RAY.

ACCORDING to the Berlin correspondent of the *Medical News*, a German colleague has suggested the availability of the Roentgen ray in the selection of a bride. The end of marriage being the reproduction of the species, any hindrances to this end which exist, and which may be discovered without subjecting the person concerned to any indignity, he argues, should be found out before marriage. Any insuperable pelvic conformation may thus be easily detected, and he suggests that fiancés should exchange not only ordinary but x-ray photographs, when the preliminary steps to matrimony are being taken. This method, he considers, will be of invaluable service to members of the royal families to whom the birth of an heir is all-important, and the skiagraph of his beloved will be one of the things that a princeling will be supposed to possess before seriously commencing negotiations for her hand.

THE MIDWIFE MUST HAVE HER PLACE.

We take the following from the *Lancet*.—"Midwives, as we have said, are a recognized institution. The public intend to have them and the talk about dispensing with them entirely is idle nonsense, and remains idle nonsense even when based upon elaborate long-division sums to prove that if all the parturient women were divided up by all the names on the Medical Register there would only be an average of so many cases for every medical man. The quotient is uninteresting because all parturient women do not desire male attendants and all medical men do not desire to attend midwifery cases. The intervention of the midwife must be regarded as necessary, upon which it follows that she must be clean and also that she must not usurp the functions of the medical profession, and so endanger the lives of her patients by undertaking work for which she has not received adequate medical and surgical instruction."

MUNICIPAL IMPROVEMENTS OF CALCUTTA.

AMONG the many suggested plans for the site of the new Municipal Buildings for Calcutta, it will be gratifying to the readers of the *Record* to learn that the situation recommended by this journal has been decided upon, and the plan of acquiring the grounds needed for this important sanitary undertaking—for it will be a distinct hygienic improvement of that insanitary region—is precisely the one sketched out by the *Record*. The Municipality deserves considerable credit for its liberal enterprise in this matter, for the total outlay on it is to run into a sum of nearly 7 lakhs of rupees or £10,000. The architectural design of the new offices is by Mr. GUTHRIE, an Anglo-Indian Executive Engineer of the P. W. D., and is worthy of the highest praise.

THE INDIAN MEDICAL COUNCIL ON MEDICAL REGISTRATION IN INDIA.

From the *Indian Medical Record* quoting from the official report of the proceedings of the General Medical Council at Calcutta. A communication was sent from Dr. James R. Wallace, Secretary of the Indian Medical Association, asking for the support of the Council in a proposition that the Government of India should be requested in future to give State appointments only to men whose names are on the *British Medical Register*, and that evidence in courts of law and medical certificates for State or legal purposes should be received only from such persons, or from others whom the State, after due and proper consideration, shall authorize to perform such offices. The Executive Committee resolved that it was not prepared to recommend the Council to take any action in the matter in the absence of any distinct proposal for legislation.

The Indian Medical Association will now approach the General Medical Council with a definite proposal for legislation.

THE SMOKE NUISANCE IN THE CAPITAL OF INDIA.

It is high time, complains the *Statesman*, that something was done to abate the smoke nuisance in Calcutta. Year after year, the air of the metropolis, never in its unadulterated state remarkable for salubrity, becomes increasingly foul, owing largely to the dense clouds of smoke vomited forth day and night from the chimney shafts of the different mills that girdle the city. The pollution of the atmosphere from this cause has reached a pitch which calls for active interference.

IMPORTANT NOTICE TO DEFAULTING SUBSCRIBERS.

OUR Manager regrets being compelled to notify BAD PAYERS by a new method. He is tired of old methods as BAD PAYERS thrive on secrecy. He notifies that subscribers to the *Record*, who have not paid their dues for over three years, will have their amounts notified to them through the *Record* in a regular list. He gives one full month's notice of this threat, which will be put into execution on the 1st May next.

SUIT AGAINST A DENTIST.

A WOMAN recently brought a suit against a New York dentist for injuries to her jaw which she alleged were caused by the unskillful extraction of a tooth by the dentist. She secured a verdict for \$10,000, her case being materially strengthened by the submitting on the part of the plaintiff of a certificate attesting that the defendant had been before convicted in court for practising dentistry without a license.

SHORT ITEMS.

THE *Calcutta Gazette* announces that Dr. James R. Wallace, Editor, *Indian Medical Record*, has been elected by popular vote to the Calcutta Municipal Council, as the representative of Ward 16 in the Calcutta Municipality. This is the largest and most influential European ward in the metropolis, and Dr. Wallace's candidature for it was supported by Dr. William Coulter, Surgeon-Colonel J. O'Brien, the Hon'ble Justice Jenkins, the Hon'ble Justice Amir Ali and several leading English citizens. At the poll he stood second in the voting.

A number of doctors who have been doing duty in the Bombay Presidency in connection with plague have been sent over to Madras for duty. Drs. Beest, Nightingale, Rendell Myler, Husk, Langley, Battis, and Illingworth arrived there on the 18th instant, and are awaiting orders from the Government. One of these has been appointed to the Government Maternity Hospital. Dr. Knapp, who was recently

appointed as Assistant Surgeon, District Hospital, Secunderabad, has been appointed to the General Hospital, Secunderabad, with an appointment.

A "Magnetic Healer" begins her advertisement of her acquirements and capabilities in the following terms: "In order to prove, and being the outcome of the efforts of so many capacities in the new scientific experiments and medical sciences, the vital and heat magnetism as a remedy to a better observation and cure method, will be shown, that this should be realized to the welfare of mankind." The magnetism of her words should almost effect a cure of themselves.

The Civil Surgeon of Shillong (Surgeon-Lieutenant-Colonel R. Neil Campbell), it is understood, is transferred to the Andaman Islands, and the Civil Surgeon of Dushel (Surgeon-Major Dobson) is to be posted to Shillong. Dr. Campbell rendered especially valuable services during the time immediately following the earthquake, when owing to destruction of the water-supply there were many dangers to be guarded against, and an outbreak of typhoid fever was raging in Shillong.

Dr. W. G. Rockwood, Surgeon of the Colombo General Hospital has retired from public service, and Dr. G. H. Thomas assumed the duties of the post temporarily. Dr. Rockwood's retirement from active life, and his absence from the General Hospital, will be keenly felt, more especially by the medical officers at the Hospital and the students, senior and junior, among all of whom he was greatly liked, and by whom his eminent qualities as a surgeon and lecturer were highly appreciated.

Foot-and-mouth disease has broken out amongst the Government slaughter cattle at Peshawar, over six hundred being under treatment. There is also a good deal of mange amongst the transport animals of the Tirah Force, a large number being under treatment in the Field Veterinary hospitals. Anthrax has appeared in Rawal Pindie, where the veterinary authorities are inspecting all private horses and ponies, as well as those belonging to Government.

Mr. P. J. Freyer, M.D., M.Ch., F.R.C.S. (formerly of the N.W. P. and Oudh) has been appointed Surgeon to St. Peter's Hospital for Stone and Genito-urinary Diseases. The rules of this hospital were altered recently, and in future a Master in Surgery of a university, or a Fellow of any College of Surgeons in the United Kingdom will be eligible for election to the surgical staff of the hospital.

The appeal of Dr. Gabanis Demello, who was convicted on the 18th January by Rao Saheb Muzilfer, Special Magistrate, Poona, of defaming Dr. Kody, and fined Rs. 100, in default one month's simple imprisonment, was decided by the Hon'ble Mr. Crowe, District and Sessions Judge. The Judge, finding the charge not proved, reversed the conviction and sentence, and directed the fine, if paid, to be refunded.

The following gentlemen having passed the necessary examinations by the Examining Board in England of the Royal Colleges of Physicians and Surgeons and have been admitted Diplomates in Public Health:—Messrs. Sarnati Darabesth, M.A.C.S. Eng., M.B. and C.M. Abern.; Donald Frederick Dymott, M.A.C.S. Eng., M.B. Lond., Surgeon-Major, I. M. S.

Dr. C. K. Greene speaks highly of the good effects of having hypodermic injections of $\frac{1}{2}$ gr. of morphia in otherwise intractable vomiting. If this and all other possible measures fail, and life is seriously endangered, he suggests intubation of the larynx with a special modification of O'Dwyer's tube. If this be unsuccessful, tracheotomy is the *derrière resort*. The idea, which is supported by experiments on dogs, is that vomiting is impossible if the glottis be kept open.

At a meeting of the Faculty of Medicine held at the Senate Hall on the 18th instant, Dr. Soorjee Coomarr Sarvadhikari was elected President and first representative of the Faculty on the Syndicate in the place of Surgeon-Lieutenant-Colonel G. Bonford. Brigade-Surgeon-Lieutenant-Colonel C. H. Joubert was elected second representative *vice* Dr. S. P. Sarvadhikari, who goes out by rotation on the 30th of April next.

Says Indian Engineering :—"The Report of the Calcutta Building Committee is published, suggesting the formation of a trust, much on the lines proposed in Bombay, for draining streets through congested areas of Calcutta; also recommending the imposition of taxes in jute and railway passengers to furnish the necessary funds. We shall deal more fully with this subject presently."

According to a Bagpore telegram, the Municipal Health Officer of that town was deputed six weeks ago at a meeting of the Municipality to visit India to study plague prevention, but has not yet started. The Municipality wanting the Local Government to supply all the funds which this Government refuses to do.

Surgeon-Lieutenant-Colonel P. H. Benson, the popular chief of the Medical Department in Mysore, contemplates, says the *Mysore Standard*, training half a dozen educated Brahman girls as compounders for the Female Hospital in the province, and we understand that the Government has quite approved of the suggestion.

The Irish Medical Schools' and Graduates' Association held its annual dinner on the 17th March (St. Patrick's Day), at the Café Montec, at 7.15 P.M. There was large attendance to meet the principal guest of the evening, Admiral Lord Charles Beresford, C.B., M.P. Mr. P. J. Freyer, 46, Harley Street, W., is Honorary Secretary of the Dinner Committee.

Surgeon-Lieutenant-Colonel C. J. H. Warden, Principal Medical Storekeeper, Bengal, has been directed to proceed to Bombay immediately to associate himself with Mr. Haffkine in supervising the extended preparation of anti-plague inoculation serum. Surgeon-Captain Johnstone holds temporary charge of the Medical Store Depot in Calcutta.

The sudden and premature death of Jules Péan has left a void in the surgical world of Paris. He was without doubt one of the greatest surgeons of the century, and has, by his advances in abdominal surgery, left behind him an imperishable name. His lectures on clinical surgery, consisting of eight volumes, remain a lasting monument to his memory.

The telegraph from London announces that the double- and treble-barrelled military titles of the Army Medical Staff are to be abolished. The members of that service are to be styled Colonels, Majors, Captains and Lieutenants of the Army Medical Corps. We doubt if the change will prove a blessing in disguise.

The death of Dr. William Sullivan Bostin took place at the Madras General Hospital from pneumonia. Bostin was one of the doctors selected for plague duty, and arrived at Madras last week. Since his arrival, he had been an assistant of the General Hospital. He was only forty years of age.

Surgeon-Colonel Hendley, Principal Administrative Officer in Rajputana, comes to Bengal as Inspector-General of Hospitals, *vice* Surgeon-Colonel Newman, who has been transferred to the Punjab. Surgeon-Colonel Adams from Jodhpur succeeds Surgeon-Colonel Hendley.

Surgeon-Lieutenant-Colonel Sinclair succeeds to the vacancy caused by the expiration of the term of service of Surgeon-Colonel Hunt, Principal Medical Officer, Bangalore, but will retain his present appointment of Inspector-General of Jails, Burmah.

The Government of India has approved of the proposal that when, owing to the exigencies of the service, a medical officer of the rank of Surgeon-Lieutenant-Colonel is appointed Principal Medical Officer of a General Hospital of 500 beds, he be granted temporary brigade rank.

The death is announced at Dera Ghazi Khan on the 22nd March of Lieutenant A. S. Stephen of paralysis. Lieutenant Stephen was the only son of Brigade-Surgeon Lieutenant-Colonel Stephen, late Sanitary Commissioner of the Punjab, and entered the Punjab Commission in November 1895.

Surgeon-Major R. Ross, on special duty in connection with the investigation of malaria and kala azar, begins his researches in Calcutta in connection with the mosquito malaria theory and then continues his investigation with particular reference to kala azar in Assam.

The Court of Appeal has acquitted Dr. Laporte, who, it will be remembered was condemned by the Court of First Instance for having caused the death of a patient in whom he had performed craniotomy. The Advocate-General has in addition withdrawn all accusations against him.

Mr. Haffkine will shortly proceed, in company with Surgeon-Colonel Edward Lawrie, to the plague-infected villages in the Nizam's territory in order to introduce prophylactic inoculations on a large scale.

Malthusian doctrines do not seem to be popular with the London poor. A woman who recently applied for relief to a magistrate in some domestic complications stated that she was the mother of twenty children.

Surgeon-Lieutenant-Colonel D. P. Macdonald, senior medical officer, Port Blair, acts as Medical Storekeeper, Bengal Command, during the absence of Surgeon-Lieutenant-Colonel Warden to Bombay on plague duty.

The proposed trial of vaccination against the typhoid fever amongst British officers and soldiers in this country has, we hear, been negatived by the Secretary of State for War.

Surgeon-Major H. W. Hubbard is appointed to have medical charge of the civil station of Dinapore, in addition to his own duties, *vice* Surgeon-Lieutenant J. G. P. Murray.

Dr. Lustig's serum does not seem to be efficacious. Of 24 patients treated at the Arthur Road Hospital, Bombay, 16 have since died.

We regret to announce the death of Surgeon-Captain J. Walker, M.D., A. M. S., at Jacobabad, of pneumonia, on the 23rd March.

Dr. Godinho, of the Jangseoji Jeejeebhoy Hospital, Bombay, who was admitted into the European Plague Ward, died on the 28th March.

The services of Surgeon-Colonel J. H. Newman, substantive *pro tempore* Inspector-General, Civil Hospitals, Bengal, are replaced at the disposal of the Military Department.

MERCOIR.

Tabs and Syphilis.

In a recent number of the *Berliner Klinische Wochenschrift* EMB contributes an article which has been evoked by the publication of some recent statistics by LEYDEN apparently intended to show that the connection between syphilis and tabs was by no means constant. EMB's views, as is well known, are quite opposed to such a doctrine, and he holds that the connection between syphilis and tabs is a very close, if not a constant, one. LEYDEN's figures are analysed by his pupil STORSEBOM and they comprise 106 cases. Of this number 69.4 per cent. are said to have developed tabs without any preceding syphilis. EMB criticises these figures, pointing out that the number considered is far too small for statistical purposes, and further that 52 of the cases—33 women and 19 men—are cases occurring among the lower classes. As is generally recognised, negative evidence of the occurrence of syphilis in the lower classes, or of its occurrence in women of any class, is not to be relied upon. EMB himself adduces evidence gathered from a consideration of 200 cases of tabs occurring among men in the upper classes. Of these 15 had no evidence of infection, 123 had had undoubted secondary syphilis, while 62 had had chancres but no secondary symptoms. Of the 62 who had only chancres 25 had either an undoubted hard chancre or had been subjected to anti-syphilitic treatment on account of the suspicious character of their condition. Further, of the 15 in whom there was no evidence of syphilitic infection 11 could not be regarded as above suspicion on account of the occurrence of one or more attacks of gonorrhoea in some, repeated miscarriages by the wives of others, and such like, so that out of the 200 cases there were really only 4—i.e., 2 per cent.—in whom syphilitic infection could, as far as that is usually possible, be excluded. If any further proof were needed of the close dependence of tabs on syphilitic infection, we venture to think that these statistics of EMB will furnish it.—*Lancet*.

Diagnostic Importance of Exact Pulse Examinations.

W. JANOWSKI deprecates the modern tendency to regard lightly the information to be obtained from the pulse, and attaches much importance to the results obtained by an intelligent use of the sphygmograph. He recognizes eighteen forms of arterial pulse, which are to be grouped as follows.—(A) Pulse whose characteristics are recognizable from the inspection of tracings of a single beat. 1, Pulsus durus; 2, pulsus mollis; 3, pulsus celer; 4, pulsus tardus; 5, pulsus magnus; 6, pulsus parvus. (B) Those forms which require for their recognition tracings of a succession of beats. 7, pulsus frequens; 8, pulsus rarus; 9, pulsus irregularis; 10, pulsus embryocardia (a rapid, short systole, followed by an equally rapid and short diastole, the pause being altogether lacking); 11, double pulse, in which each beat is closely followed by another, a pause then intervening before the next beat (triple and quadruple forms are also found); 12, unequal pulse, characterized by unequal height of the wave summits; 13, alternating pulse, in which small waves succeed larger ones in a definitely proportionate manner; 14, the so-called pulsus paradoxus, in which the character of the single waves is influenced by respiration; 15, alternating form of double pulse, in which the first of the two beats is larger than the second; 16, hemistaltis, two heart beats giving rise to but a single pulse; 17, condition of total arrhythmia, presenting differences in size and rhythm not governed by any rule perceptible; 18, pulsus differens, a

pulse different in the two halves of the body. Each of the above is exhaustively but practically treated, and the value of the discussion is furthered by numerous reproductions of pulse tracings taken at the bedside.—*N. Y. Med. Rec.*

For Infantile Constipation.

CARRIERS, in speaking of infantile constipation, says that the alimentation should first be attended to. If the child is on the breast, the number of nursings is probably at fault; or, it may be necessary to prescribe exercises for the mother. At the period of weaning arrowroot and other preparations of a somewhat laxative character will be of service. A little soup, preferably that of chicken, with tapioca, or bits of bread may also be given. In other cases, massage, laxatives, or suppositories may be employed. Massage is practised as follows:—Every morning the palm of the hand is oiled with vaselin, and with it circular motions are made around the umbilicus, beginning in the right iliac fossa. The pressure should be light, and the whole treatment should not exceed ten minutes. After the first year the massage should follow the course of the large intestine. As laxatives, the author recommends castor oil and magnesia. In order to secure an immediate evacuation injections or suppositories may be used. Injections should not be larger than 2 ounces during the first six months, and 4 ounces after the first year. Boiled water, a weak solution of camomile, or water with a spoonful of oil of sweet almonds may be used.—*Med. News*.

Don'ts in Heart Disease.

Don't feel called upon to give digitalis as soon as you hear a murmur over the heart. Study and treat the patient, not the murmur.

Don't conclude that every murmur indicates disease of the heart.

Don't forget that the pulse and general appearance of the patient often tell more than auscultation.

Don't neglect to note the character of the pulse when you feel it. Possibly you may look at the tongue to satisfy the patient; feel the pulse to instruct yourself.

Don't think every systolic murmur at the apex indicates mitral regurgitation; every systolic murmur at the aortic interspace, aortic stenosis. The former may be trivial; the latter may be due to atheroma of the arch of the aorta.

Don't say every sudden death is due to heart disease.

Don't forget that the most serious diseases of the heart may occasion no murmur. A bad muscle is worse than a leaky valve.

Don't examine the heart through heavy clothing.

Don't give positive opinions after one examination.—*Phil. Med. Jour.*

Intussusception: Nine Inches of Gut passed per Rectum.

LAURENT and FALEY record a fatal case of intussusception, the patient apparently refusing operation. A woman, aged 33, had feverish symptoms, headache, and gastric trouble for a few days, when suddenly acute obstruction set in. There was intense pain in the right iliac fossa, where a tender, elongated tumour could be felt. Appendicitis or intussusception was diagnosed. At the end of a fortnight the feverishness abated, and spontaneous diarrhoea set in, the abdomen previously much swollen became flat. Nine days later a very foetid stool was passed, and in it was found a sloughy mass 25 cm. (9½ inches) long. It consisted of ileum with part of the cecum. For a week the patient did well, then vomiting and foetid diarrhoea set in, and death occurred a few days later. No mention of any necropsy is made. LAURENT and FALEY observe that this is not the first case where the free elimination of the intussuscepted gut was not followed by ultimate recovery.—*Brit. Med. Jour.*

OPHTHALMIC SURGERY.

By C. C. GILLES, M.B., M.S.

Professor of Ophthalmic Medicine and Surgery,
Lahore Medical College.

Treatment of Trachoma.

HAVING regard to the great importance of the subject, I quote in extenso the following taken from the *St. Petersburg Medical Journal*—

"The granular inflammation of the lids, or trachoma, is a disease the treatment of which has, to say the least, been most unsatisfactory hitherto. Some time ago, when various operative measures for the removal of the characteristic follicles were introduced, many were sanguine as to the results which would follow such treatment. Most of those who have large experience of it cannot, however, boast of much success. A couple of years ago, Dr. NENAMOFF, of Charkow, published in Russia, where trachoma is in many parts a common affliction, a method of treatment with iodine solutions, with which he professed to be able to cure the disease. In the August number of the *Centralbl. f. prakt. ophthalm.*, LEIPZIG, he gives full directions as to the manner in which he carries out this treatment. The results which he, and others in Russia, claim to have obtained certainly appear to be astonishingly good. If they should be confirmed in other countries, this new method must be looked upon as a very important advance in ocular therapeutics. JAKOWLEFF, an army surgeon, treated 144 cases of trachoma by NENAMOFF's method, and came to the conclusion that by its continued use every form of trachoma can be cured. After referring to this and other confirmations of his assertions, NENAMOFF remarks: "The observations of LEBER, SAWOTTSCHINSKI, JAKOWLEFF, and myself show that iodine does not belong to the category of pharmacoeutic means, which, having been proposed and tried, are soon abandoned, either because they are of no value or because other measures give equally good palliative results. The rapid healing of trachoma, when the cicatricial stage has not yet been reached, and the marked improvement in the very worst cases, sufficiently show that the iodine treatment deserves special attention." Iodine, he points out causes the absorption of lymphoid elements, as shown by the daily experience of its use in follicular catarrh of the pharynx and in the hyperplasia of lymphatic glands. It is, besides, a powerful antiseptic, which even in weak solutions (1:500) destroys the most resisting micro-organisms. The use of iodine in the shape of tincture, which contains 90 per cent. of pure alcohol, is dangerous in conjunctival disease, as it is apt to injure the cornea. The solvents of iodine, besides ether, which is too volatile, are glycerine and white vaselin oil. The latter is sufficiently penetrating, and does not cause irritation. In both glycerin and white vaselin the iodine is soluble to the extent of 1-5 per cent. To increase its solubility, alcohol may be added to glycerin, or ether to vaselin.

Trachoma consists of a lymphoid infiltration of the adenoid tissue of the conjunctiva, with the formation of follicles which are retiform in their structure and mostly provided with capsules. In the course of time the contents of these follicles necrose and are absorbed. The cicatricial formation is the result of the irritation which accompanies the development of these new bodies in the conjunctiva. Without doubt the primary cause of the development of the trachoma follicles is a microbe one. Where the soil is suitable the microbes quickly multiply, and cause a rapid development of lymph follicles. In other cases the follicles develop slowly but progressively, while at the same time a hyperplasia of the papillae takes place, and a destruction of epithelium from the invasion of leucocytes. A similar growth of lymph follicles, with the formation of new vessels, characterizes the

accompanying pannus. The treatment of the disease of the lids the averted conjunctiva, with a 1 per cent. iodine solution of iodine cases or trachoma, taking care to protect the cornea, and, if necessary, holding the conjunctival surface. The solution is applied with a piece of absorbent cotton-wool. The lids are kept closed for some moments after the application, until the yellowish or brownish coloration has disappeared. If this is tolerated, the strength of the solution may be gradually increased up to 6 or 4 per cent. The fresh follicular forms of trachoma treated in this way can, according to NENAMOFF, be cured, without the occurrence of any cicatrization, in from three weeks to three months, depending upon the severity of the attack. In cases of papillary trachoma, in which the conjunctiva is covered with warty granulations and the tarsus markedly thickened, the prognosis is less favourable, not only in respect of a complete *restitutio ad integrum*, but as regards the rapidity of the cure. Yet pretty satisfactory results are to be got in such cases by the use of a 2 to 3 per cent. solution. In a short time the follicles are reduced in size, and the conjunctival surface assumes a more squable velvety-looking character. The frequent accompanying pannus and corneal ulceration of these cases is no contra-indication to the use of the remedy. On the contrary, it leads to a rapid clearing up of the corneal opacity. In pannus crassus the iodine solution should, in fact, be applied directly to the cornea. The iodine should, however, not be used when the trachoma is in the stage of inflammation and the conjunctiva swollen and oedematous. Immediately after the subsidence of these symptoms, and when the follicles make their appearance on the surface of the conjunctiva, the same treatment should be begun, using at first weak ($\frac{1}{2}$ per cent.) solutions and gradually increasing their strength.

Nux Vomica in the Treatment of Insufficiency of the Ocular Muscles.

In an interesting editorial, the *Therapeutic Gazette* for 15th November 1897, summarises the recent observations which have been made upon the signal benefit which follows the administration of nux vomica in ascending doses in cases of muscular insufficiency. MÜSSER's experience, that the dosage of nux vomica is in inverse proportion to the age of the patient is of importance, inasmuch as it shows that this drug can with perfect safety be administered in full doses to children who are so often the subject of insufficiency; in one of MÜSSER's cases as many as 200 drops, three times a day, were well borne. The presence of retinitis or of retinal irritability, as has been pointed out by DR. SCHWENITZ, is a contra-indication to the use of nux vomica in full doses. It is, of course, not to be forgotten, that any existing error of refraction is to be accurately corrected by means of spherical lenses properly decentered or used in conjunction with prisms if necessary.

Relation of Intra-Ocular Circulation to Glaucoma.

SULZER, as a result of the study of a series of special cases, divides glaucoma into three classes; circulatory, vascular, and nervous, and maintains that all these are in the first instance due to vascular degeneration. In the vascular group the degeneration is primary; in the circulatory group it is caused by the disturbance of equilibrium between the intra-ocular and arterial tensions; whilst in the nervous group it is to be traced directly to a nerve origin. According to SULZER, the cupping of the disc which is so characteristic of glaucoma, and which is ascribed by the general body of ophthalmologists to the direct mechanical effect of increased intra-ocular tension is primarily due to degeneration of the myeline fibres from malnutrition—the defective or insufficient nutrition itself being dependent upon disturbance of the retinal circulation. If these views are proved to be correct, much greater attention will have to be paid to the intra-ocular circulation than seems to be the case at present, if the treatment of glaucoma is to be conducted on rational lines.

the case of *Peritonitis in Labor*, used the *chloroform* afterwards.

From the study of unrecorded clinical experience, HARRIS offers the following deductions: He insists that the condition of the patient before delivery should be accurately known, in order that all of her secretory and excretory organs may be properly regulated. If leucorrhoea exists, hot douches, medicinal and rectal, should be employed. If the patient be a primipara of advanced years, massage of the perineum and vulva before and during labor will be beneficial. During labor the physician should keep informed by educated touch as to the dilatation and degree of dilatation of the outlet. When labor is normal in every respect, the perineum will need little or no support, but the palmar surface of the hand should be ready to furnish support, should it be needed. When the perineum yields slowly and irregularly, the hand should be ready to give support at any moment, and this support must be given in a proper manner during the least expulsive pains. Chloroform should be employed freely and the woman exhorted not to bear down. In case of rupture, an immediate operation for repair should be undertaken, but for the purpose of determining the fact of a rupture it should not be necessary to subject the woman to indelicate and needless exposure. If educated touch cannot detect laceration, then repair is not needed. If doubt exists with regard to a laceration, careful inspection of the parts should be made. Slight fissures and abrasions do not need sutures. More harm may be inflicted with sutures by invasion of the deeper structures of the canal than good effected by closing these rents in the mucous membrane of the vagina. No other antiseptic is needed in primary operations than water, which should be boiled and used as hot as can be borne by the patient.—*N. Y. Med. Rec.*

Chloroform in Obstetrics.

THE following propositions may be advanced: 1 The most recent experimental study indicates that the evil effects of chloroform result from vasomotor paralysis, causing the accumulation of blood in the abdominal viscera especially, and bringing about partial or complete cessation of function in the nervous centres from acute anæmia. 2 Pregnancy increases vasomotor tensions, and thereby renders the pregnant woman less liable to the injurious effects of chloroform. 3 In normal labor, the actual expulsion of the child may be safely rendered painless, dilatation of the birth canal furthered, and laceration diminished, by light and transient narcosis from chloroform. 4 In tetanus of the uterus, eclamptic convulsions, and maniacal labor, chloroform is to be preferred to ether, and is most useful. 5 Profound narcosis from chloroform is seldom if ever necessary in obstetric practice, and, like this condition under ether, is attended with risk.—*E. P. DAVIS, N. Y. Med. Rec.*

Puerperal Tetanus.

RUBSKA describes at length 6 unpublished cases of tetanus in childhood. All ended fatally, and in all definite organic lesions were detected. He also notes 8 other cases recently published by PIRSK in a paper written in the Bohemian language, these were also all fatal. RUBSKA issued in 1890 an earlier report of 11 cases, none of which recovered. He notes, however, IRVING's case where tetanus set in on the eleventh day after delivery, remained acute for a fortnight, and then passed slowly off, the patient ultimately recovering. The earliest date for the onset of tetanus is the sixth, the latest the eleventh day. It begins in puerperal cases by trismus and dysphagia, and not by tetanic contractions of muscles near the pelvis. Narco-

sis, antispasmodics, and warm enemata, as well as, in some cases, immediate extirpation of the uterus, proved unavailing in the 20 fatal cases collected by RUBSKA. He discusses the bacteriology of this form of tetanus. HAYAN has shown that streptococcus infection does not predispose to secondary infection of the genital tract by the tetanus bacillus.—*Brit. Med. Jour.*

Decidua Maligna.

LOHNSBURG and MANNHEIMER, place under this category two cases under their own observation. The first was described many years ago as epithelioma following pregnancy. The patient was a multipara, aged 38. One November she was delivered at term with forceps. Two months later, metrorrhagia having continued for four weeks, an examination was made and a mass of fibrin discovered. In January the cervix was dilated, and a tumour of the size of an almond removed by the curette from the anterior wall of the uterine cavity. The bleeding grew worse, and masses of a spongy substance were expelled, and it was noted that they resembled decidua. Emaciation became marked, and the patient died six months after delivery. Cancerous growths were found in the lungs, liver, spleen, kidneys and abdominal lymphatics. The uterine growth appeared under the microscope as "of the usual structure seen in epithelial cancer." The second patient was 42. On 19th November 1893, her third confinement ended at the fourth month, a large vascular mole being expelled. Seven weeks later metrorrhagia set in. For nearly two years the bleeding went on. The body of the uterus was as large as a fist, and metastatic deposits were found in the vagina. On 18th October 1897, the uterus was removed. On the 30th of the same month the metastases in the vagina were excised. The microscopic appearances corresponded to what is usually termed decidua tissue. On 1st April 1898, the patient was in good health, with no sign of local or general recurrence or diffusion of the new growth.—*Brit. Med. Jour.*

Technique of Vaginal Section Irrespective of Hysterectomy, for Diseased Appendages and Small Pelvic Tumours.

ANYTHING that lessens shock reduces the mortality in operations and shortens convalescence, but though he thinks that vaginal section will scarcely supersede abdominal section, Dr. AUGUSTIN H. GOMBERG claims the following advantages for the former over the latter: (1) More ready consent of patient to vaginal section and consequently earlier removal of hopelessly diseased organs and less mortality than in the graver operation of abdominal section. (2) Less risk, by a long way of peritonitis and ready means for removal of diseased conditions that would not warrant the gravity of abdominal section. (3) Safe exploration of pelvis to clear up diagnosis when the diseased condition is not extensive and the adhesions neither dense nor numerous. (4) More satisfactory and perfect drainage, and (5) quicker complete union of the incision and a rapid uneventful recovery. Vaginal section is preferably applicable for—(1) Small, solid or partly solid pelvic tumours. (2) Cystic or otherwise enlarged and diseased ovaries. (3) Ovarian cysts of considerable size can be evacuated of their fluid contents and their sacs withdrawn through a very small vaginal incision. (4) Hemato-hydro or pyro-pelvis. (5) Removing small subperitoneal fibroids by myomectomy. (6) Draining pus accumulation low down in the pelvis. (7) Hematoma and hamatocoele involving ectopic gestation, and (8) pelvic exudations which resist other means for their removal.—*Jour. Amer. Med. Assoc. and N. & S. Reg.*

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.

Relation between the Testicle and Prostate.

FLOREANU says that an extirpation of a single testicle is often followed by atrophy of the corresponding side of the prostate gland, it must be due to some nerve relation between the two rather than to any altered internal secretion. Removal of both testicles before maturity interferes with the full development of the prostate. That castration after full maturity will reduce a normal prostate is in dispute. If it does so, it reduces the volume and elasticity of the organ, and increases its consistency. The effect of complete castration in beginning, or fully developed hypertrophies, is irregular, and often not demonstrable. The reduction in volume is sometimes confined to the upper part of the prostate, and is accompanied by a loss of elasticity; while in others a shortening of the urethra is noticeable. Tuberculous processes in the gland may be brought to a standstill, or even cured, by castration.

Unilateral castration sometimes produces in the corresponding side of the normal adult prostate such changes as have been above described. It will not prevent future hypertrophy. Its effect on existing hypertrophy is slow, and consists in a shrinkage of the corresponding side, especially in the upper portion of the gland. It may cause healing of tuberculous lesions. Unilateral castration is not followed by a demonstrable reduction in size of the opposite lobe of the prostate. There usually results atrophy of the seminal vesicles, with compensatory hypertrophy of the other testicle (and prostatic lobe?). The advantages of double over unilateral castration are, therefore, plain.—*Med. News.*

Physiological action of Massage on Glandular Secretion.

COLOMBO experimenting on dogs with gastric and biliary fistulae, has estimated the effect of massage on the amount and quality of the gastric juices, bile, and renal secretion. He found that as regards the gastric juice, the quantity which came through the fistula in the space of two hours was more than double that which flowed without massage. Massage for five minutes made no difference, but when continued for fifteen minutes the secretion reached its maximum; if continued longer, the amount remained about the same, but the quality was poorer. As regards the bile, the best results were obtained by ten minutes' percussion followed by ten minutes' friction and kneading. Ten minutes' abdominal massage also increased the amount of urine; slight traces of albumen were observed in the first few minutes after massage, but this was only transitory. In each case the watery part of the secretion was increased out of proportion to the specific elements. This suggests that the observed increase is largely due to a greater flow of blood and better filtration in the various organs concerned.—*Brit. Med. Jour.*

Fusion of the Kidneys.

MESCHINET DE RICHMOND exhibited at a recent meeting of the Bordeaux Anatomical Society a specimen in which the kidneys were united, not by their upper ends into the rarely seen horseshoe kidney, but by their lower extremities into the more common crescentic form. The author believes the greater frequency of fusion of the lower renal extremities to be due to the oblique position in which these organs normally lie with their lower ends approximated. The specimen came from a negro, 24 years of age, and had given rise to no symptoms of inconvenience during life. The point of union was at the sacro-lumbar articulation, and was marked by great thinning out of the renal tissue.—*Brit. Med. Jour.*

Pathology of Multiple Sclerosis.

As he had observed hyaline granules with central gliosis and multiple sclerotic foci, the first symptoms of which could actually be traced back to childhood, Professor SEIZEN-PRIG discards the toxic theories of OPPENHEIM and disagreeing with MARINI's view of its being, in most cases, a sequel of acute infectious diseases, expresses his candid opinion that multiple sclerosis mainly depends upon some congenital abnormality in the nervous system. He also calls attention to (1) the character of the disordered movement which does not essentially differ from the ataxy of tabes, and (2) the frequent absence of the abdominal reflex, as two important conditions in the symptomatology of the disease.—*Pac. Med. Jour.*

Pathology of Appendicitis.

SHOWING that appendicitis develops through the following stages: (1) catarrhal inflammation of the living mucous membrane with (2) hypertrophy of muscular and mucous coats and irregular narrowing of calibre, (3) strictures, (4) imprisoning food, desquamated epithelium and pus-forming concretions, (5) to produce obstruction, distension, perforation and abscess. Dr. ROBERT ARNOLD assigns three distinct causes for the obstruction that may lead to ultimate gangrene, perforation or rupture: (1) catarrhal inflammation followed (as in the urethra) by stricture, (2) microbial ravages, (3) A flexure from an abbreviated point in its mesentery may arrest the fecal contents such as epithelial scales, pus and starch cells, shreds of meat fibre, bacterial debris, &c., which become inspissated and grow into a concretion which becoming a source of irritation leads to pus formation.—*Med. Rec.*

Serum Diagnosis of Enteric Fever.

LEVY and GRADLER describe their method of carrying out WIDAL's test. The typhoid bouillon culture should not be older than ten to twelve hours; otherwise there is danger of a pseudoagglutination. The authors maintain that fluid serum should be used in preference to dry blood. An observation period of two hours is sufficient. In a typhoid epidemic the serum reaction gave a positive result in 105 out of 115 cases. The authors investigated these cases in such a way that one of them made the bacteriological examination and the other the clinical, and then they compared notes. All the 105 cases showed the clinical characteristics of enteric fever, whereas the remaining 10 did not. When it is considered how difficult it is to exclude errors of diagnosis in an epidemic, the value of the test becomes obvious. Two cases were particularly instructive. The diagnosis lay between enteric and puerperal fever. In the one case the patient was admitted after fourteen days' illness, and WIDAL's test was positive. Besides a puerperal endometritis, the characteristic lesions of enteric fever were found after death. In the other case the patient was sent in with the diagnosis of enteric fever, but the reaction was negative. At the necropsy, a puerperal endometritis was found, but no lesions of enteric fever. A table is appended showing the details of the various cases. In none of the genuine cases did the reaction fail. The serum reaction enabled them to distinguish between diseases with symptoms resembling enteric fever and the abortive forms of the disease itself. In 10 of the 18 cases it made the diagnosis possible in the first week; of the remaining 8, 5 were not enteric fever, and 3 gave the reaction later. Of 26 examined in the second week of the illness, the reaction was positive in 22, and the remaining 4 proved not to be typhoid. Of 16 in the third week, 24 were positive, and the remaining 3 turned out not to be typhoid fever; 16 examined in the fourth week, 18 in the fifth, 7 in the sixth, 10 in the seventh, and 5 in the eighth all gave positive results, and the disease presented the characteristics of enteric fever.—*Brit. Med. Jour.*

FURIES AND DOMESTIC HYGIENE AND CONSERVATION.

Recent Researches on Immunization.

Dr. WASSERMANN, assistant to Professor KOCH, and Dr. TAKAKI, of Japan, have published an interesting article on immunization in the *Berliner Klinische Wochenschrift* of 3rd January. In an essay on diphtheria antitoxin Professor EHRICH has suggested that infective diseases are due to the affinity of certain cells for the specific virus, tetanus, for instance, being the result of the tetanic virus entering into combination with the cells of the spinal cord. According to the same theory the substance of these cells, which he terms "toxofore Seitenketten" (toxofore cells), is rendered soluble in the process of immunisation and enters into the circulation so that the antitoxin of tetanus consists only of the medullary cells in a soluble form. Dr. WASSERMANN concluded that if this theory of Professor EHRICH were true the normal spinal cord must contain antitoxic substances and that it might therefore be possible to immunise an animal against tetanus by injections of spinal substance. Dr. WASSERMANN and Dr. TAKAKI having accordingly made an emulsion of the cerebral and spinal substance of healthy animals with the aid of a solution of sodium chloride, injected it together with tetanus toxin into white mice and succeeded in ascertaining the remarkable fact that the spinal and especially the cerebral substance both of the human subject and of guinea-pigs, rabbits, horses, &c., has a strong antitoxic action against the tetanus toxin. It neutralises the virus and will even save the life of an animal if injected several hours after inoculation with infective matter. Dr. WASSERMANN and Dr. TAKAKI are of opinion that the spinal and cerebral cells of the injected substance by their affinity for the tetanus toxin prevent it from invading the central nervous system. They propose to designate this new method of immunisation as "Seitenketten Immunität" and they point out that their researches, although of theoretical interest, do not seem to be available for practical use. The paper is accompanied by a detailed description of the experiments.—*Lancet*.

Sanitary Care of Canned Foods.

Dr. T. BROWN, at the Sanitary Congress at Leeds, avowed himself to be a strong advocate of legislation in the matter of canned foods. In regard to tinned fruits Dr. BROWN said, he had not heard of any case which had ended fatally. He had, however, made numerous analyses showing that in cans in which lead was used in tinning or soldering, the former metal was found in the fruits and syrup. How long foods hermetically sealed would keep was not definitely known. Having had canned foods, including meats, soups, rabbits, gables, and oysters from twenty to thirty years, he had found that the tins, though rusty outside, were perfectly good inside. The meats were sound, though not as fresh and tempting to the eye as recently prepared samples. In canned fruits, however, the effect of age was that the acids of the fruits dissolved, by chemic and galvanic action, the plating and solder with disastrous consequences. To safeguard the public health, Dr. BROWN recommended the government to forbid tinned foods in which tin used for plating contained more than 1 per cent. of lead or more than 10 per cent. in solder, the same law in fact which had been in force in Germany since 1889.—*Jour. Amer. Med. Assoc.*

Physical vs. Mental Health.

We cannot deny the facts of physiological psychology. Consciousness depends on the condition of the brain. Drugs may modify character. Insanity may be produced by physical conditions. The decay of mind leaves no part of con-

sciousness free. The way to meet this class of facts is not by denial. While we believe that consciousness depends on the brain and on health, an equally significant fact is that the bodily state depends upon the consciousness. The impressive thing is that bodily health is chiefly related to a state of mind. It is rather more true that digestion depends upon feeling well, than that feeling well necessarily depends upon digestion. If it is true that a red-hot iron burns the flesh, it is also true that burn wounds have been produced by hypnotic suggestion. It is a reciprocal chain—mind and body are both correlated in both directions.—*Med. Brief*.

Distinction of Raw from Boiled Milk.

ALTHOUGH this question possesses but little direct relation to clinical chemistry proper, yet as processes for treating milk are now largely used, it will be of some interest to know that it is possible to determine whether it has been sterilized, that is, heated to the boiling point, or only pasteurized. E. DUPONT, a French chemist, recently published several tests which will distinguish between raw and boiled milk, giving distinct color reactions with the former and none with the latter. I have repeated these tests with entire satisfaction, and have also found that the photographic developer called amidol may be used, although the reaction is not so striking as with the substances DUPONT indicates. The best test is a synthetic coal-tar product which rejoins in the name of para-diamidobenzene. When a solution of this is added to a little raw milk and followed by a few drops of hydrogen dioxide solution a deep blue is at once produced. I have found that the action is still produced if the milk be heated to 170°F., but ceases if it be heated to 180°F. I intend to test some of the milk which is now offered for sale as pasteurized.—*Phil. Poly.*

Boil the Water.

EVERY physician should so advise the families under his care. Let sufficient for the day's supply of drinking water be boiled in the morning and set in a cool, clean place in clean covered jars. It should never have ice added to it, either in summer or winter. The supply of milk should be similarly treated. In this way much disease can be prevented.—*Phil. Poly.*

Control the Wet Nurse.

SINCE URNIKOFF has demonstrated that ammonia added to human milk causes a dark red color, varying with the amount of reagent (one drop of a ten-per-cent. solution added to five cubic centimetres of milk causing a violent hue), and that the longer the milk has been flowing the more intense is the reaction, we are in a position scientifically to verify a nurse's statements as to the length of time since her confinement.—*N. Y. Med. Rec.*

Important Legal Decision: Water-Companies Liable for Damages for Impure Water.

IN Wisconsin, a man died of typhoid fever. The widow sued the Ashland Water Company and won her suit, receiving \$5,000 damages. The court held that water-companies are responsible for damages resulting from the use of the unwholesome water; they provide. We believe this decision is an epoch-making event, and are most heartily glad of its occurrence. If it should be plain that typhoid fever and other infectious diseases in any or in many cases, have been due to the water supplied by the companies, private, urban, or governmental, those who have been afflicted, if they recover, or their relatives, if the patients die, should at once institute legal proceedings, and press the suit to a conclusion. The same law must, of course, apply to those supplying diseased milk, meat, etc. Touch the pocketbook and the reforms that have been impossible through the politicians and selfish interests of those concerned will at once, and as if by magic, be effected. The dollar is more powerful than humanitarian motives.—*Phil. Med. Jour.*

Therapeutic Treatment of Malaria.

The British has recently published in the *Lancet* a paper stating the his Doctor's degree of success in the treatment of malaria by the serum of patients. Summing up the experience of the last year he states that the results in this form of treatment have been most striking, some regarding the treatment of malaria by offering the patients of serum, but some regarding the serum while other physicians have been in doubt as to whether the results and consider the results of the serum as being more or less. Dr. Hume's method consists entirely from those formerly employed in that he removes the serum from which the serum was taken by means of a glass of mercury until certain signs of maceration of the serum themselves. Twelve patients suffering from syphilis received a series of injections of blood serum taken from the macerated horses. The results were not favorable. The patients lost in weight with few exceptions; the disappearance of symptoms when it occurred was only temporary; the blood in every case was found to contain a diminished number of red and white corpuscles, the hemoglobin was lessened in quantity, and the specific gravity of the blood fell below the normal. The injections were sometimes accompanied by unpleasant symptoms, such as gastric disturbance, pains of various kinds, erythematous rashes, and some rise in temperature, consequently Dr. Hume is unable to regard the serum of macerated horses as a promising method of treating syphilis. —*Lancet*.

Method of Concentrating Therapeutic Serum.

BURWIS has experimented with diphtheria and tetanus antitoxin preparations in order to obtain concentrated solutions. The dried preparations are unreliable and under certain circumstances may be dangerous. Partial evaporation of serum at a low temperature gives a curdy product. A better method consists in freezing the remedy. The ice is clear and there remains only a small amount of a brownish fluid in the bottom of the glass. If the glass of serum is allowed to thaw slowly the upper layer is without color and contains little besides pure water. —*Med. News*.

Serum Treatment of Scarlet Fever, Measles, Pneumonia, and Erysipelas.

HUMPHREY and BLUMENFELD have experimented with the blood of persons convalescent from these diseases. Blood drawn from the vein of the elbow, the serum was mixed with an equal amount of physiological solution of salt, one per cent of chloroform was added, and the mixture was passed twice through a Bankhead filter. The serum was used in thirteen cases of scarlet fever, nine of measles, fourteen of pneumonia, and six of erysipelas. It mitigated and shortened them all, but did not hasten defervescence in the cases of pneumonia. —*N. Y. Med. Jour*.

Therapeutic Agents; Beer Yeast in Diabetes.

THE diet can be varied in diabetes if two or three table-spoonfuls of beer yeast are taken during the day at meals, digested in beer or white wine. It promotes assimilation and destroys the sugar derived from the food, while preventing the accidents that follow an excessive meat diet. It is especially useful in cases in which the sugar is chiefly derived from the food, but is beneficial in all. It should be discontinued for a few days from time to time to see when every three or four days. —*Jour. Amer. Med. Assoc.*

The injections were sometimes accompanied by unpleasant symptoms, such as gastric disturbance, pains of various kinds, erythematous rashes, and some rise in temperature, consequently Dr. Hume is unable to regard the serum of macerated horses as a promising method of treating syphilis. —*Lancet*.

Peppermint-water.

Peppermint-water ... 10
Fruit spirit ... 10
Lamp sugar ... 10
Dissolve the sugar in the peppermint-water and stir with the spirit. A pale green color is usually given by tramping a few blades of grass with a little of the spirit, and adding a sufficiency to impart the desired tint.

Ginger-beer.

Essence ginger ... 10
Tincture orange-peel ... 10
Essence vanilla ... 10
Rectified spirit ... 10
Syrup ... 10
Distilled water ... 10
Mix and filter bright, color with burnt sugar. —C. & S.

Tuberculous in Children.

R Balsam peruviani ... 10
Oleum jecoris aselli ... 10
Gummi arabici ... 10
Aqua destillata ... 10
Syrup aurantii cortidis ... 10
M. S. Teaspoonful every two hours after meals. —SCHNEIDER.

Prickly Heat.

R Spiritus aetheris nitrosi ... 10
Magnesi sulphatis ... 10
Oleum cajuputi ... 10
Syrup tolutani ... 10
Liquoris magnesi carbonatis ... 10
M. S. Teaspoonful thrice daily. —GODDARD and STARR.

Mueller's Tooth Wash.

ACCORDING to the *Centralblatt für die gesamte Therapie* for October, it is composed as follows:—

R Thymol ... 1 part
Benzoic acid ... 12 parts
Tincture of eucalyptus ... 10 parts
Alcohol ... 100 parts
M. S. A teaspoonful to be diluted with half a wine-glassful of water.

Severe Eruptions.

R Ammonii chloridi ... 10
Ammonii carbonatis ... 10
A dose in water.
Or:
R Ammonii chloridi ... 10
Liquoris hydrargyri ... 10
Spiritus chloroformi ... 10
Infusio gentianae ... 10
M. S. Teaspoonful in wine or aqua. —K. SWARTZ.

Presumptive Eruptions of the Skin.

THE *Journal de Medicine de Paris* for 1884 September gives the following formula:—
R Conserva cutanea ... 10
White sugar ... 10
The whites of one egg ... 10
Lemon-juice, about ... 10
Distilled water ... 10
To be applied every morning and allowed to dry.

THE WARRANT OFFICERS' TRAVELLING ALLOWANCE: A QUESTION OF OFFICIAL INDEPENDENCE AND OF THE CHANCE OF ABUSE.

By Mr. Justice, "The Hindu Medical Officer."

THE principle laid down by the Indian Government of "recognising and supporting all officers—without distinction of honorary or merely officiating—in the exercise of their positions, no matter what their actual rank may be," is rigidly maintained in every department of Government. It was hitherto applied to us, still, No. 2892 S. B. Government of India, Finance and Commerce Department, dated Simla, 2nd July 1897, deprives Military Assistant Surgeons, appointed Civil Surgeons of Districts, of the privilege they have, and once enjoyed the right to, by ruling that only Warrant Officers of the first class can draw first class travelling allowances while Warrant Officers of the second class must travel at second class rates.

This unkind ruling particularly affects 38 members of the I. S. M. D., all the Warrant Officers of which are second class; but according to Articles 157 A and 1096 Civil Service Regulations, travelling allowance at first class rates is permitted to all officers who hold appointments, the maximum pay of which exceeds Rs. 500 per mensem, and except in the case of Assistant Surgeons, 2nd class, the scale of pay for Warrant Medical Officers holding civil medical charge of districts is similar to that laid down for officers of the Unconvenanted Indian Medical Service (who rank as first class for travelling allowance) and ranges from Rs. 350 to Rs. 700 per mensem. Therefore to now relegate them to second class rates of travel which apply to Warrant Medical Officers in subordinate positions is to undeservedly degrade and humiliate them.

Indians are very quick to notice and take advantage of a slight, however trivial it may be or seem, and if through insufficient travelling allowance he has to journey by rail or steamer in company with clerks, head constables and other subordinates attending the District Superintendent of Police and the Magistrate, with both of whom he has to be in daily communication, how can a Warrant Medical Officer, Civil Surgeon, maintain his position (except by direct pecuniary loss) or command the respect necessary to his official position?

With one exception only the Military Assistant Surgeons employed as Civil Surgeons in Bengal, Burmah, the Punjab, the N. W. P. and Central Provinces, range from 40 to 50 years of age and from 20 to 32 years service a very large portion of which has been spent as Executive Medical Officers drawing first class allowances, until the promulgation of the order of 2nd July 1897, which consigning them to second class rates and degrades them beneath the level of their subordinates, P. W. D., over whom they have the precedence of rank, but who under Article 1105, Civil Service Regulations, are entitled to first class travelling allowances while in charge of districts and sub-divisions.

What the want of official respect is "like," and a man should travel as befits his rank or position if he

is always travelling first class. It is not to be said by the class which he is not permitted to draw travelling allowance for, consequently he is not entitled to draw travelling allowance, and it is simply impossible for him to do so. The result actually due to his position or to the Government's action is that official independence of action and action so necessary to District Heads of the Government.

When travelling by usual steamers, there is no proper accommodation for European or European-looking passengers, who must rough it out with the third class passengers who are not remarkable for their cleanliness; so, whether it or not, the Military Assistant Surgeon, Civil Surgeon, must either travel with the coolies, police constables, petty clerks and other low-downs, or pay and travel first class, though only entitled to accommodation at second class fare. The hardship is more apparent and the loss understood when it is explained that first class fare is nearly four times that of the second and eight of the third class.

A District Medical Officer authorized to give evidence in sub-divisional or town law-courts, perhaps 25 to 50 miles or more distant from his head-quarters, is entitled to first class expenses if he be a member of the Unconvenanted or Unconvenanted Indian Medical Service; but should he happen to be a Military Assistant Surgeon, he cannot claim more than the expenses allowed to a second class witness.

The nature of his duties demands frequent inspection tours; but as he must not remain away for long from head-quarters where he may be wanted at any moment, he must get over the distance between stations as quickly as possible. No such privilege for him as is extended to some of the public services, of 12 miles being sufficient for a day's march or being allowed three days to cover distances of 40 miles, which to him must mean one day's travel. The more rapid the progression the greater the costs of transit and the more heavy the loads at his girth, to which his family have also a rightful claim. To this add the necessity for maintaining extra and higher-paid servants for tour service, and it will be seen how grievously weighty the infliction of having to continually pay first class travelling expenses when allowed recompense (rather part compensation) at second class rates.

In Burma, where the cost of living is 30 to 50 per cent. higher than in any part of India, the distress and humiliation caused by this reduction in the rates of travelling allowance is most keenly felt, as Burma is gradually a new annexation in which the progressive material civilization of the country entails a very severe tax on the purse and energy of the Civil Surgeon, who does not get the Burmah allowance of Rs. 150 granted monthly to officers of the Forest, Survey, Telegraph, Postal and Public Works Departments, though unlike them he has to constantly be on the move verifying vaccination reports, controlling dispensaries, inspecting the dispensaries and sanitary arrangements of the numerous towns and villages in his district, visiting the Civil Police Stations, being on various committees of investigation, attending the various subordinate courts

to give medical relief, including for Police Battalions and medical care of officers taken in in various distant sub-divisions and townships, besides being given medical charge of Military Police Battalions, for which extra duty he does not draw any extra allowance, although he has to periodically visit the many outposts in which these battalions are split up, and is responsible for the hospitals belonging to the several outposts.

I cannot understand why such an unjust order was ever promulgated, but I think if we laid our case before His Excellency the Viceroy for consideration, he would certainly rescind an order that curtailed our travelling allowances, and by so doing not only puts us to considerable and unendured privations and hardships, but also makes up a cynosure in the eyes of those from whom we have the right to command respect.

Yours &c., SPTRO MELIORA.

—:o:—

GRIEVANCES OF MILITARY HOSPITAL ASSISTANTS: A REMEDY.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—In the Field Service Manual, India, it is laid down that Eurasians, other Christians and Jews belonging to the Commissariat, Political, Telegraph, &c., when on field service, are entitled to draw European rations and to the scale of field kit allowed to Europeans. As the regulations now stand, Eurasians and Jews of the Hospital Assistant class are only allowed free native rations and the field kit authorized for natives. Perhaps it is not generally known that there are a few Eurasians and Jews in the department. I hope that this omission has only to be pointed out to be remedied.

2. When a Hospital Assistant is on the line of march from one station to another, he is not entitled to compensation for quarters, having to sleep in the office tent, neither is his family housed free or granted compensation, so he has to provide accommodation for them out of his own slender means.

3. Agreeably to A. R. I. Volume X, Hospital Assistants travelling on sick leave are only entitled to free passage by rail and steamer. It sometimes happens that Hospital Assistants on sick leave have to travel inland where there is no rail and the cost of conveyance has to be disbursed from their own pockets. This lately happened in connection with the Tooli Field Force, where Hospital Assistants sent on sick leave had to pay for their conveyance from Bannu to Kushalgarh—a distance of 110 miles. A single seat in a tonga costs Rs. 14 which is the cheapest rate available, and fancy a Hospital Assistant on Rs. 25 having to pay this amount from his own purse. There was no other alternative. In connection with this I have also to point out that Hospital Assistants, however ill or disabled, are not entitled by regulations to a sick attendant from their regiments, neither is a servant allowed a free passage when accompanying them.

4. A. R. I. Volume X rules that Hospital Assistants travelling on duty by land are allowed mileage rates at 2 annas a mile if the distance covered exceeds 20 miles a day. In some localities where conveyance is dear, this mileage rate barely suffices to meet half the expenses incurred. There is no provision made for special rates of mileage for certain localities such as is conceded to Civil Hospital

Assistants by Civil Service Regulations, neither are actual expenses admissible under existing Army Regulations.

5. The wife of an Eurasian drum-major, fardar major, trumpeter major, &c., is entitled to Rs. 3-6 a month as European subsistence allowance and Rs. 2-8 to support child, vide para. 363, A. R. I., Vol. I., Part II. As this boon is conceded in point of nationality, Eurasian Hospital Assistants have also a just claim, being part of the native army, but under the regulations in force they are not included.

6. Cots, pillows and mattresses are sanctioned for hospitals of native troops in the proportion of 5 per cent. on the strength of the regiment. Owing to the frequent transfers of Hospital Assistants and the restricted scale of 2 maunds of baggage when travelling, it is impossible to carry any furniture. If the following suggestions are approved by Government, it would cost nothing extra to the State:—

For a married man.

2 Iron cots		
2 Pillows stuffed with coir	...	
2 Mattresses do. do.	...	
*1 Camp table	...	From the authorized complement
*1 Camp chair	...	allowed to Regimental Hospitals,
* Authorized for route march,	...	vide Appendixes
vide Appendix 13, A. R. I. Vol. VI...		12 and 13, A. R. I.,
For a single man		Volume VI.
1 Cot iron	...	
1 Pillow stuffed	...	
1 Mattress stuffed...	...	

There are only 2 Hospital Assistants attached for duty to each regimental hospital. The average strength of a regiment is 840, thus allowing 42 cots, mattresses, &c. for each hospital.

Yours &c., AN EURASIAN HOSPITAL ASSISTANT

—:o:—

IN THE WRONG BOX!

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Your journal of the 1st March contained a letter from "Onlooker" about which I should like to say a few words, if you will allow me. I don't know with what view the names of a few men holding British diplomas were published, to which "Onlooker" takes exception, unless it was to bring to notice that the men in question were a credit and renown to the service to which they belong.

To come to the point, the I. S. M. D. is first and foremost a Military Service, and the Military Assistant Surgeons forming it, are, I take it, properly qualified for the work they have to do. If the diplomated man therefore has to work with or under his seniors when the exigencies of the service require it, why then! it is quite in the fitness of things that he should do so, and there is nothing more to say about it.

It is fatuous to enquire, "if a Surgeon-Lieutenant A.M.S., or I. M. S., would serve under a Surgeon-Major I. S. M. D.?" The services are quite distinct, and the nature of duties different; further, it is never intended that these superior officers should ever come to serve under commissioned officers of the local service.

On the other hand, the diplomated Assistant Surgeon takes his position with his non-diplomated fellows on a com-

and the military department and the civil department. I don't see that we are called upon to appoint a man just because he is the holder of a diploma. If he comes amongst us, we know him as a man, which he undoubtedly is. I don't see that the State benefits by having degree or diploma holders in the subordinate ranks. The duties, both civil and military, that fall to our share are I believe, just as efficiently discharged by men who have not got diplomas from the United Kingdom.

It is popularly believed, both in and out of the service, that Military Assistant Surgeons (the pure unadulterated article as turned out from Calcutta) are badly-paid, badly-housed, and in a word badly treated. This then being the case, I think it is foolish on the face of it to add to your value by obtaining diplomas and degrees, when it is understood that your employer does not require, and what is more, is not prepared to pay for a superior article. I further think that it is against the sacred tradition surrounding the profession of medicine, for highly trained and expert medical gentlemen holding classical degrees from the great Universities of England, Ireland and Scotland, to lend themselves to the performance of derogatory work such as compounding of drugs and walking round with hand-books. But here the service is not at fault nor are its administrators, but the degree holders themselves.

Is a remedy sought for this state of things? I should say, these highly qualified gentlemen should leave the service, should have left it long ago in fact, and taken up more congenial work and placed themselves beyond the risk of ever being called upon to perform undesirable duties in connection with military hospitals.

Yours &c., NEMO

THE WAR RESERVE OF MILITARY ASSISTANT SURGEONS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—On perusing this article in the *Record* of the 15th February, I was pleased to see that a fair number of Railway appointments have been reserved by Government with a view of extending the services of Military Assistant Surgeons in the civil department.

This scheme gives thirty appointments, good, bad and indifferent, but yet welcomed, which, I would beg to suggest, be equally divided among the three provinces.

Bengal and Madras at present hold out a very large number of civil appointments to their Military Assistant Surgeons, and could well afford to give their brothers in distress on the Western side half the Railway appointments.

Further, the Director General could be approached with a view to move Government to give back to the Military Assistant Surgeons of the Bombay establishment, such appointments as were held by them some years back, and from which a number of Military Assistant Surgeons were only removed owing to the emergency of the service. Surgeon-Major-General BAINBRIDGE, I feel sure, would acquiesce and ably support this movement.

The Military Assistant Surgeons would form a most substantial war reserve and capable of efficient service in times like the present, when war, pestilence, famine and internal disturbances run riot. Would the present civil Assistant Surgeons and Hospital Assistants be of much service in a war on an extensive scale?

The appointments I allude to are *Wazirpur, Sadra, Larkhane, Tata, Panahgani, the Deonar and Kaldi gangs*. There is one Civil Surgeoncy, viz., *Shalapur*, and I believe this will, on the retirement of the present incumbent, go to a Civil Assistant Surgeon, and for which, I hear we are to get some outlandish dispensary (thank!). I would here also suggest the employment of Military Assistant Surgeons in the various large hospitals and districts as Assistants to the Civil Surgeons, viz., *Ahmednagar, Ahmedabad, Belgaum, Hyderabad, Indore, Kurrachee, Rajkote* and an additional *Sub class Assistant Surgeon*, after his completing three years' military duty in the *Jamsetjee Jeejeebhoy and the St. George Hospitals (Bombay)*.

Yours &c., ONE OF THE EIGHTEENTH CENTURY.

BYOULLA, 21st March 1898.

THE DELHI POISONING CASE.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I have read with much regret the decision of His Honor the Lieutenant-Governor in the Delhi poisoning case, in which the life of a valuable Government servant has been lost simply through the neglect of the Civil Surgeon and the compounder who dispensed the prescription. In my opinion the Hospital Assistant has been treated most unjustly. I do not conceive in what way he is to blame, when he was not present at the time that the prescription was dispensed.

The compounder ought not to have dispensed the prescription. He should have waited for the Hospital Assistant. Further he had no business to alter the prescription. He should have returned it to the Civil Surgeon for correction. The poor Hospital Assistant has been punished most severely for the fault of others.

It is all very well to say that the rules regarding the custody and dispensing of the poisons have been neglected, and it might be so to some extent in this case. But what is to be done in dispensaries where there is only one medical officer. Is he to attend his out-door patients, who number sometimes two or three hundred, or make up the prescriptions for them? How is it possible that the medical officer should attend patients and dispense medicines at one and the same time.

During the last three years three such mistakes have occurred with fatal results. It is a great pity that instead of appointing two medical officers to a dispensary, the Government is punishing the poor medical officers for no fault of theirs. Every big dispensary ought to have a medical officer with a Hospital Assistant under him. And then if a prescription is dispensed wrongly, the actual man should suffer, not the man who is not present at all.

Yours &c., ASSISTANT SURGEON.

DYSMENORRHOEA AND ITS TREATMENT.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Permit me to express sincere thanks for suggesting a light silver intrauterine stem for the cure of dysmenorrhoea dependent on uterine stenosis. Will you please further oblige me and my poor patients by a more explicit description of this cure.

On referring to the latest edition of ARNOLD'S surgical instrument catalogue, one is simply bewildered at the number of stem pessaries advertised, while there is no chance of knowing the merits and demerits of each. The silver stem not being among the number, I would request you to please let me know under what trade-name it is obtainable.

1. Is it a solid stem or a hollow one?
2. Is it to be worn continuously, even during the courses?
3. Is it to be removed for the purpose of cleaning or not?
4. Is it to be removed if it causes pain, especially during the courses?
5. While it is worn, is it advisable to use a daily vaginal wash?

6. In the case of virginity with anteversion, the sound cannot be introduced, how am I to manage the introduction of the stem?

Trusting to be excused and deeply thanking you on behalf of my patients no less than on my own behalf.

Yours &c., B. G. ALPA.

(The silver stem referred to is obtainable from Messrs Barker Bros. of Calcutta, who so advantageously advertise in this Journal. The stem is a solid one. It is worn continuously. If by its presence the menstrual flow becomes too copious or is too protracted, the stem is removed till the flow stops and it is then inserted again. It is well to remove the stem once a month for a fortnight, to cleanse it, and then reinsert it. The stem is efficient against pain during the first 24 or 48 hours of its insertion, after that the pain subsides and never returns. If the pain on insertion be severe, the stem should be removed for a day or two and sedatives given. The vagina should be douches daily with a warm saline solution (a mixture of ordinary table salt to a quart of warm water). The stem should not be used in the case of virginity unless the symptoms are distressingly painful and are unrelieved by local and internal sedatives and other anti-spasmodic remedies. In extreme cases of this sort chloroform should be used to adjust the stem.—ED., I. M. R.)

MEDICAL BOARDS AND THEIR FOIBLES.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—The following from *Truth* are facts as true of India as of England:—

"Here is another example of straining at gnats in army medical examinations. A young militia officer, a highly promising man in every respect, was recently rejected on account of an insignificant deformity, due to his having been accidentally shot in one foot. The accident was no impediment to his marching or his gait, or to his performance of any of his duties, as proved by the fact that he had been for some months attached to a line regiment at Aldershot. It was simply a question of appearance but that was enough to settle the case with the Medical Board.

We shall hear next that some man has been rejected on account of an unduly conspicuous pimple on the nose."

"Of course it is true enough, as an Army Surgeon points out in a letter just received, that if the medical examiners pass doubtful men they are not doing their duty to the service or to the taxpayers. But the answer to that is that they frequently do pass doubtful men. While they are straining at gnats they are continually swallowing camels. The camels are simply the candidates who have influence at the War Office. I have particulars of two cases before me now, together with the opinion of an Army Medical Officer that neither man ever ought to have been passed. One of the two has been continually absent from duty since he joined, and has been home from a Mediterranean Station and back, at the public expense, to undergo an operation. This man was let into the army entirely through private influence. Medical Boards are habitually unfair under pressure, and they frequently make glaring mistakes even when they have a free hand."

Yours &c., Surgeon-Lieutenant-Colonel.

CLINICAL INQUIRIES.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Will you or any of the readers of the *Record* kindly inform me through its medium, to what diseases the following symptoms apply, their causes and treatment, both medicinal and dietetic?

Diarrhoea, 1, 2, 3 or 4 pale liquid motions during the day, griping pains in the abdomen, nausea and retching, vomiting early in the morning and sometimes in the evening, salivation, furred tongue, poor appetite, paleness of the face, dark rings round the eyes, headache and giddiness, noise in the ear, scanty menses (sometimes attended with pain), disinclination for work, both physical and mental, hypertrophy of the uvula causing a dry cough.

The symptoms have been troubling for the last two years and a half, and have resisted all treatment.

Also if you will kindly inform me whether an operation for fistula in a patient suffering from chronic congestion of the liver is admissible.

In the *Indian Medical Record* of 1st January last, page 30, under the heading "Common Diseases of the Rectum," FOSTER in the *Journal of Medical Science* says that operation for fistula in ano should not be performed when a patient is suffering from hepatic affection; if so, what other treatment for fistula in ano and chronic congestion of the liver is indicated, when Taraxacum, Acid Nitro Hyd. Dil, Podophyllin, Ammon. Chlorid, etc., have all failed?

Yours &c., AN INQUIRER.

MEDICAL ADVERTISING IN CALCUTTA.

TO THE EDITOR, "INDIAN MEDICAL RECORD"

SIR,—All right-thinking men will commend the generosity which prompted your keeping out the names of certain advertising medicine when the complaint about them was first sent to your journal. You did rightly however in giving them all due publicity when the complaint was made a second time. The measure you adopted has had the salutary effect, I am glad to say, of putting a stop to the advertisement altogether, for it now ceases to appear in the *Statesman*.

The following is a cutting from the *Statesman* of the 24th March, and as it is constantly appearing, perhaps you will oblige by giving the advertiser a little more professional prominence:—

Dr. S. B. MITRA, B.S., M.B. London, has removed to 36, Wellington Street, Calcutta.

Hours of Consultation at his residence:—

From 7 to 8 A.M. (free).

From 4 to 5-30 P.M. (charged).

Yours &c., L. R. C. P. & S. Edin.

THE LEGITIMATE PREVENTION OF CONCEPTION.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Under the above heading in your issue of 16th March last, your correspondent "Anti-Malthus" speaks of a check pessary as effectually preventing conception. Will you or your correspondent kindly inform me as to the following points:—

(1). What sort of an article it is, whether it perfectly covers the os uteri, and whether it is liable to displacement during intercourse?

(2). How long can one pessary be used ordinarily?

(3). Where they can be procured and the price of a sample?

Yours &c., M. B.

BARINGS.

Book Reviews & Medical Trade Notices.

OUTLINES OF RURAL HYGIENE.

By HARVEY B. BASFORD, M.D.

Inspector for the State Board of Health of Pennsylvania.
(Publishers: The F. A. Davis Co., 1914-16 Cherry St., Philadelphia. Extra cloth, 75 cents net.)

This handy little volume of 84 pages will be found a convenient and helpful guide in relation to those simple yet important questions that concern village hygiene in India. Though written for America, it is remarkable how appropriate the hints given in this work are for a tropical climate.

SPINAL CURVES.

By NOBLE SMITH, F.R.C.S.

Surgeon to the City Orthopaedic Hospital, London.

(Publishers: Messrs. SMITH, ELDER, & Co., London. Price 5s.)

This book of 153 pages contains a complete and thoroughly practical résumé of the interesting subject of spinal curves. It is excellently illustrated.

ANATOMY, PATHOLOGY AND SURGERY OF INTUSSUSCEPTION.

By D'ARCY POWER, M.A., M.B., F.R.C.S.

Hunterian Professor of Pathology and Surgery at the Royal College of Surgeons of England.

(Publishers: The REBMAN Publishing Co., London. Price 10s. 4d.)

A VERY good book by a very good surgeon.

THE "VOLUNTEER."

We are glad to notice the energy and enterprise shown by *The Volunteer*. This journal was only started in February, and yet issued a supplement on the 29th ultimo, announcing the amalgamation of the Infantry Volunteer Corps in Calcutta, while the daily papers, with one exception, did not make the announcement till the 30th. Every volunteer in India should subscribe to the journal.

THE INDIAN RAILWAY SERVANTS' MANUAL.

ALTHOUGH we are not in the habit of reviewing books outside our profession, we make an exception of the "Manual" recently compiled by Mr. JOHN R. HARDING, of the Bengal Central Railway Company, Ltd., a prominent Anglo-Indian. The book is excellently got up, the contents are arranged in alphabetical order, and while fulness of information is aimed at, brevity has not been lost sight of. It should prove of immense benefit not only to railway servants, but to magistrates, lawyers etc., having to deal with railway cases.

SCOTT'S EMULSION.

SCOTT AND BOWNE, LTD., 95, GREAT SAFFRON-HILL, E.C.

The value of the hypophosphites combined with cod-liver oil, especially in wasting diseases and in debilitated conditions, is well known. In addition to these constituents the above preparation contains also glycerine, which is well recognised as assisting very materially in the absorption of oils and fats. We have examined the preparation with care, and find that it fulfils all the requirements and presents all the conditions of a very satisfactory emulsion. In appearance and consistence it is not unlike cream, and under the microscope the fat globules are seen to be of perfectly regular size and uniformly distributed. In fact, the preparation microscopically examined presents the appearance of cream. So well has the oil been emulsified that even when shaken with water the fat is slow to separate, the liquid then looking like milk. The taste is decidedly unobjectionable and is pleasantly aromatic and saline. We had no difficulty in recognising the presence of the hypophosphites in an

unimpaired state. The emulsion keeps well even when exposed to wide changes of temperature. Under the circumstances just described, the emulsion should prove an excellent food as well as a tonic.

A NEW ASEPTIC CABINET.

Messrs. ARNOLD AND SONS, of West Smithfield, inform us that they have constructed a cabinet for the storing of surgical appliances at a price that will place it within the reach of every general practitioner. It is made of iron, enamelled white, with 2-in. polished plate glass top, back, sides, and door, with two plate glass shelves with polished edges and is manufactured in two sizes—18 x 15 x 8 in., 35s; and 24 x 18 x 11 in., 55s. The cabinet should prove useful to many institutions and practitioners.

Government Medical Gazettes.

GOVERNMENT OF INDIA.

Asst Surgn. Alexander Gates, I. S. M. Dept., has been transferred to the pension cash.

Brig.-Surgn.-Lieut.-Col. Alexander Crombie, M.D., I. M. S. Bengal, Surgn.-Supdt. Presy. Genl. Hosp. Calcutta, is permitted to retire from the service from the 7th April 1896.

The services of Surgn.-Capt. B. H. Deane, I. M. S., Surgn.-Capt. B. C. Oldham, I. M. S., and Surgn.-Capt. R. Bird, M.D., M.S., F.R.C.S., I. M. S., are placed permanently at the disposal of the Govt. of Bengal.

The services of Surgn.-Capt. U. Milne, I. M. S., are placed temporarily at the disposal of the Govt. of N.-W. P. and Oudh.

The services of Surgn.-Maj. J. M. Cadell, M.B., I. M. S., Bengal, are replaced at the disposal of the Govt. of N. W.-P. and Oudh, from 4th Dec 1897.

Surgn.-Lieut.-Col. C. J. H. Warlen, I. M. S., Bengal, Medical Store-keeper to Govt., Bengal Comd., is placed on special duty under the Govt. of India, Home Dept.

The services of Surgn.-Col. J. H. Newman, M.D., I. M. S., Bengal, Insp. Genl. Civil Hosp., Bengal, are replaced at the disposal of the Milly. Dept.

The services of Brig.-Surgn.-Lieut.-Col. C. Little, M.D., I. M. S., Madras, San'y Comr. Hyderabad Assigned Districts, are replaced temporarily at the disposal of the Milly. Dept.

Brig.-Surgn.-Lieut.-Col. J. O'Brien, M.D., C.M., I. S. M., Bengal, Prof. of Surgery, Med Coll., Calcutta, is granted furlough for seven months.

Surgn.-Lieut.-Col. R. D. Murray, M.B., I. M. S., Bengal, Civil Surgn., Howrah, to officiate as Prof. of Surgery, Med. Coll., Calcutta, during the absence of Brig.-Surgn.-Lieut.-Col. J. O'Brien, M.D., C.M.

BENGAL GOVERNMENT.

Surgn.-Lieut.-Col. Gordon Price, M.D., Bengal Estab. retired from the service, 16th Jan'y 1896.

Asst. Surgn. Sarat Chandra Sur to do sup'y. duty, Med. Coll. Hosp., Calcutta, from 16th Feby. 1896.

Asst. Surgn. Dinno Nath Mitter, Demonstrator of Anatomy, Campbell Med. School, is apptd. Teacher of Anatomy in that Institution.

Asst. Surgn. Kali Nath Banerjee, Katihar Ry. Hosp., E. B. S. Ry., leave for one month.

Asst. Surgn. Nilkanto Chatterjee to have temp. med. charge Katihar Ry. Hosp., E. B. S. Ry.

The following Civil Hosp. Assts passed the medico-legal examination of Medical Subs. on the 31st Dec 1897 in the following order:—

Mon Mohun Mukerjee, Fazlur Rahim, Ramendra Banerjee, Jogendra Nath Ghose, Fariduddin, Shoshi Bhushan Bagchee

Asst. Surgn. Narendra Nath Gupta to temp. med. charge Madhubani sub-div. and dispy., Darbhanga dist.

Asst. Surgn. Mathura Nath Sen, Madhubani sub-div. and dispy., leave for three months.

Asst. Surgn. Purno Chunder Das Gupta, furlough for six months.

Surgn.-Maj. A. R. W. Sedgewick has been granted an extension of furlough for six months.

Wm. M. M. Traill Christie, M.D., to be an Insp. Med. Officer at Chausa Station, E. I. Ry.

Miss Durham to the Malwa Observation Camp, B. and N. W. Ry.

PUNJAB GOVERNMENT.

Hosp. Asst. Lachman Das, Lahore Central Jail Hosp., three months' privilege leave, 3rd Feby. 1898.

Hosp. Asst. Kahn Singh die real duty at Lahore Central Jail Hosp., from 31st Jany. to 3rd Feby. 1898.

Hosp. Asst. Mirza Imdad Beg, Police Hosp. Rawalpindi, to the Nurpur Fair held in that dist., from 30th Feby. to 14th March 1898.

Hosp. Asst. Wazir Chand, Chamba Dist., 4th div., privilege leave for one month, from 5th Feby. to 4th March 1898.

Hosp. Asst. Bishamber Nath, Police and Civil Station Hosp. Delhi, is appointed to the 3rd class for two years, from 25th Jany. 1898.

Hosp. Asst. Saranath resumed charge of his duties on the Toot Independent Executive charge div., from 12th March 1898.

Hosp. Asst. Hameed Muhammad Khan, was placed on genl. duty, at the Mayo Hosp., Lahore, 30th Feby. 1898.

Hosp. Asst. T. Franklin, to the Dist. Jail Hosp., Vadrabad, from 1st March 1898.

The four months' leave granted to Hosp. Asst. Ghulam Nabi is extended by a further period of two months.

Hosp. Asst. Wajid Ali Shah, Farjib Pwar, Erab., is permitted to resign the service, from 5th March 1898.

CENTRAL PROVINCE GOVERNMENT.

Hosp. Asst. Narayan Yamarak, Bhopal Poor-house, to do duty under Civil Surgn., of Bhopal.

Hosp. Asst. Abdul A. Shah, Mandla Branch Disp., Nimar dist., is reduced to the grade of passed med. pupil for one year, from 5th Feby. 1898.

Hosp. Asst. Ramkrishna Lal to do plague duty Nagpur City, from 26th Jany. 1898.

Hosp. Asst. Kabil Ahmed, Bagaranj Poor-house, Nagpur, to do plague duty, 5th Feby. 1898.

Hosp. Asst. Majid Salar, Police Hosp., Chanda, Sironcha Branch Disp., Chanda dist.

Hosp. Asst. Kuppurajdeo Naidu, Sironcha Branch Disp., Chanda dist., to the Police Hosp., Chanda.

Hosp. Asst. Baghunath Tukaram, Main Disp., Chanda, held charge Police Hosp., from 29th Jany. to 18th Feby. 1898.

N.W.P. AND OUDH GOVERNMENT.

Hosp. Asst. Karim Bakhsh, from reserve duty, Benares, to Lalitpur Disp., Jhansi.

Hosp. Asst. Jawant Ray, Sikandrabad Disp., from 22nd Nov. 1897.

Surgn.-Maj J. J. Pratt, Civil Surgn., from Frazabad to Agra.

Surgn.-Maj W. G. F. Alpin, Civil surgn., from Mirzapur to Fyzabad.

Surgn.-Maj. C. C. Yald, Civil Surgn., from Hardoi to Mirzapur.

Asst. Surgn. E. Dene-Brosses, plague insp., Cawnpore, to plague duty at Hardwar.

Asst. Surgn. E. Dene-Brosses, on plague duty, from Hardwar to Ghazabad.

Surgn.-Capt. A. Milne, to plague duty, Saharanpur dist.

Surgn.-Maj J. J. Pratt, Civil surgn., Agra, to hold visiting med. charge of the Etawah dist.

BURMA GOVERNMENT.

Hosp. Asst. Khugwan Prasad assumed charge Reformatory School, Mandalay, 8th Dec. 1897.

Hosp. Asst. Ram Nath Pal assumed charge Police Hosp., Moulmein, 1st March 1898.

Hosp. Asst. H.-J. Chaudier Barua to Thongwa dist., 26th Feby 1898.

Hosp. Asst. Bala Narain Chopra, leave for two months in extension.

Hosp. Asst. Kuntl Bawman Nair assumed charge Police Hosp., Pinya (Monyung) 23rd Feby. 1898.

Hosp. Asst. Haroo Charan Das is entitled to the pay of the next higher grade from 26th Nov. 1898.

Hosp. Asst. Nawab Khan assumed charge Outpost Hosp., Kyaukseleu, 19th Dec 1897.

Hosp. Asst. Nawab Khan assumed charge Outpost Hosp., Shwemawngin, Ruby Mines dist., 12th Jany. 1898.

Hosp. Asst. Raj Chander Bagua assumed charge Civil Disp., Kwaikiet, Thongwa dist., 1st March 1898.

Hosp. Asst. Neeb Abdul Khader resumed charge Civil Hosp., Thawawaddy, 26th Feby. 1898.

Hosp. Asst. Neeb Abdul Khader resumed charge look-up, Thawawaddy, 26th Feby 1898.

Hosp. Asst. Abdul Kureim to Pakokku dist., 26th Feby. 1898.

Surgn.-Maj J. E. Mallins, to be Senior Surgn.

Surgn.-Capt. E. M. Worsfold, to be Senior Surgn.

Hosp. Asst. Shih Chuan Shih, to be Senior Hosp. Asst., from 3rd Sept. 1897.

Hosp. Asst. Muhammad Abdul Jabbar, to be Senior Hosp. Asst., from 3rd Sept.

Hosp. Asst. Faiz Ahmed, to be Senior Hosp. Asst., from 17th Oct 1897.

ASSAM GOVERNMENT.

Hosp. Asst. Jasmit Kant Dhuip, Kalraha Mdy. Police-outpost, North Lushai Hills, to Newgong dist., to Shing Dhuip, from 20th Feby. 1898.

Surgn.-Capt. E. S. Peck, Offg. Med. Officer, Loh Wing, 17th B. I. Dibragarh, to hold charge Lakhimpur dist., from 12th Feby. 1898.

Hosp. Asst. Himat Deen, Tura, Charitable Disp., to the Khasi and Jaintia Hills dist., to Jewai sub-divn., from 4th March 1898.

Leave for three months is granted to Hosp. Asst. Nair Ali, North Lushai Hills, from 5th March 1898.

Hosp. Asst. Anukul Chandra Das Gupta, Sylhet dist., to Jagannathpur Disp., from 5th March 1898.

Leave for two months is granted to Hosp. Asst. Jahan Chandra Datta, Sunamganj Disp., and Look-up from 5th March 1898.

Hosp. Asst. Chandra Kisor Sen to Sunamganj Disp., and Look-up, 5th March 1898.

DOMESTIC OCCURRENCES.

The charge for inserting a Domestic Occurrence is Rs. 1 for subscribers and Rs. 2 for non-subscribers, which should be forwarded in stamps with the announcement.

BIRTHS.

MCNAUGHT.—On the 4th March, at Quetta, the wife of Surgn.-Capt. J. G. McNaught, M.D., A.M.S., of twins—son and daughter.

MAIDMENT.—On 8th March, at St. Thomas's Mount, the wife of Surgn.-Capt. F. G. Maidment, 14th M.I., of a daughter.

HUDSON.—On 16th March, at Mannaroddi, Tanjore District, the wife of Henry Hudson, M.A.S., of a daughter.

DIMMOCK.—On 19th March, at St. Vincent's, Malabar Hill, the wife of Surgn.-Maj. H. Peers Dimmock, I.M.S., of a son.

MARRIAGES.

SEAL—WARR.—On 12th March, at St. Paul's Cathedral, Calcutta, Charles Edward Baldwin Seal, M.B.A., D.S.O.F., to Jessie, second daughter of W. Warr, Tetbury, Gloucestershire.

DEARE—CROSTON.—On the 15th March 1898, at Christ Church, Ipswich, by the Rev H. Deare, Chaplain, Surgn.-Capt. B. H. Deare, I. M. S., to Ellen Lancaster Croston.

DEATH.

EVANS.—On 21st Feb. at Fairbairn, Telford, Hampshire, late of Bath, William Evans, M.D., F.R.C.S., late Madras Medical service, aged 69 years.

NOTICES TO CORRESPONDENTS.

T. D. 7. (Kampre).—You will find all the information you need regarding Indian and British diplomas in the new edition of the "Medical Register and Directory of the Indian Empire."

H. S. (Jalilpur).—Attendance at Indian Medical Colleges is fully acknowledged at the British Schools if properly attested.

E. D. (Gugranwalla).—A military medical officer, who has passed the Entrance Examination, may at any time resign his cadetship and claim certification for his lectures and other attendance on payment for same.

ORIGINAL ARTICLES.

PERSONAL REMINISCENCES OF SYME.

By **DR. ROBERT FURL, DENTON MORGAN, M.D., LL.D.,**

Ex-President, American Medical Association.

In the winter of 1853 the writer, a very young medical student, began to attend the clinical teachings in the Royal Infirmary of Edinburgh. In the history of that institution and of the medical school connected therewith, it is freely admitted that there never had been a time when the fame of the faculty stood higher than it did then. SYME, SIMPSON, BENNETT, CHRISTISON, GAIRDNER, BARNES and others constituted a teaching faculty rarely if ever equalled by any medical school. It was under those inspiring conditions that the writer first had the honor of becoming acquainted with Professor SYME, whose fame as a practical surgeon and teacher has been enlarged, certainly not diminished, by the lapse of time. It is not the purpose of this paper to review SYME's professional career, but rather to record, for the entertainment of those who may feel an interest therein, a few personal reminiscences illustrative of his personal character and the relations which existed between the great surgeon and his humble pupil, the writer of this article.

At an early stage of my medical studies the plain matter-of-fact method of clinical teaching characteristic of Professor SYME impressed me so deeply that it became the object of my ambition to become associated with him in his work in the wards of the Royal Infirmary. In a medical school which numbered many hundreds of students from all parts of the world, many of them sons, friends, or pupils of former students of Professor SYME, it can be readily understood that it was no easy matter for a youth whose early years had been to a large extent spent, as mine had been, in the backwoods of Canada, and who was devoid of any special association of a professional nature with Edinburgh people, to obtain favorable consideration for appointment of any kind in the Royal Infirmary. Perseverance and determination, however, over-

came many difficulties, and in the end, after several disappointments, I succeeded in getting my object. It so happened that in the summer of 1859 a fellow student, who had the privilege of a position on Professor SYME's staff, desiring to avail himself of a few weeks' holiday, suggested the feasibility of my filling temporarily the position which he occupied. Consequently once again, a request was made to the Professor that the writer should be accorded the privilege of taking the position held by his friend during the latter's absence. On this occasion I had the advantage of the cordial support of the Professor's house surgeon, Dr. JOSEPH BALL, to whom I have always felt sincerely grateful for innumerable acts of kindness during my student days and since. With characteristic brevity and decisiveness, the Professor quietly remarked in response to my petition, "Very well, sir." The next day found the writer in line with the other members of the Professor's staff, joyfully assisting in the regular work of the Royal Infirmary. This work consisted of the examination of *new*, the dressing and treatment of old, patients, and assisting at the performance of operations in the amphitheater, etc. Before many days had passed in this work, a case occurred which elicited from Professor SYME a direct test question to his staff, as follows: A man had received a blow on the head, cutting through the scalp and laying bare the bones of the skull to a slight extent. After some days this patient developed alarming symptoms, namely, rapid pulse, severe headache, vomiting, delirium, etc. (The clinical thermometer had not then been invented.) Having looked him over, the Professor said to those about him: "What do you think is the matter with this man?" After a few moments of silence on the part of all present, the writer ventured the opinion that it was a dural maternal abscess, and the Professor very pleasantly replied, "Quite right, sir." The next question was: "What do you think the result will be?" to which the reply was made, "Death." The Professor expressed his approval of the diagnosis and prognosis, and ulterior facts fully vindicated both. This incident, simple as it was, has always been a very pleasant memory to me.

The limit of my appointment on the staff was three months, and the time soon passed away. With feelings of intense regret and anxiety the flight of time was noted, and the sad fact appreciated that my association with work so congenial was soon to cease. As the time approached, however, I was in one way or another made bold enough to hope that an exception might be made in my case and an arrangement arrived at by which I might continue on the staff during the ensuing winter session of six months. With a feeling of considerable trepidation I ventured one morning to invade the sanctity of Professor SYME's private professional headquarters, at No. 2 Rutland Street, where I made known to him my ambition to continue in the service as a member of his staff for six months longer. His reply was: "I will be most happy, sir; you have been very active and useful to us." I doubt whether any soldier seeing his name honorably mentioned in special despatches ever felt greater pride and satisfaction than I did when I heard those few simple words, coming as they did from a man who never condescended

in history or biography of any kind, a man who was universally known as "a man of few words" and one whose every word was understood as saying exactly what he meant and meaning exactly what he said. Within a few days after this interview I found myself occupying a very responsible and important position of the Professor's staff, a position which I succeeded in retaining for a period of eighteen successive months; during which time it so happened that many of the greatest and most famous of all SYME's achievements as an operating surgeon were performed. His staff of assistants met with him every day in his consulting-room at the Royal Infirmary, between the hours of twelve noon and 2 p.m. In our work there many visiting surgeons were delighted to participate, and the Professor was always willing to listen respectfully to the opinions of every one present, even his youngest assistant, whenever the conditions seemed favorable for such an interchange of views. Moreover, it always afforded him pleasure and made his face light up in a most expressive manner when an original or reasonable diagnostic opinion was expressed, even though it might not ultimately prove to be correct. As an illustration of this the following incident is recalled. A patient had a large tumor in the gluteal region, which presented peculiar and puzzling features. All eyes were fixed upon the sufferer and his tumor, as well as on the Professor as he examined it. Suddenly one member of his staff, namely, Mr THOMAS ANNANDALE, who since then has for many years filled with the greatest ability and success the chair then occupied by Professor SYME, placed his hand on the tumor in a peculiarly suggestive manner, and the Professor, looking up at him, said, "What did you expect to find there—pulsation?" Mr. ANNANDALE replied, "I thought I might, sir, and I think I have." The Professor immediately made the same manipulation and with the same result, and to this day I am able to recall with sincere pleasure the expression of exultation which passed over the great surgeon's face when he found that his youthful assistant had made a brilliant diagnosis in a case of especial difficulty and importance. The same method of examination has many times been resorted to by the writer with advantage, and has been taught by him to several generations of students. The case proved to be one of gluteal aneurism, for the relief of which Professor SYME a few weeks afterwards performed one of his greatest and most "historical" surgical feats. It so happened that the writer had the honor of being a humble but active assistant on the memorable occasion.

Surely it will not be considered improper or in bad taste for the humble assistant in recalling these personal reminiscences to place on record here a recent episode associated with this far-famed case. At the meeting of the British Medical Association in Montreal a few weeks ago, the address in surgery was delivered by Mr MITCHELL BANKS, the eminent surgeon of Liverpool. His address made a very profound and favorable impression upon all who heard it, and certainly on no one more so than his old classmate—myself. At the conclusion of his eloquent oration, every word of which was listened to with the greatest pleasure, I ventured to step upon the platform and, holding out my hand, congratulated him upon the eloquence and beauty of his address. At the conclusion

of the address, Mr. BANKS, who was a most agreeable and interesting man, and whose address was so full of interest and value, pressed his hand at meeting me, and said, "I am glad to make a friend at myself; and I am glad to be introduced to the group of members which has gathered around me: 'If I live to be a hundred years old, I can never forget the day when Professor SYME performed his great operation for gluteal aneurism. Among other things I recollect that at his right hand, and actively assisting him, there stood a smooth-faced, fair-complexioned, enthusiastic young man, with a great mass of auburn hair on his head.' The writer quietly bent that identical head down, and said, 'Well, sir, please just look at it now'—all the auburn and most of the hair were gone. Such was the reunion of two of Professor SYME's pupils after a separation of more than thirty-five years.

Professor SYME has always had the reputation of possessing an austere, reserved manner, and in the opinion of those who knew him best, this impression will be pronounced well founded. At the same time it is no less true that he possessed the faculty of making himself very agreeable to all such as had any claim to his kindly recognition. To the venerable nurses, such as Mrs. LAMBERT and Mrs. FORIER, who served in his wards with the utmost fidelity and industry for half a century or thereabouts, nothing could exceed the kindness and gentility of his manner. When either one of these devoted characters happened to be indisposed, he was always ready and willing to give them his kindest and best care. Whenever an opportunity occurred, he was proud to call out and show forth the surgical intuitions and marvellous diagnostic power of these venerable women, who were not "trained nurses," such as we have to day, but were educated in the school of experience to a degree which, so far as my observation goes, made them equal in most respects to the best "trained nurses" I have ever known. For example, a young man, pale and emaciated, appeared in the Professor's waiting-room one day with a fluctuating swelling just above his right ankle. After careful examination by all present, various opinions having been expressed as to the diagnosis, the Professor, looking around to Mrs. LAMBERT, said, "Mrs. LAMBERT, what do you think?" "I think it is a psoas abscess," was her modest but confident response; and so it proved to be, the autopsy a few weeks afterwards fully corroborating her diagnosis. Having made the above warm reference to this venerable nurse, who had grown old in the service, I feel justified in adding a few words more in regard to her. In so doing I feel certain that of all the pupils who studied surgery under Professor SYME during Mrs. LAMBERT's long service, there does not survive one who will not feel gratified by any kindly or appreciative testimony which may be recorded in her honor. Mrs. LAMBERT had her own suite of plain but comfortable rooms in the Royal Infirmary. One feature of her house-keeping, upon which she especially prided herself, was her potato soup, or, as she called it in the Edinburgh vernacular, "tattie soup." When any member of Professor SYME's staff happened to be delayed by his duties beyond the regular lunch hour, Mrs. LAMBERT was ever on the alert with an offer of a plate of this soup,

...the vessel declared that such an arrangement was impossible, and that the poor fellow would have to take his chances of being buried at sea. The doctor, loath to abandon his patient to what he regarded as certain death, proceeded to make further inquiry about him. On ascertaining exactly who the boy was, namely, the son of the kind-hearted old nurse who had so often cheered his own young heart with her prodigious plates of "tattle soup" when he was a struggling student in the Royal Infirmary, the doctor hesitated no longer, but, taking all the responsibility and assuming all expense, had the sailor lad sent to the hospital, where, after many weeks of careful treatment, recovery took place, after which he had him sent comfortably and safely back to his good old mother "Cast thy bread upon the waters for thou shalt find it after many days."

My midsummer vacations were spent for the most part in Edinburgh SYME'S wards, the *post mortem* theater and the University dissecting-room afforded me abundant facilities for the most profitable kinds of study and work. I always enjoyed free access to the dissecting-room through the kindness of the then head demonstrator, now the eminent scientist and first of living anatomists, Sir WILLIAM TURNER. Brief but most enjoyable visits, however, were occasionally made to the ancestral home of my family, on the Isle of Mull, on the west coast. My kind and affectionate host, a very near relative, on the occasion of my first visit when a freshman medical student, dubbed me "The Professor," and, as usually happens with nicknames, mine very soon became the common property of every tenant, every employee, and every guest of the hospitable old place, and to this day when I return, as I have occasionally done in later years, "The Professor" is my universal designation in perpetuation of a good-humored joke perpetrated forty years ago. The fact of my having been for many years entitled to that (*more or less*) honorable appellation has no possible association with the pet name by which I am still remembered by those loyal and kind-hearted old friends. This leads me to record here an anecdote involving my relations with Professor SYME. During one of my visits to the Highlands, after Mr SYME and myself had become fairly well acquainted with each other, one of the foremen on my cousin's estate came to him one morning to inform him that a high-bred Ayrshire bull was ill and evidently suffering great pain. No one had anything to suggest for the poor animal's relief. At last one of the men said, "Don't you think, sir, that we might consult 'The Professor?'" The laird smiled but made no reply. After breakfast, however, he asked me to observe the animal as he walked about in front of the windows of the breakfast-room and give my opinion as to the ailment. The appearance and actions of the unfor-

tunate subject seemed to be quite characteristic, and I expressed the condition being that of a mass of calculus, causing serious obstruction of the urethra; and I was anxious to operate. My cousin, the laird, at once ordered the men to have the patient placed in a suitable posture and held safely. Then with a common scalpel and a pair of ordinary dressing forceps from my pocket case, I had the satisfaction of cutting down and removing the obstruction, which proved to be a rough oxalate of lime calculus, the size of a good large marble. The present professor of clinical surgery in Edinburgh, Dr. THOMAS ANNANDALE, was at the time Professor SYME'S house surgeon, and being a warm friend of mine, I naturally wrote him a full account of my operation. Not only so, but I also sent the specimen to him. It never occurred to me that the affair would go any further, but in this I was mistaken. Without informing me of his action Mr ANNANDALE showed my letter and the specimen to "The Master," and in that way laid the foundation for a somewhat embarrassing surprise for myself and others.

On my reunion with Professor SYME, his staff and visitors, of whom several were distinguished foreigners, the Professor greeted me as I entered the consulting-room with a show of cordiality which surprised all present, and none more so than myself. Then looking round the room and waving his hand in a very solemn manner towards me, in a most-matter-of-fact tone of voice he said, "An eminent lithotomist." He made no further reference to the matter on that occasion, nor did he offer any explanation, at least in my presence. Nevertheless, I heard of the episode from a good many quarters afterwards, more particularly as to the look of astonishment and the depth of the carmine color which overspread the countenance of the "eminent lithotomist." Notwithstanding Professor SYME'S well-known love of humor and thorough geniality of character, such a practical joke, especially at such a time and in such company, was an event of the greatest rarity.

No man could possibly be more temperate and abstemious in his habits than Professor SYME all through his life. Nevertheless he had a distinct feeling of dislike for that class of ostentatious hypocrites known as blatant teetotalers and temperance preachers. I very well remember the case of a boy of not more than twelve years of age who appeared at the *dinner* suffering from a peculiarly loathsome form of disease. The Professor, with an expression of infinite disgust on his face, asked the youthful transgressor the question, "Are you a teetotaler?" to which the unctuous little sycophant replied: "Oh, yes, sir." "I thought so," quietly remarked the Professor, with an expressive twinkle in his eye, and then proceeded to give directions for the management of the case. At his own dinner table, on my declining to be helped to champagne, the Professor, with an air of comical consternation, exclaimed, "Mr MACLEMAN, I hope you are not a teetotaler!" I replied promptly in the negative, and I told the truth.

My first professional fee came in the following manner: During the Christmas holidays one day the Professor said, "Mr. MACLEMAN, what are you going to do this afternoon?" Of course it was quite evident that there was something special in his heart, and I promptly replied,

"Nothing in particular." Then he said, "I proposed to be at New Haven (a suburb of Edinburgh) at three o'clock this afternoon to meet Dr. FILLAT in consultation. Now I cannot very well go, but if you will take my place, you will first of all see an interesting case of disease of the hip-joint in a young boy: in the second place you will see his mother, a charming woman; and in the third place, you will get a very good fee." I need hardly say that the appointment was duly kept. What was required for the patient was carefully done. I made the pleasant acquaintance of his mother, and the no less agreeable acquaintance of the venerable doctor in charge; moreover, I got the fee, with a part of which I purchased the picture, a reproduction of which appears on the first page of this paper. But over and above all that the expression of confidence and kindly feeling implied in this action of the great surgeon acted as a genuine stimulus to my ambition, the effect of which was long lived.

A patient in the Royal Infirmary, for whom it was my duty to perform minor surgical services, presented me one New Year's day with a fine specimen of a Skye terrier pup as an expression of gratitude. Professor SYME happened to come suddenly and unexpectedly upon me one day while sitting on the door-step of the Royal Infirmary after business hours, along with one or two of the old nurses, playing with my pup. In a good-natured, pleasant manner he said, "Mr. MACLEAN, is that your dog?" I had no choice but to plead guilty. He at once assumed an air of mock severity and looking straight at me said, "Then permit me to inform you that there are just three steps to ruin for a young man first, a dog; second, a pipe; and third, a woman." The experience of my life from that day to this have, I must say, failed to fully justify the Professor's oracular utterance. I have rarely seen the day that I have not been the happy possessor of one or more dogs, and surely have had no occasion to blame them for any misfortunes which may have befallen me. As for the pipe, I have never availed myself of its comforting and insidious influences; and so far as the third, and last, "step" is concerned, I have only to declare, as a matter of actual truth and simple justice, that from my cradle to the present time women have ever been my greatest comfort, blessing and inspiration, in spite of an occasional attack of heartache which after all proved to be quite evanescent.

Time and space would fail me to set down in detail the many occasions when striking episodes occurred in the matter of operative experiences in which I was an eyewitness and more or less of an active participant with Professor SYME. The subject is a fascinating and inspiring one and tends to awaken in my mind memories of the most precious nature. I will only venture to quote a single example here. One winter afternoon Professor SYME asked me to accompany him, along with a former house surgeon of the Royal Infirmary, Dr. GOULAY, to the ancient town of Kirkcaldy. The operation was the removal of a tumor situated deeply beneath the articulation of the lower jaw. It was not a small tumor, and it was not well defined, and of course was closely related to structures of critical importance. Before the operation had proceeded very far, or, in other words, "in the middle of it," with very slight promission a terrific thunderstorm

broke over the scene and the sun was almost totally eclipsed. The darkness which ensued was a small and poorly equipped theatre, and the operation became exceedingly embarrassing. The patient, in the Egyptian darkness the situation was very serious; the hemorrhage from the deep and narrow cavity was rapid, and taking all these circumstances into consideration, the occasion was one well calculated to induce embarrassment and anxiety on the part of all present, especially the operator. The calm, deliberate and efficient action of the Professor in this emergency could hardly be done full justice to by any words at my disposal. I can only declare that in the many urgent emergencies which have occurred in my own experience as an operator during the many years that have elapsed from that day to this, the stimulating and tonic effect of the recollections indelibly impressed upon my mind on that occasion have induced the most sincere feelings of gratitude and admiration. Professor SYME was upwards of sixty-four years old at the time this operation was performed.

The present Lord LISTER became, when still a young and comparatively unknown surgeon, the son-in-law of Professor SYME. All the medical students of Edinburgh of my time will remember Mr. JOSEPH LISTER as an active and enthusiastic teacher and student of surgery.

The manner in which he has fulfilled the most sanguine and enthusiastic predictions as to his future is now a matter of universal knowledge. His father-in-law was one of the most confident and enthusiastic prophets of his future greatness. Not long after Mr. LISTER had been elected to the Chair of Surgery in the University of Glasgow, the following episode occurred, which is very pleasantly impressed upon the writer's memory:

Among the many marvellously interesting and striking cases of aneurism which fell to Professor SYME's lot during the time of my association with him—cases which may be safely regarded as constituting the crowning glory of his great career as an operating surgeon—was the following: A shipwrecked sailor, making a desperate leap for his life, had the misfortune to rupture the common iliac artery in the neighbourhood of its bifurcation, giving rise to an enormous pulsating tumor. Emboldened by his recent brilliant successes in the treatment of aneurism, Professor SYME, after careful consideration, decided to make a desperate effort to save, by operation, the life of this unfortunate man. When the time for the operation was near at hand, he wrote to Professor LISTER, informing him of his proposed bold and critical undertaking and inviting him to be present, and as the sailors say, "to stand by." Professor LISTER arrived in Edinburgh the day before the operation and brought with him an instrument which, as a result of his reflections about the case, he had been led to invent—an instrument now familiarly known as LISTER'S aortic compressor. The writer enjoyed the privilege of being present when Professor LISTER presented to his distinguished father-in-law the instrument in question. Professor SYME looked at the instrument and, notwithstanding his great regard for his brilliant and promising son-in-law, the naturally conservative turn of his mind asserted itself and expressions, facial and verbal, of a decidedly skeptical character are

very distinctly marked. The operation took place, and of course was conducted with the utmost coolness and care. Professor SYME laid open the cavity of the enormous aneurism; hemorrhage, such as it has not often been my fortune to witness, was encountered, and the fact is that had it not been for Mr. LISTER's newly devised instrument, by which, as he had hoped and intended, the circulation through the abdominal aorta was perfectly controlled, Professor SYME could not have escaped the great misfortune of losing his patient on the table from hemorrhage. As it turned out, not only was that catastrophe avoided, but the ligation of the common, internal, and external iliac arteries had the effect of saving the patient's life. It has been my privilege to place on record in the medical journals several cases in which by the use of this very instrument the lives of my patients have been saved, which otherwise would have been quite impossible.

An eminent American surgeon, visiting Edinburgh and enjoying the privilege of association with Professor SYME in his hospital work, obtained a photograph of the Professor, and laying it before him, in the presence of some of my classmates and myself, requested the favor of the autograph of the original. Without a moment's hesitation the simple words "JAMES SYME" were written on the lower margin of the counterfeit presentment. The distinguished American then said, "Now add, 'Professor, Clinical Surgery in the University of Edinburgh, etc., etc.'" This latter request was met with a quiet but dignified refusal, and when the question "Why not?" was asked, the response came promptly, "That is supposed to be generally known."

The following anecdote has been frequently quoted by members of the profession intimately associated with Professor SYME. The absolute accuracy of all the details is not fully vouched for by the present writer, at the same time it seems sufficiently probable and characteristic to justify its insertion here. During a meeting of the British Medical Association in Edinburgh, it so happened that Professor SYME performed an operation for the removal of the entire tongue for cancer, one of the many surgical procedures in regard to which SYME's claims to be a pioneer are beyond question. He had performed the same operation once or twice before with but indifferent success, and, in certain quarters, unkind criticisms had been indulged in, and even the justifiability of the operation called in question. On this occasion a large number of the members of the British Medical Association attending the meeting in Edinburgh made it a point to be present at the operation, which all eye-witnesses agree in declaring to have been performed with the utmost coolness and deliberation, the presence of the distinguished strangers having no appreciable effect upon the operator's conduct or manner. After the patient had been removed to his bed in the ward, the audience gave vent to their feelings of surgical admiration and enthusiasm by long and loud applause. The Professor calmly turned around, as he was drying his hands, and pointed to a notice on the wall, requesting order and silence in the amphitheater. This facetious act elicited a fresh burst of applause. He then stepped forward, with the evident intention of saying something, and instantaneously every

second sound, every breath was held, every ear was eager to catch the slightest sound which dropped from his lips. Humor has it that the following was what they heard: "Gentlemen, permit me to assure you that I have reached an age and a position in the profession at which I care neither for censure nor commendation;" and he bowed politely and walked out of the amphitheater. This was the only reply which he ever condescended to tender to his carping critics so far as the operation for cancer of the tongue was concerned.

The accompanying illustration represents Minto House, a building familiar to all Edinburgh people and almost worshipped as a shrine by all students and admirers of JAMES SYME. It was in that comparatively humble building that he established an institution of surgical learning which constituted a challenge and proved to be a successful rival to the Royal Infirmary and all surgical teaching institutions of Scotland. Finding himself, from one cause or another, excluded from hospital facilities, SYME, a young man with comparatively undeveloped fame and meager financial resources, established an opposition school to the great and long-famed hospital, the Royal Infirmary of Edinburgh, and that too at a time when the immortal LISTER, with every advantage of fame, of wealth, of place, and of power, reigned supreme in the medical world of Great Britain. No student, who like myself was intimately associated with Professor SYME in his later days of supreme fame and power, can fail to remember the quiet, dignified expression of pride with which he referred to his experience and achievements at Minto House.

Professor SYME's faculty of recollecting instantaneously the names and faces of former patients was quite remarkable. Two instances of many which came under my own observation I think of sufficient interest to more than one respect to mention here. The first is that of his patient Penman, whose likeness before operation is here reproduced (copied from the collection of SYME's works for which the writer is responsible). This most remarkable tumor of the inferior maxilla was removed along with the entire bone in the year 1822, when the patient was little more than a boy and the surgeon only twenty-seven years old. The inexpressible blessing of anesthesia had not at that time been discovered. The operation proved a complete and permanent success. After the lapse of thirty-four years, this patient, having in the

manifold for obvious reasons cultivated a long and full beard, walked one morning into the Professor's consulting-room, and without saying a word held out his hand to his benefactor of long ago. The writer and all present were then treated to the agreeable surprise of seeing Mr. SYME's instantaneous recollection of his former patient whose case had no doubt through all the intervening years been a matter of justifiable pride and gratification to him.

wrote the following letter to the Editor of the Record in explanation of his views on the subject:

My own feeling is opposed to making any charge for either country visits or operations, when the service is considered in the same, however much the interests of patients may differ. The tradesman may sell his wares as his commodities and limit their distribution to those who are able to comply with the terms of sale. But any man who practices physic or surgery as a profession should endeavor to render the means of relief which he possesses for all

All present were no less surprised than pleased to see how little the operation had injured either his appearance or his articulation. When one regards this great case in all its features, does it not suggest the suspicion that if it were not for the consoling and supporting aid furnished to both surgeon and patient by anaesthetics, nearly, if not quite, seventy-five per cent. of the brave and brilliant surgeons of to-day would be devoting their energies and their bravery to other and less trying fields of usefulness.

As an example of SYME's ability in the matter of recalling former cases which we have space to mention here is the following: A gentleman of immortal fame in the noblest fields of British literature had been operated upon by Professor SYME for a somewhat uncommon form of "cancer" affection and had made a good recovery. After the lapse of several years he decided that it would be wise to again consult the Professor, whom he had not met since the successful conclusion of his former treatment.

The patient, upon entering the Professor's private room, was immediately and without ceremony requested to remove some portion of his apparel and to recline over the examination couch. The Professor, although not entirely successful in recalling his patient's face during the moments which elapsed previous to the actual commencement of the examination, as soon as he cast his eye over the field of operation then he instantly recalled the name and identity of the individual and apologized for having failed to remember fully at first sight so distinguished a patient.

About the time that my immediate connection with SYME and all the pleasant associations pertaining thereto ceased, a keen discussion arose in Great Britain on the subject of professional fees. Mr. SYME, whose liberal notions and strict professional integrity were everywhere known, having been appealed to on this point,

possible available to those who require them, and with this view place the liberality of the risk to the credit of the poor.

The following note unquestionably testifies in the clearest manner to Mr. SYME's consistency in regard to this important side of a medical man's conduct and rule of life. I take pleasure in quoting it here for more reasons than one: First, as bearing testimony to his moral courage and accurate business sense of fair play; second, as a characteristic example of his terse, forcible and elegant style of literary effort; third, for personal reasons which will obviously appear after the note in question has been read:

Mr. SYME presents his compliments to Lord — and begs to say, from the enclosure which Lady — had the kindness to give him on Saturday, he fears there may have been some misapprehension with regard to the professional service which he rendered your lordship. The operation, though undertaken without delay or ceremony, was one of the most important in surgery, directly affecting the life of the patient, and seriously involving the character of the operation. Mr. SYME ventures to hope that Lord — will do him the justice of attributing this communication to its true motive, which is simply to prevent his lordship or himself from remaining in a false position.

(Signed) JAMES SYME.

I have no doubt that the treatment in this rather embarrassing case proved successful. At all events, in the single case in which I tested it, nothing could have been more satisfactory. A very rich man sent me a fee which I deemed inadequate and altogether out of proportion to the value of the service rendered. In acknowledging the receipt of his remittance I ventured to quote Professor SYME's note to his lordly patient and politely asked if he did not think that an ingenuous and gentlemanly method of placing a grateful and appreciative patient and his doctor right in their financial relations to each other. He

...with great good humor and enlarged sympathy. If any of my former pupils or associates should ever have occasion to fall back upon my opinions, it will be only one instance among thousands in which through my humble agency young men of the profession have obtained valuable lessons and helpful inspirations from a great man who was dead before many of them were born. "And he being dead yet speaketh."

Few men in any department of science, medicine or religion, have been more resolute and careful in the matter of maintaining and defending unchanged the principles and doctrines promulgated by themselves than Professor SYME. Consequently it will be readily understood how great an honor it seemed for a young man, at or about the age of twenty-five, to be entrusted with the responsible duty of collecting and publishing, to the best of his ability, the writings which Professor SYME had contributed to medical literature during his long life; especially when *carte blanche* was freely granted to the youthful editor to make his own selections and to use his own judgment as to what should be included and what should be excluded, what should be published just as it originally appeared, and what should be changed. The following extract from Professor SYME's letter of authorization to his former pupil, the writer of the present article, demonstrates and gives full expression to the kindly confidence reposed in him by his venerable teacher. "As to your proposal of republication in America, I have long desired that what I have written should be known in a pure form, and will therefore feel much obliged by your undertaking the task." That the effort, undertaken in the spirit of loving enthusiasm, was not in any sense a failure we have the voluntary testimony of so independent and efficient a critic as the late Professor SAMUEL D. GROSS, of Philadelphia, who, in his autobiography, refers to my edition of SYME's surgical works in the following terms:

As a writer, Mr. SYME was felicitous, his thoughts being always well chosen, and conveyed in a clear, terse, vigorous style. He is best known by his "Principles of Surgery," which was published soon after his entrance into the profession, and which was enlarged and improved in each succeeding edition. The best edition of his works, embracing a complete collection of his monographs, was issued by J. B. LIPPINCOTT & Co., of Philadelphia, in 1886, under the editorial supervision of a former pupil, Dr. DONALD MACLEAN, the present Professor of Surgery at Ann Arbor University, Michigan.

In the preface to that edition I had ventured to quote from the author of "Rab and his Friends," Dr. JOHN BROWN, the following authentic reference to Professor SYME's character:

Everywhere, personally, professionally and publicly, reality is his aim and attainment. He is one of the men—they are all too few—who desire to be on the side of truth rather than to have truth on their side, and whose personal and private worth are always better understood than expressed. It has been happily said of him that he never wastes a word, a drop of ink, or a drop of blood, and he is the strongest, exactest, truest, immediate and subtle intellect dedicated by its possessor to the surgical cure of mankind I have ever yet met with. He will, I firmly believe, leave an inheritance of good done and mischief destroyed, of truth in theory and

practice established, and of credit for the cause exposed and ended, such as no one since JOHN BROWN has been gifted to bequeath to his fellow men. As an instrument for discovering truth I have never seen his penetrability equalled. His mental eye is achromatic and admits into the judging mind a pure, white light, and records an undisturbed, uncolored image, undiminished and unobscured in its passage, and he has the moral power, courage and conscience to use and devote such an inestimable instrument aright.

In regard to this quotation Professor SYME, in a private letter to me, said: "Your preface seems to me to be a little 'loud,' but I dare say it will do for your side of the Atlantic."

Early in the year 1872, I had the pleasure of reading in the Edinburgh papers an exceedingly able and witty speech by Professor SYME on the subject of changing the site of the Royal Infirmary. This was a question with regard to which his own mind had undergone within a very brief period a perfect revolution; having opposed, with all the vigor and intensity of his nature, the whole proposition of "removal," it came to pass that he changed his mind and advocated the opposite plan with equal force and spirit. One week after reading this able statement of his latest views on the subject, the result of which is the magnificent institution now known as the Royal Infirmary and the new University of Edinburgh, I was grieved by information of his having been stricken with paralysis. My mind was at once made up to lose no time in making a pilgrimage to Edinburgh, in the hope that I might once more have the privilege of speaking to him face to face and shaking hands with him; consequently I presented myself one morning at his consulting-room in Shandwick Place, Edinburgh, where he received me with the utmost cordiality. The change produced in him by his attack of cerebral hemorrhage was very sad to behold. His whole condition, physical and mental, was very much changed, but still characteristic words of advice and encouragement were kindly impressed upon me. I was at the time suffering from a peculiarly severe personal affliction, with regard to which he had in previous communications expressed his utmost sympathy, but which in my interview with him I felt for his sake impelled to avoid all reference to. As we parted and I had shaken hands with him for the last time and was turning away from his door, he seized hold of the collar of my coat, and with a quick, nervous movement, turning me rapidly around so that he could look into my face, he said: "Be sure and keep your eye on LISTER and his antiseptic investigations; I feel sure that there is something in them. And remember, sir, look forwards, do not look backwards!" These were the last words I had the privilege of hearing from his lips, and they have served me a useful purpose in more than one trying position, and they will be remembered so long as my memory lasts with emotions of most sincere gratitude and love.

PUERPERAL ECLAMPSIA.

By KEDARNATH DAS, M.D. (Madras),

Medical and Surgical Registrar to the Medical College Hospital, Calcutta, formerly Resident Goodere Scholar, Eden Hospital, Calcutta.

DURING his tenure as Resident Goodere Scholar at the Eden Hospital, Calcutta, the author met with 14 cases of puerperal eclampsia in one year (March 1891 to March 1892) and having 6 more such cases in the course of private practice, he studied all the available literature on the subject which so impressed him with the greater prevalence and higher mortality of this disease in Calcutta as compared with the statistics of America and Europe, that he verily believed that the collection of a large number of these cases would materially assist the study of puerperal eclampsia in its various phases.

With this aim in view he obtained sanction to analyse the records of 10,728 deliveries that took place in the Medical College Hospital and the Eden Hospital from 1848 up to August 1894, and noted that in 4,291 confinements of European, Eurasian, Jewish and Armenian women and in 6,487 deliveries of Hindu, Mahomedan and Native Christian females there were 15 and 86 cases respectively of eclampsia, or a ratio of 1 case of eclampsia to 286 and 75 deliveries respectively.

It will not be without interest to study the subjoined analysis of these 101 cases —

Analysis of 101 cases of eclampsia recorded in the Medical College Hospital, and Eden Hospital, Calcutta, between 1848 and 1894.

From these tables it will be seen that eclampsia occurs much more frequently in Calcutta, and that primiparae are more liable to it than are multiparae, and the suggestion has been put forward that in hospitals only the poorest cases come in, thus raising the ratio. But that would be wrong where the Indians are concerned, since it is only the lowest class of the native population who seek hospital aid, caste prejudices preventing the higher classes from availing themselves of it, and even admitting that a larger proportion of worse cases are admitted, there is still a very high ratio requiring explanation, more especially as to the special frequency of eclampsia in primiparae, even though different views are put forward from time to time of the aetiology of this disease.

That there is a close connection between albuminuria and eclampsia was first pointed out by LIVER, who held that in consequence of renal failure or an inadequate secretory activity of the kidneys some toxic element circulates in the blood, and by this poisoned blood the brain and nerve centres are brought into an irritable condition, which reaching a certain degree, an explosion in the form of convulsions occurs. He furthermore shows that the pressure of the gravid uterus upon the renal vessels induced albuminuria which (1) being specially present in primiparae manifested itself as eclampsia, but (2) disappeared soon after the uterus was evacuated of its contents.

It is urged by Professor CARL DARWEL that the position of the renal veins protects them under all circumstances from any direct pressure by the pregnant uterus which, he thinks, would have to bend very much back on itself before its posterior wall could touch any part of the anterior surface of the second lumbar vertebra, and even if it could reach such a position, it could never compress the right renal vein. But he has forgotten that (1) while the unyielding abdominal wall prevents the uterus from falling forward away from the spinal column (2) the intra abdominal pressure exerted by the growing and pregnant womb alters the relative relation of the abdominal viscera and (3) pressing upon the coils of intestine indirectly exerts sufficient pressure on the renal veins to produce congestion, especially when (4) the peritoneum, which scarcely adequate for such a purpose,

...the kidneys are always ... the kidneys ...

Thus in the kidneys are always ... in females than in males, it is not hard to see how a very little extra pressure might displace the kidneys outwards and thus elongating the renal vessels diminish their calibre and obstruct the flow of blood, and in a multipara this increased abdominal pressure comes into play when (1) though previously pregnant she did not go to full term and therefore did not have her abdominal wall relaxed, (2) when the rigid fibres of her extreme muscular development do not readily yield to the enlarging womb, and (3) by plural pregnancies, hydramnios or an unusually big foetus.

GALABIN says in those cases in which there has been an absence of albuminuria throughout, it appears that increased reflex susceptibility and the presence of a source of irritation, complete the whole pathology, and he is borne out by GÜTZLER, who holds that though the kidney may not be primarily diseased, it serves as a filter to eliminate the excess of albumin which the pregnant woman's blood contains, while PATZS caps this by suggesting "transudation of albumen and autophosphatation," which, TYLER SMITH opines, may depend upon sympathetic irritation of the kidney by the gravid uterus and not upon mere pressure, and while HALASZKEMA attributes eclampsia to compression of the ureters by the gravid uterus, FRANKENHAUSER, who discovered a direct connection between the nerves of the uterus and the renal ganglia, insists that the nervous, and not the vascular, system is the starting point of puerperal convulsions.

The opponents of the pressure theory urge (1) that albuminuria ceases as soon as pregnancy is over by the emptying of the uterus, reverting the blood to its normal condition and removing an inflammatory hypoaemia of the kidneys through releasing the tension throughout the entire aortic system, (2) that albuminuria appearing in the early months of pregnancy (3) may disappear by treatment by purges and bleeding, though the uterus continues to grow, and they note that (4) albuminuria and convulsions not seldom occur in multipara though escaped in the first pregnancy, but they forget that (1) all this may be explained by the pressure theory and (2) by renal hypoaemia pregnancy favors rather than precludes an attack of Bright's disease.

The novel sensations incident to her situation, the dread of her approaching labor and anxiety as to its result naturally make the primipara irritable, mobile and excitable, and this condition of high tension and increased irritability tend to produce a state of erethism of the nervous system strongly predisposing to convulsions, whose actual exciting cause appears to be a poison of an unknown nature retained in the blood, and the accompanying nephritis and consequent albuminuria may be the result of extra work thrown on the kidneys by (1) the depressed vitality of the patient, (2) the pressure of the foetus and enlarged uterus, or (3) by reflex nervous irritation, originating in the pregnant uterus.

As amply proved by eclampsia actually commencing during labor and by the uterine contraction being often the starting point of a convulsion a pregnant or a parturient woman has convulsions in consequence of a recent

nephritis because (1) that form of nephritis is especially severe in its effects of diminishing the excretion of solids and (?) the reflex excitability increases in preparation for the powers of labor which is carried on through reflex irritation in the presence of the ovum, the occurrence of labor pains and the pressure of the foetus in the cervix or vagina.

SPIEGELBERG finds eclampsia dependant on uræmic poisoning through inadequate secretory activity of the kidneys, whether from pre-existing renal disease attaining a dangerous degree of severity by the gravid or parturient condition, or acute affection of the renal vessels, quite suddenly inducing complete anuria by *vaso-motor spasm* through reflex irritation from the uterine nerves, and the increase in the arterial pressure at the onset of the spasm is a consequence and aggravates the disease; but ROSENSTEIN and TRAUBE say that eclampsia only arises when the aortic pressure is suddenly raised in a very hydremic person. This resulting in oedema of the brain, the transuded serum compresses the cerebral vessels and leads to acute cerebral anæmia followed by coma, if the alteration is confined to the cerebrum; but if the middle brain be involved there will be convulsions.

STUMPF, who inclines to the foetal theory, is undecided whether the material which causes the disease is produced by an infectious agent introduced from without or whether it may have been transmitted from the child to the mother, but, taking into consideration the predisposition to this disease in twin and triplet pregnancies and its fatal effect on the foetus as well as the fact that foetal death during pregnancy lessens or entirely overcomes the danger for the gravida, WINCKEL finds that everything seems to point to the intimate relation existing between the mother and the child in regard to the origin of eclampsia.

BRAXTON HICKS advances the view that the convulsion may cause the albuminuria and DEPAUL, LÉGROUX, LEVY, and FORDYCE BARKER agree with him while the researches of MAHOMED which go to show the occasional precedence of the fit over the albuminuria by the kidney already laboring in the pre-albuminuric period, are in harmony with the views of GULL and SUTTON that arterial fibrosis and hypertrophy of the heart react upon the kidney in causing Bright's disease, with an increased liability to convulsions at the menstrual epochs, when the nervous and vascular tension is increased; but while the tension falls when the child dies in utero, all that is wanted to overthrow the balance is an exciting cause which is found in the noxious stuff, retained in the blood through imperfect excretion, and which, diminishing the nutrition of the nerve centres, irritates the diastolic centre and provokes the convulsion.

TARNIER, DE SINETY, LEYDEN and EWART pretty closely endorse the views held by BARKER, who points out that in a large proportion of the cases the albuminuria precedes rather than succeeds, or at any rate is abundantly found at the time of the first fit and not 24 hours after it. The high vascular tension telling upon the kidneys impairs their working powers, leading to an accumulation of noxious stuff, the proceeds of the double nutrition of mother and foetus, and causing irritation both of the kidneys and of the cerebro-spinal centres. The (1) hydremic state of gestation leads to imperfect nutrition of the nervous

centres, increasing both the (2) normal nervous tension and irritability, and (3) the normal vascular tension to (4) promote blood poisoning from imperfect elimination of waste stuff by the kidneys and other excretories, while the (5) granular casts and epithelial scales that accompany the albuminuria are due to the dominant vascular tension of pregnancy making the mucous membrane of pelvic organs undergo an intense degree of hyperæmia (*congestion* but not inflammation) which is marked in the cervix uteri and vagina by (a) deep red and purple coloration, (b) tissue engorgement, (c) profuse shedding of epithelial scales and (d) exudation of muco-albuminous fluid.

In support of the hypothesis of both the nephritis and the convulsions being the result of a common cause, Dr. E. BLANC of Lyons claims to have found in the urine, not the blood, of such patients a *specific bacillus* which is the cause of eclampsia. Pure cultures of this bacillus, when injected into a vein in the ear of pregnant rabbits, promoted dyspnoea and fatal convulsions, but in non-pregnant rabbits they produced nothing beyond local inflammation at the site of injection, while in dogs, whether pregnant or not, the injections induced convulsions from which the dogs recovered after several days. GRAEBE confirms this, but HOFFMESTER and HAGLES tested this point with negative results and DODERLEIN, who altogether disputes the eclampsia bacillus theory, points out the impossibility of procuring urine, even under the most careful method, from pregnant women, without infecting it by the urethral secretions which are rich in bacteria of the most varied variety, and any one of which may have the property of evoking the symptoms noted by BLANC and GRAEBE.

That the temperature and humidity of the air have a very great deal to do with the occurrence of eclampsia in India at least, is very broadly hinted by the fact that of the 101 cases recorded in the Eden Hospital books between 1848 to 1894, nine occurred singly in 9 years and of the remaining 92 cases 44 came in groups within a period ranging from 24 hours to 34 days. The cases were distributed in different months as follows:—

Month.	No. of cases of eclampsia.			Period 1848 to 1894.		
	Period 1848-1894.	1891.	1892-1893.	Average temperature.	Average humidity.	Combined conditions.
January	10	...	3	66.5	69	+1.2
February	8	...	2	71.4	64	+0.6
March	3	79.7	67	-11.3
April	6	1	...	82.4	67	-3.7
May	6	1	...	85.5	77	-12.1
June	3	84.7	86	-6.2
July	6	2	...	83.1	89	-1.4
August	10	82.6	90	-0.5
September	8	2	1	82.7	88	0
October	10	4	3	80.6	85	+8.1
November	17	1	1	73.6	82	+19.0
December	14	1	1	66.7	70	+6.9
Total cases	101	12	11

From this table it will be seen that more cases come in between the months of September and February, when there is a diminution of atmospheric temperature than during the other months.

It is a well-known fact that the functional activity of the skin decreases in the cold weather and the more saturated with watery vapor the air, the sooner does the secretion appear in drops on the skin, while in dry air or in air in motion the formation of drops of sweat is retarded or prevented. Owing to the reciprocal relation between the skin and kidneys the latter secretes less water in summer when the former is active and excretes a good deal more water in winter when the skin is less active. So that the action of these two organs being in inverse ratio, it naturally follows that the diminished activity of the skin does tell severely on kidneys that already have more thrown on them in the role of pregnancy.

The sudden alteration, so common in Bengal in the temperature and humidity of the atmosphere, and to which the women of this country are very much exposed, must interfere with the function of the skin and lead to renal congestion. Imagine the effects of a cold bath on an early morning in an open space with the wind blowing. The average Bengali woman comes out from a closely packed room, takes *such* a bath and immediately after changing her wet clothes has to sit over the kitchen fire to prepare the food for her household. The fact of her being pregnant does not excuse her from either of the duties (*i.e.* bath and cooking) whose sudden alternations expose her to chills and acting as very cogent predisposing factors in the causation of renal congestion, are to a certain degree responsible for the greater prevalence of eclampsia here, in Calcutta especially.

The relative frequency of eclampsia in pregnancy and in labor or that period of gestation when the disease is more frequent cannot be conclusively determined owing to want of efficient statistics, for labor so often coming on as a consequence of the convulsive attacks, many of the cases which really belong to gestation are put down as occurring during labor.

The Morbid Anatomy reveals very little towards clearing up the aetiology. Thus :—

(1) *Brain*.—Serous effusion in 44·4 per cent. engorgement of the vessels in 88·9; anæmia of brain substance in 55·5 and its hyperæmia in 22·2 per cent., cerebral apoplexy in 11 and cerebral softening in 11.

(2) *Lungs*.—Congested in 77·8, pneumonic in 22 and pyæmic infarctions in 11 per cent., while there was no fluid in the pleural cavity of 88·9 per cent.

(3) *Heart*.—Hypertrophied in 33 per cent. and mitral obstruction with hypertrophy in 11 per cent., while in 88·9 the pericardium contained a little fluid.

(4) *Peritoneum*.—Effusion in 11·1 per cent. only.

(5) *Liver*.—Soft and fatty looking in 78, firm and anæmic in 11, and congested in 12 per cent.

(6) *Spleen*.—Enlarged in 45, trabecular structure hypertrophied in 23, its capsule was thickened in 34 and its substance soft in 23, dark in 23, pulpy in 11, firm in 34 and spongy in 11 per cent.

(7) *Kidneys*.—Were congested in 60 and inflamed in 40, hypertrophied in 33, atrophied in 33, hyperæmic in 34 and its cortical substance was fatty in 23, atrophied in 23 and hypertrophied in 12 per cent.

(8) *Ovaries*.—Were injected in 12, cystic in 34, atrophied in 22 per cent., and normal in the remainder.

The treatment.—Consists in (1) controlling the convulsions by *profund* narcosis, (2) speedy evacuation of the uterine contents, (3) diaphoresis with a view to re-establish skin function and reduce the tension.

(1) Chloroform is the sheet anchor, but where the uterus is greatly distended, it should not be exhibited without first rupturing the membranes when bringing the patient under its influence as quickly as possible, and as soon as narcosis is complete empty the bladder, clear the bowels by a large enema and maintain the narcosis which should be a deep one while the uterus is being emptied as rapidly as possible. Enemata of chloral rubbed up with yolk of egg and milk will considerably help the narcosis.

(2). Put on the forceps at once if the os be sufficiently dilated to admit them; but if the dilatation be only slight or not at all, dilate with BARNES' bags and deliver by forceps and after the placenta has also been removed employ some antiseptic intra-uterine douche.

When in doubt as to induce premature labor, bear in mind that as the fate of the child is linked with that of the mother (if the mother dies the chances are that the child must also perish) it is not justifiable to let her run the risk of losing her life or of drifting into grave disease under the expectation of saving the child, and as the mother's life ought to be and is of greater consequence, lose no time in relieving her. Having deeply anesthetized her, dilate the cervix with BARNES' dilators and as soon as this is done sufficiently wide to admit of it, immediately rupture the membranes, apply the forceps and removing the fetus by firm yet gentle traction, see that nothing is left behind in the uterine cavity and genital canal.

(3). After the completion of labor some diaphoretic measures should be adopted to make the skin act vigorously. The vapour bath is most probably the most efficacious means of producing this result, as while it promotes diaphoresis it braces up the system and soothes the patient remarkably.

Of the effects of venesection in such cases very little, if anything, is positively known, but Surgeon-Colonel ROBERT HARVEY very satisfactorily treated several cases in the Eden Hospital between 1885 and 1887, by applying a large number of leeches.

Pilocarpine has been successfully used for this purpose by some obstetricians, but great care and discrimination should be shown in its exhibition. It should never be used during coma, as it produces an abundant flow of saliva and a copious secretion of the mucous membrane lining the air passages, which might lead to urgent symptoms of suffocation. If however it is decided to use pilocarpine, it is wisest to give no more than two doses of a twelfth of a grain each at intervals of quarter of an hour.

DISEASES OF THE CORNEA.

BY C. C. CALVE, M.B., M.S.

*Professor of Physiology, Lahore Medical College,
and Surgeon to the Eye and Ear Out-patient
Department, Mayo Hospital, Lahore.*

TREATMENT OF COMPLICATIONS.

(a). *Perforation*.—When perforation of the ulcer is impending, as indicated by the bulging forward of the floor, the event should be forestalled by paracentesis of the cornea. By doing so, an irregular rupture of the tissue is prevented, and in consequence of the reduction of intra-ocular tension following upon the escape of the aqueous, the reparative process is directly stimulated and further progress of the ulcer is checked. After the paracentesis atropine should be used (eserine, if the ulcer is marginal) and the patient enjoined to keep to his bed for two or three days.

If perforation occurs, our method of dealing with it will depend chiefly upon the size of the opening. If this is small and not situated in front of the pupil, the gap, as has been explained, is closed mechanically by the apposition of the iris to the posterior aspect of the opening, and in such cases it is enough to keep the patient in bed for a few days with both eyes bandaged, in order to allow the margins of the perforation to close up and at the same time to prevent the formation of anterior synechiae. Should, however, a permanent adhesion occur, we must endeavour, in addition to these measures, to break the adhesion by means of eserine alone, or of eserine and atropine used alternately, and to attempt to reposit the iris by means of a probe. If the perforation is a large one and has become occluded by a corresponding prolapse of the iris, the hernia must be repeatedly punctured; and if this does not suffice, it must be snipped off close to the cornea by means of curved scissors. I prefer to make two or more fine incisions into the prolapse by means of a Von Graefe's cataract knife; by this means, the chances of the hernia remaining open for a longer period than would be the case if it were simply punctured are considerably increased; at any rate the method does away with the necessity of repeating the operation too often.

GAMO PINTO recommends that after excision of the prolapse, the aperture should be covered up with a flap twice as large as the opening, taken from the bulbar conjunctiva, the eye to be subsequently covered with a compress bandage, which is not to be removed for three days. By this means a flat cicatrix with little or no synechia is said to be produced (DR SCHWEINITZ).

It is to be remembered that in all these operations the underlying object is not only to evacuate the aqueous humour, but to prevent its re-accumulation until the cicatricial tissue has become sufficiently firm to resist the pressure (VON ARLT).

If the lens also has prolapsed, it is best to remove it.

In case a more or less complete ectatic cicatrix has formed, and provided there is any sound cornea remaining, an iridectomy is to be performed. The main object of the operation, apart from any visual help it may give to the patient, being the prevention of total blindness induced by the gradual distension of the staphyloma through increasing intra-ocular pressure.

(b). *Keratocoele*.—Rest in bed and a compress bandage followed by puncture are sufficient.

(c). *Fistula Cornea*.—This is a most troublesome affection on account of the tendency which it shows of opening up afresh after a temporary closure. We have to depend for a cure principally upon rest in the recumbent posture, a compress bandage, and the installation of eserine to reduce intra-ocular tension. Touching the fistula with nitrates of silver or cauterising it with a red-hot iron, are measures which in intractable cases are recommended—heroic methods, and dangerous in the extreme!

KERATOMATACIA.

Syn. Keratitis Xerotica; Necrosis Cornea; Infantile Ulceration of the Cornea with Xerosis of the Conjunctiva.

This is a suppurative affection of the cornea which occurs exclusively in young children under three years of age. The keratitis is the local expression of a grave constitutional disorder, terminating fatally in the majority of cases, and characterised by a general disturbance of the complex processes involved in maintaining a healthy state of nutrition. The children in whom the affection shows itself are pale and anæmic; they suffer from troublesome diarrhoea alternating with constipation, have a hoarse thin voice, and usually die from sheer exhaustion in consequence of defective powers of assimilation. As might be expected, this marasmic condition occurs chiefly among the children of the indigent poor; in children who cannot obtain sufficient nourishment, who are brought up in unhealthy surroundings, and who are probably in a debilitated condition in consequence of an antecedent attack of measles, scarlatina or other exanthematous fever; hereditary syphilis is said to be in some cases casually related to the disease.

Keratomatacia begins with night-blindness, which is entirely functional, and depends upon torpidity of the retina from defective nutrition. Then the conjunctiva is noticed to have a characteristic desiccated appearance, and to develop triangular patches of xerosis situated on both sides of the cornea. The xerotic spots are due to fatty metamorphosis of the epithelial cells, possibly dependant upon specific microbic action. The xerosis extends over the rest of the conjunctiva, and attacking the cornea in its progress gives rise to insensibility and lack of lustre. A greyish-yellow cloudiness now appears upon the cornea, which rapidly degenerates into a palpy mass; when this is cast off, a large ulcer, which may end in perforation, is left behind. Iritis with hypopyon is a common complication. Whilst the corneal affection is of the gravest character possible, it is a noteworthy fact that the symptoms of inflammatory irritation which generally occur in the severe forms of ulceration, are conspicuous by being almost entirely absent. Both eyes are usually simultaneously affected; sometimes one slightly before the other.

Treatment.—Local treatment is of no avail. Any amelioration of the corneal condition which may take place depends entirely upon improvement taking place in the general nutrition of the patient. The general physician, and not the ophthalmic surgeon, is the proper person by whom the treatment of such cases is to be undertaken.

KERATITIS NEUROPARALYTICA.

This form of ulcerative keratitis arises from trophic causes, leading to degenerative changes in the cornea, dependant upon lesion of the trigeminus.

The trigeminus, through its ophthalmic division, is the afferent nerve of the cornea, and supplies secreto-motor fibres to the lachrymal gland. Hence, lesion of the nerve, in any part of its course from origin to peripheral distribution, such as would be caused by an injury, a tumour or syphilis, brings about corneal anaesthesia and dryness of the eyeball from arrest of the lachrymal secretion.

Following these immediate results, destructive ulceration of the cornea sets in. Two very different views have been advanced as to the relationship existing between the pathological changes which occur in the cornea and the trigeminal paralysis. According to one view, the corneal inflammation is a remote consequence of the nerve lesion being brought about, as is explained later, by the anaesthetic condition of the cornea and the absence of the lachrymal secretion. According to the other view it is the direct and immediate result of the trophic disturbances which ensue on lesion of the nerve.

Taking the latter interpretation first, we have to remark that the most recent experimental enquiry into the subject, not taking into account any possible *specific* trophic influence, which the trigeminus may exercise upon the cornea, seems to point to the inflammatory phenomena being dependant upon vascular changes consequent upon section of the fifth nerve. If ablation of the superior cervical ganglion of the sympathetic is performed after the operation of section of the fifth, no corneal lesions occur, or if they have occurred, their further development is arrested; and this occurs whether the eye of the operated side is or is not artificially protected. This inhibitory influence of the sympathetic ganglion ceases if the carotid is ligatured, or the depressor nerve of the heart irritated (Suitsin).

On the other hand (the first interpretation) it is held that the corneal inflammation, consequent upon section of the trigeminus, is the result of traumatism (SNELLEN and LEUTLEN) or of dislocation (Tener) or of both acting in combination. In consequence of the corneal anaesthesia and the absence of tears, foreign particles are neither detected nor washed away, and hence it is argued that the corneal inflammation is essentially of the nature of an irritative lesion due to trauma. According to this view the so-called keratitis neuroparalytica is only a keratitis e lagophthalmia. In support of this contention, it is urged that ulceration of the cornea does not occur if care is taken to protect the eye after section of the trigeminus, by means of a metallic capsule or a watch glass strapped in front, or by the application of an ordinary protective bandage. *Per contra*, it is to be remembered that simple mechanical injuries of the cornea, unless they become infected, never give rise to anything more serious than a passing business, and that whilst "a protective bandage is a certain preventive of a keratitis e lagophthalmia it is of no avail against the development of a true keratitis neuroparalytica." (FUCHS).

The present state of our knowledge does not warrant us ascribing to the trigeminus or to any other nerve in

the body a specific trophic influence. In STEWART'S words, "no unequivocal proof, experimental or clinical, has ever been given of the existence of such nerves, and therefore unless we adopt the keratitis e lagophthalmic view of the case, it seems more than probable that the inflammation of the cornea is primarily due to the disturbances of nutrition which result from the vascular changes consequent upon the withdrawal of the trigeminal influence; traumata inflicted upon the cornea, which under ordinary circumstances produce no more than an ephemeral cloudiness, act as excitants of purulent inflammation in a tissue which has already become non-resisting in consequence of impaired nutrition.

Symptoms.—The keratitis begins at the centre which becomes dull and denuded of its epithelium. The cloudiness and denudation of the epithelium gradually spread towards the periphery, but never involve the whole of the cornea, a narrow rim being left practically untouched by the ulcerative process. The central parts then become distinctly purulent, hypopyon (pus alone or pus and blood) becomes established, and perforation of the cornea with prolapse, more or less total, of the iris occurs. When the ulcer heals, a flat cicatrix, in which the iris is included, results. The symptoms of irritation are either absent altogether, or if present, are not of a very marked type. Pain is of course absent, in consequence of paralysis of the trigeminus.

Prognosis and treatment.—The prognosis of keratitis neuroparalytica, even in its least serious form, is extremely unfavorable. Treatment is ineffectual. The eye should be protected from the influence of irritants by the application of a protective bandage. Warm compresses and atropine might be used possibly with benefit.

KERATITIS E LAGOPHTHALMO

This is an ulcerative lesion, due to desiccation of the cornea from imperfect closure of the lids (lagophthalmus). It occurs in cases of contraction of the lids, exophthalmus, paralysis of the orbicularis palpebrarum, and in such diseases as cholera, typhoid and pyæmia, where the patient remains in a semi-unconscious condition, with the eyes only partially closed.

In consequence of the continuous evaporation which takes place in these cases, the conjunctiva and cornea are found to be covered in the exposed inter-palpebral fissure with yellow crusts. If the corneal crust is removed, the membrane beneath appears clouded; the cloudiness, which is due to the presence of an infiltrate, rapidly increases, and by the disintegration of the superficial layer, becomes converted into an ulcer, with its long diameter horizontal. Iritis and hypopyon are generally present, and perforation of the cornea with its sequelæ is very liable to occur. If the patient does not succumb, and the ulcer does not go on to perforation, the case may terminate with no worse result than a permanent opacity. Symptoms of irritation, such as pain and photophobia, are usually slight.

Treatment.—The indicatio morbi requires the closure of the affected eye to prevent desiccation, for this purpose the lids should be fastened together by means of strips of sticking plaster, and the eye to be carefully bandaged up, as a further precautionary measure.

HERPES CORNEÆ (HORNÆ).

Herpes of the cornea presents itself in two forms: (a) Herpes corneæ catarrhalis and (b) Herpes zoster corneæ.

Both these affections are characterised by the formation of small vesicles upon the cornea. These consist of circumscribed elevations of the anterior epithelium caused by serous exudation, and are thus very different from the efflorescences of phlyctenular keratitis, which consists of masses of lymphoid cells. As a rule the herpetic eruption is composed of a number of vesicles arranged in groups, or in rows like a string of beads.

In consequence of the fact that the wall of these vesicles is extremely thin, consisting of epithelium only, it is seldom that the surgeon sees the eruption in its vesicular form; what is seen are the minute superficial ulcers, more or less round which, early in the course of the disease are formed by the breaking down of the epithelial wall. The surface of the ulcers is anæsthetic.

Corneal herpes, which appears in paroxysms, and is generally unilateral, is always accompanied by marked symptoms of irritation. There is active congestion of the conjunctiva, severe lachrymation, photophobia, and pain. These symptoms are relieved or entirely disappear with the rupture of the vesicles.

(a). *Herpes corneæ catarrhalis* occurs in acute inflammation of the respiratory passages, such as disease of the posterior nares and pharynx, bronchitis, pneumonia and influenza, and sometimes in febrile affections like whooping cough, intermittent and typhoid fevers. Associated with the corneal affection there may be herpetic spots upon the eyelids, face, nose, and lips.

The prognosis of herpes of the cornea is extremely favorable. The ulcers, provided the nature of the disease is recognised, and suitable treatment adopted, soon heal (7 to 10 days), leaving only a fugacious opacity behind. In neglected or severe cases, they may by infection take on the character of a keratitis dendritica.

The treatment is in the main that of corneal ulcers generally—antiseptics, protective bandaging, and the use of atropine or eserine. The general condition of the patient should at the same time be attended to, and if necessary tonics and quinine internally administered.

(b). *Herpes zoster Corneæ*.—Is a local manifestation of herpes Zoster ophthalmicus. It differs, so far as its course is concerned, from herpes corneæ catarrhalis, in its longer duration, in the tendency to the formation of a more lasting opacity, and in the fact that after rupture of the vesicular envelopes the symptoms of irritation do not disappear.

The treatment is the same as that of herpes catarrhalis.

KERATITIS BULLOSA.

Syn. Keratitis Pimpliguis Corneæ.—This is an affection allied to the two forms of herpes above described. It is a rare disease, and occurs in almost every instance, secondarily to glaucoma, or irido-cyclitis. It is characterised by the formation of one or more large blister-like vesicles upon the cornea, filled with serum; the wall of these is formed by the anterior epithelium and by connective tissue newly formed between the epithelium and Bowman's membrane. In consequence of this the bullæ do not break down with the same ease as do the small

vesicles of herpes. When the bullæ are of comparatively small size and of short duration, the disease is designated as a *keratitis vesiculosa*.

The cause of keratitis bullosa is not understood, Von ARLT considers it as a variety of interstitial keratitis consecutive to glaucoma or irido-cyclitis, or a large corneal cicatrix. Since in nearly every case the disease is attended by increased intraocular tension, it has been suggested (FUOSS and BRUGGER) that the cause of the disease is to be found in the stagnation of the lymph circulation caused by obstruction of the normal channels at the limbus. Hence the cornea becomes oedematous, the lamellæ are dissociated, and the fluid pushing forwards lifts up the anterior epithelium from Bowman's membrane in the form of one or more blisters.

Keratitis bullosa is always accompanied by violent symptoms of inflammation. There is acute pain, photophobia and lachrymation; ciliary injection, however, is slight. By the rupture of the blebs a hazy abrasion is left behind; this may go on to ulceration. The disease shows a marked tendency to recurrence.

Treatment.—This consists in puncturing or excising the vesicles. By this means, we succeed in mitigating the inflammatory symptoms, but do not prevent the recurrence of the eruption. This can only be effected by the performance of an iridectomy to relieve the causative increase of tension. When this fails, the affected eye, which for visual purposes is already a useless organ, must be removed.

—:0:—

IGNORANCE THE CHIEF CAUSE OF DISEASE.

By HARA KALI SEN, C.M.S.

Paiganj, Dinajpur.

If ignorance is bliss 'tis folly to be wise
Is a senseless couplet plied before our eyes,
For IGNORANCE I hold the worst crime neath Eastern skies.
It is the chief cause of all our social ills
With Superstition's dregs our cup of woe o'erfills
And proves the horrid curse that countless millions kills.
By cruel, heartless rites, not by the *shastras* taught,
And quite opposed to Reason yet by Custom brought
To bear on untaught thousands, though with danger fraught.

Ignorance and superstition are twin sisters, under whose blasting influence are committed the most heinous crimes and diabolical acts. Under their potent sway all thoughts of kindness are crushed out of the human breast. Men became more ferocious than tigers, and women so heartless that mothers willingly threw their new-born babes into the sacred Ganges or urged their widowed daughters to immolate themselves on the funeral pyre of their sons-in-law. Men offered human sacrifices to propitiate the Earth-goddess, and fathers smilingly "aliced," their living children to pieces. 'Twas but the other day a man killed his own son in cold blood because he dreamed that his god wished him to do so.

Medicines are useless and sanitary science a waste of energy, so long as superstition and ignorance are allowed

to rule the roost. Not long ago, cholera broke out in a tea garden in Assam where the native doctor in charge offered the coolies medicines and advice how to act to prevent a further spread of the disease. "Oh! what good will your medicines do? they said. "We know the real cause of this disease, and will take steps to put an immediate stop to it." That very night they most cruelly tortured a poor woman whom they accused of invoking the cholera by her witchcraft.

As here at Raiganj, so also all over India, the ignorant classes firmly believe that every disease is caused by an evil spirit which must be expelled by *mantras* (i.e., incantations) by a recognized *mahut* (exorcist). The ceremony of *mahuty* (exorcism) is performed at night, preferably when the patient, after offering *puya*, (a form of worship) is besmeared with mustard oil and joba flowers and made to stand between the *mohuts* who shriek their *mantras* at him or her the livelong night, and violently shake him or her every time he or she is overcome with sleep.

Crass ignorance like this is to be deplored, but it cannot be helped till education paves the way to understanding the benefits to be derived from effective sanitation and trained medical aid. It may seem strange, but it is nevertheless true that there are many rich peasants who die without medical attendance, not because they cannot, but because they do not want to get a doctor to treat them.

Legislation can do no good on these points, as the people are too ignorant to grasp the benefits promised, and just now financial difficulties will not allow Government to engage the enormous staff necessary to explain sanitary requirements, and refuse cremation or burial without *post-mortem* examination of those whose deaths are not supported by sufficiently legal medical certificates.

Besides it will be no easy task to convince the masses that there is no real virtue in their phylacteries and medical charms dispensed by their *hathies*, *mahuts*, and *phalkholnewalas* who trade on their credulity.

Well the uneducated masses pay dearly with their lives and healths for their ignorance, but what excuse have the educated B.A.'s and M.A.'s of our Universities for adhering to *caste* and *astrology* which retard progress and promote disease and early death?

Caste.—Before the revival movement no educated Hindu dared to openly speak in favor of *caste*, that abominable system that has principally contributed to our downfall. The Brahmins were particularly interested in its revival since it gave them a powerful hold on the people who worshipped them as gods, but it is surprising to see the many educated Hindus, who are staunch advocates of *caste*, which they even try to afford scientific explanation for the necessity of, by saying that "caste controls the law of heredity," which upholds social distinctions of human beings and rules that good parents beget good children. But there is neither moral nor hereditary law that says that a bad man must be respected simply because he was highly born of good parents. How expect an educated Sudra to honor, obey and respect an educated and immoral Brahmin for no other reason than that he (the latter) belonged to a higher caste.

In a previous article I showed how caste deteriorated the physique, intellect and courage of Indians by prohibiting intermarriage. I will now show how caste is detrimental to health, wealth and wisdom.

No matter how hungry he may be, a Hindu must not eat or drink anything, however nutritious and necessary, that has been prepared or even touched by any one who is of a lower caste than himself. Hence he cannot cross the seas for purposes of study or of commerce, and an effectual barrier is thus placed against his education and prospects of wealth from foreign climes, while international trade is strictly forbidden.

Expenses cheapen when a number of persons club together for "mess"; but caste privileges will not always allow this, and the majority of us who hold official appointments must live separately because all our office mates are not of the same caste. A man drawing Rs. 40 to Rs. 50 per mensem has to engage a servant to do his odd jobs for him, but as he cannot eat from this man's hands, he has to also entertain a Brahmin who will do nothing more than cook for him—and this means throwing away Rs. 10 a month or starving, because he is afraid of caste. In short, the present Hindu system of caste is a pernicious evil which demoralises the people in many ways and has not a single redeeming feature about it.

Astrology.—Is the source of endless expense and ever-increasing anxiety to its advocates (some educated men too) who will do nothing, not even take a dose of medicine without first consulting the almanac to see whether it is an auspicious hour and date for such act.

Man is ever curious to peer into the future, and astrology trades on human curiosity by pretending ability to reveal that future. If heavenly bodies do exert any influence of good or evil on any days of the year, those days and influences should affect Christians, Mahomedans and Hindus equally. If a European can travel with perfect safety or undertake anything on an 'unlucky' day, why may not a Hindu do so also.

Just to show how little credence I place in astrology, I always pick upon an "unlucky" day when I have to start for a railway journey with my family, and I have not yet suffered harm for defying the prognostication of the stars.

Aekology.—The mind is its own self, and in itself can make

A hell of heav'n and heaven of hell

Wrote the grandest of all English poets, and the mind can so control the body as to produce various symptoms of ill health, which do not differ a particle from the symptoms of true disease. These "mind-formed diseases" which are usually the result of fear or a too vivid (though often unwitting) imagination may proceed ad extremes or disappear under faith and suggestion.

The majority of the Indian races are uneducated and ignorance begetting superstition, the ignorant man never stops to think for himself or to look into the laws of cause and effect but accepts accidental coincidences for positive truths, and attributes everything he cannot thoroughly understand to the supernatural. Hence the Hindu belief in *mantras* instead of medicine for the cure of disease.

To the shame and sorrow of our Hindu nation educated Hindus of the "caste revival class" place implicit belief in everything that appears in Sanskrit script or in the *shastras*. They never stop to enquire whether the *shastras* they credit are the ancient and genuine articles of Hindu religion or those newly manufactured to suit interested motives. It is enough for them that the writing is in Sanskrit and some carry the theory of "every thing is possible and nothing impossible" so far as to actually believe that if mango trees are subjected to certain processes, they will produce not mangoes but plantains, and this because they chanced to read some such nonsense in some Sanskrit book.

What makes the savage worship the fire, the storm, the water or some powerful phenomena of nature and try to propitiate them by sacrifices? Ignorance prompted by fear and the superstitious craving in every human breast for something to reverence.

Many an educated Hindu is compelled by social and spiritual fear to retain his superstitious and place implicit faith and reliance in the accuracy (???) of his religious books, which it would be a deadly sin for him to question or doubt. This too ready faith in what others say or pretend to quote from religious teaching gradually deprives them of self-confidence, self-reliance and self-respect, and obliterates the power of thinking for themselves.

Treatment.—Reason must be made to occupy a higher place than mere authority or superstition and the uneducated must be taught to think for themselves by being shown that many things they looked upon as *magic* were readily and easily explained by natural philosophy. After which they will be able to see through the superstitious stupidities of mythology and be released from their blind thralldom.

Their minds could then be expanded by the secular and scientific education of the West, so that they may grasp and retain the solemn truth *mens sana in corpore sano*. And then, but not till then, the sanitary condition of our villages will be properly attended to and our peasantry saved from many preventible diseases, that under the present *regime* of ignorance and superstition cuts their lives short.

For the preservation of health and inducement to longevity two things are necessary: knowledge wherewith to shake off superstition, murderous bonds, and wealth. One without the other is powerless to save us from the pangs and woes of many fell diseases. And with efficient education both these desiderata will and must surely come.

ENERVATION.

MARGAIN has recently made a study of a certain morbid condition related on the one hand to hysteria, on the other to neurasthenia, and which includes in point of fact many phenomena met with in neuropathic patients, and aptly included under the title of "enervation." The author points out that owing to modern conditions of life the effects of overstrain, the multiplicity of emotions, and, it must be admitted, the glaring defects of modern education, enervation promises to become more and more frequent, and persons so affected seem to become less able to cope with it. Loss of energy, sleeplessness, defective digestion, and irritability are among its leading symptoms. Against this, a treatment both moral and physical must be directed, the general health must be carefully watched, for it would seem that such patients are under the influence of a form of auto-intoxication, due, it may be, to constipation, confinement, or alterations in nutrition produced by excesses.—*Brit. Med. Jour.*

A MIRROR OF PRACTICE.

DEFORMED PELVIS: SYMPHYSEOTOMY: DELIVERY BY FORCEPS: BOTH MOTHER AND CHILD SAVED.

By T. M. SHAH, L.M.S.,

Chief Medical Officer, Junagadh State.

A MAHOMEDAN female, 9th pregnancy, full term, been in labor last three days.

3 P.M. *Vaginal examination*; membranes said to have ruptured early this morning. Head presenting and is jammed in the cavity of pelvis, strong pains but head unable to progress. Pelvis contracted. Tuber ischii approximated and there is an exostosis about the size of a walnut, on the concavity of the sacrum reducing the pelvic diameter and obstructing the progress of the head. Natural delivery was out of the question, and patient was advised to go to hospital, but her relatives objected and would have rather she died. Her previous labors had been protracted and delivery always effected by version.

11 P.M.—The contraction of the pelvis was so great that delivery by forceps or perforation was impossible and Caesarian section seemed to be the only course to be adopted. But I decided to try symphysiotomy before performing such an operation, which is generally so fatal in its results.

The patient being placed under chloroform, and the urine withdrawn by catheter, a Syme's bistoury, was passed underneath the skin and the pelvic joint divided. The bones separated to the extent of an inch, sharp venous bleeding ensued from the wound. Next the long axis-traction forceps was applied, but the blades did not lock, however, by traction with semi-locked blades, the head was brought down to the outlet when the blades slipped. The short forceps was then introduced, blades did not lock, but by traction the head was born, the body following after a few minutes. Though the child was not breathing, there was pulsation in the cord, so this was speedily ligatured and divided, and then artificial respiration and alternate cold and hot water immersion succeeding in reviving the infant.

There was free bleeding from the wound, which was arrested by pressure, iodoform was then dusted and an abdominal bandage applied. Pulse 108 before and after the operation, of fair volume and strength.

24h.—Pulse, 112, Temperature 100°. No bleeding, vomited during night, did not sleep well. Bowels not moved. Urine not passed freely. She was prescribed—

R	Mist. quinine	3℥i No. (886)
	Tinct. Chlor. Co.	3i.
M.ft.	Mist. 3 doses.			
R	Tinct. Digitalis	2℥, 20
	Liq. Ammon. Acetat....	3iv
	Pot. Nitrate	30 grs.
	Aque	3℥i.

112h.—She is doing well. Child restless and crying. Repeat Mist.—

R	Castor Oil	3iv.
	Aque Ment. Pip.	3i et.

12th.—Temperature 100°. Pulse 100. Discharge yellowish and foetid. Pubis painful. Pain in the right thigh. Slept badly during night.

R	Liq. Ammon. Acetat.	3iv.
	Potasse Nitrat.	3ss.
	Tinct. Digitalis	3ss.
	Liq. Morphie	3ss.
	Aque	...	ad	3iii.

Make three doses.

14th.—Temperature 102°. Pulse 120. Lochia same. Pubis painful. Appetite is impaired. Tongue is dry and coated.

R	Glycerini	3ii.
	Spt. Vin. Gallici	3vi.
	Liq. Ammon. Acetat...	3vi.
	Tinct. Digitalis	3ss.
	Spt. Aether Nitrosi	3ss.
	Aque	...	ad	3iii.

M.ft. Mist. three doses.

16th.—Temperature 100.4° Pulse 110. Right side of pubis swollen. Repeat mist with Liq. Morphia m20.

18th.—Temperature 98°. Pulse 90. Patient able to sit up without much inconvenience.

R	Pulvis Doveri	grs. xv.
	Sodæ Bicarb	grs. xv.
	Quinise Sulph.	grs. v.
	Bismuth Subnit	grs. 3v.

Ft. pulv. three doses.

R	Tinct. Opii	3i.
	Argenti Nitratis	grs. ii.
	Glycerini	3ii.
	Aque	3iv.

Ft. injection for rectum.

20th.—Temperature 98° 4. Pulse 94. From this time she improved steadily and in a short time was able to resume her usual duties.

Remarks.—Deformity of the pelvis was considerable and this case points out the utility of the operation of symphyseotomy in such circumstances. In all I have performed symphyseotomy on 4 cases. In the first case although pelvic deformity was very great, her next delivery was natural. In the second case delivery was safely effected by incising the symphysis pubis, but the patient died subsequently from the effects of septicæmia. This is the third and successful case, and a fourth operation has also proved successful.

A STRANGE CASE OF HÆMORRHAGE

By JOHN V. JAMES, D.G.M.C.

Assistant Civil Surgeon, Mysore.

I WAS sent for to see an old lady suffering from hæmorrhage. I found Mrs. M. bleeding from the eyes, nose, mouth and ears. The blood flowed profusely from the mouth and nose and trickled from the inner canthus of the eyes and from the external meatus of the ears.

The nares had been plugged by the medical man who had been called in first but the hæmorrhage was still very severe. I administered drachm doses of extract ergot liq. every second hour and syringed the nostrils with a solution containing alum and tincture ferri and thus

formed two clots which acted as natural plugs, and stopped the hæmorrhage from the nose. But the hæmorrhage from eyes and ears and mouth continued even after four doses of the ergot. I then tried a mixture containing acid sclerotic, acid gallic, tincture hydrastis and tincture atropanthi, and the two doses given within the hour checked the hæmorrhage. There was a slight return the next day, but the same mixture was used and met with success. I then ordered a mixture containing caloi chloridi and tincture hydrastis which was given three times a day, and there was no further trouble.

The patient being very anæmic was put on a course of iron and has been keeping very well since then.

Mrs. M. is now 68 years old. She was 16½ on the day of her marriage. She first menstruated at 13 and was very regular except for the last two years before the menopause, which occurred at 51, when she suffered from menorrhagia twice a month for a period of three to seven days each time. She had 10 children, all the labors being easy ones; she had two miscarriages.

She remembers only one attack of illness, and that was measles in infancy. Kept splendid health otherwise.

The first attack of hæmorrhage, like the present one, occurred when the patient was 55 years old, and lasted 7 days; second attack after 9 years lasted 15 hours only, third attack 1½ years after second; fourth attack ½ years after third; fifth attack ¼ year after fourth; sixth attack on 26th January 1896.

Prodroma in all seven attacks were severe headache for days together, feeling of great weight on head, tightening felt from temple to temple, and general malaise.

Patient remembers no injury to the head. Last child born when mother was 40.

Patient's father had severe hæmorrhages from the nose every summer as long as she can remember. Her mother had several mishaps and severe floodings which patient remembers very well.

She feels great relief after the hæmorrhage has occurred, but suffers from loss of memory for months after each attack.

Sight and hearing are very good, even at present. Heart, lungs and liver are quite sound. Ergot produces pain in the lower part of the spine and in the legs and uterus, but a course of iron very soon cured these evil after-effects.

Judging from the above history, the patient appears to be "a bleeder," and the hæmorrhage seems to come from the base of the brain and apparently seems nature's prophylaxis against cerebral apoplexy.

OVARIAN DROPSY: OVARICTOMY. RECOVERY.

By ASSISTANT SURGEON T. M. SHAH, L.M.,

Medical Officer, Junagadh State Hospital.

LIRI GOVA, Hindu female, *et.* 22 years, has suffered from a gradually increasing abdominal distension for the last three years. She presents at present all the signs of the presence of fluid in the abdomen. The circumference of the latter is 66 inches, and the distance between the pubis and the umbiliform cartilage 26 inches. She weighs 137 lbs. Liver, spleen, kidneys and heart appear to be normal.

Was confined three years ago, (the child died within a week); Has not menstruated since. Uterus and cervix normal. She then noticed a bulging on the right side of the hypogastrium, which has gradually attained the present dimensions.

Has lost flesh considerably, and is unable to attend to her work.

Ovariectomy.—24th May 1897, 12 A.M. All antiseptic precautions were taken and urine withdrawn. After being placed under chloroform, an incision was made in the linea alba, commencing just below the umbilicus and carried about five inches downwards. On opening the peritoneal cavity a quantity of clear fluid escaped. The cystic wall was white and traversed by blood vessels, the omentum being firmly adherent to it. The cyst was punctured by a Spencer Wells' trochar cannula and some grumous fluid let out (57lbs), some fluid also escaped externally. The cyst was then drawn out. It was slightly adherent to the abdominal walls in parts; but the entire omentum was firmly attached to the cyst, and it had to be literally torn from it, necessitating four ligatures—two to bleeding vessels and two to the mass of omentum. The pedicle was narrow and connected with the left broad ligament. It was ligatured, divided and allowed to drop in.

The peritoneal cavity was then thoroughly sponged.

The abdominal wound was then closed by silk sutures, including the entire thickness of the muscular wall and the peritoneum. Iodoform dressing, boracic lint, oakum, pad and bandage were applied. Morphia $\frac{1}{4}$ grain injected hypodermically after operation.

30th.—Temperature 100°, pulse 98, urine withdrawn twice a day by catheterisation, bowels not moved. Vomiting was checked by small doses of arsenic.

4th June.—Urine passed voluntarily, temperature 98°, pulse 90.

30th.—Wound has completely united by first intention, liver is enlarged to the extent of 2½ inches below the costal margin, tender to the touch. There is another induration in the left side below the splenic region. It is movable but not painful, and rolls about according to the position of the patient. She now takes ordinary solid food.

The hepatic and other enlargements gradually subsided by treatment in about a fortnight's time, and she made a thorough recovery.

THE TREATMENT OF VERTIGO KNOWN AS MENIERE'S DISEASE.

The writer reports the case of a man 58 years old. The patient who had previously been quite well was taken suddenly one morning in June 1893, with a violent vertigo, having all the features of Meniere's disease. Following this the patient complained of a persistent noise in the right ear, and of a continuous vertigo for which he was given quinine in large doses with excellent results. Apropos of this case, the author takes up the history, causation, lesions and diagnosis of MENIERE'S disease. He points out the rôle played by hyperexcitability of the labyrinth in the production of vertigo, and dilates on the efficacy of quinine in the treatment of the auricular forms of vertigo. The medication should be given in ten grain doses once or twice a day for a period of at least a fortnight.—DR LA TOURNETTE.—*Post Graduate.*

THE Indian Medical Record.

16th April 1898.

SOME THOUGHTS ON THE DELHI POISONING CASE.

UNDER the above heading, the *Pioneer* for the 1st March devotes four columns to the discussion of the orders of the Punjab Government on the enquiry into the circumstances attending the death of the late Mr. LONDOUN FRANCIS MACLEAN, C.E., Superintending Engineer, who died at Delhi on the 13th November 1897.

It is indeed most painful for any one, especially for members of the medical profession, to read such a record of lamentable carelessness, and we must all express to Mrs. MACLEAN the deepest sympathy with her in her irreparable loss. It is said that "a fault confessed is half atoned," and we must admit with shame, that the deceased died, as the Lieutenant-Governor says, "partly through mistake, and partly through disregard of rules," on the part of Government officials in the civil department of the Indian Medical Service. The "mistake" was that the Civil Surgeon of Delhi wrote a prescription in which he ordered "160 minims of extract of *nux vomica*," instead of *structure*. The "disregard of rules" was that the compounder of the Police Hospital at Delhi, "instead of referring for orders, changed minims into grains in the prescription book, and dispensed the mixture accordingly." He was able to do this, because the Hospital Assistant sent him the keys of the almirah containing poisonous drugs by a servant, although he (the H.A.) was "responsible for their being dispensed under his personal supervision." The orders of Government to the Inspector-General of Civil Hospitals in the Punjab are: (1) that the Civil Surgeon shall be transferred from Delhi to a smaller station; (2) that the Hospital Assistant shall be reduced to the third class for two years; (3) that the compounder shall be dismissed.

In commenting on these orders the *Pioneer* naturally asks "on what principles of equity are these punishments thus graded?" In paragraph 8 of the Government letter, Sir MACWORTH YOUNG writes:—"In the year 1894, in consequence of a delay of 2½ hours in the dispensing of a prescription in the Police Lines Dispensary, Dr. DENNIS wrote an order as follows:—"The compounder should be told that in case of any complaint in future as to the preparation of medicine he will be severely punished." The *Pioneer* concludes:—"Finally, we should like to ask whether, while the leading Civil and Military officials in Delhi have (with somewhat questionable taste) been giving a *farewell dinner and dance* to Dr. DENNIS, anything has been done in the matter of a pension to the widow of Mr. MACLEAN?"

"Leading Civil and Military officials" in India are not always conspicuous for good taste, and as another example of this, we may allude to the famous Ootacamund fancy-dress ball, the chief feature of which was a dance of devils and angels. Against this outrage the Bishop of Madras protested, and was supported by the "press," but "society" only laughed, and now while a widow is mourning, her Delhi acquaintances dine and

dance with the author of the prescription which caused her husband's death. This callousness denotes a state of public apathy which is quite as serious as the carelessness which made the existence of such a prescription possible.

The Punjab Government order on this painful case does not quote the fatal prescription word for word, but merely comments on details of its omissions and corrections, but the profession ought to be informed for what illness *nux vomica* was ordered, and the whole prescription should be published word for word as it was written, for unless this is done, it is impossible to know what dose was intended to be given. "160 minims" seems a curious quantity of anything, especially of a poisonous drug, and if the compounder put "160 grains" of extract of *nux vomica* in the medicine, no wonder a fatal result ensued. It is extraordinary that the compounder should not have been aware of the dangerous property of this quantity, so the profession ought to be told how long this man had been a compounder, and what sort of education or training he had received. We should also be furnished with a copy of the prescription which procured this man a censure in 1894 when a delay occurred of $2\frac{1}{2}$ hours, for unless we know the ingredients, we cannot tell whether the censure were merited, or otherwise. Moreover, the exact date in 1894 should be mentioned, and the time at which the prescription reached the compounder, for without all these particulars it is impossible to know if $2\frac{1}{2}$ hours would be much of a delay, or not. For instance, if pills were ordered, one can understand that the time of preparation would vary with the season; as a pill, which might be easy to make in dry weather, might be difficult to complete nicely in the rainy season. All compounders are over-worked and underpaid, so it is not surprising that as a class they are indifferent to their work. It is preposterous that a man, whose duty it is to make up medicines and dress wounds, should have no better pay than a menial servant, whose duty it is to wait at table, dust furniture, brush clothes, &c. We have ascertained that this particular man was formerly a vaccinator, but on the reduction of establishment was made a compounder, being trained for the same at the Civil Hospital, Delhi. He has been 12 years in the service, and was in receipt of the princely salary of Rs. 10 per mensem. To state this fact is to condemn it, but there is such a mania for economy, that executive officers will not ask for proper pay for their subordinates, knowing that administrative officers will not recommend it, and Government will not sanction it. It is important that the reason for the delay in 1894 should be published, as it may prove to be the fault of Government, not of the compounder. Many years ago, when the present writer was at Peshawar, (a very large station as every one knows), an incident occurred which impressed him very much. He wrote a prescription one day for an officer's child about 11 A.M., but about 4 P.M. he received a note from its mother to say that no medicine had been received, though she had sent the prescription at once to the hospital, which was quite close to her house, not two hundred yards distant. He went at once to the hospital to see about this delay, when he met the Hospital Assistant at the gate of the hospital very much flurried

and exhausted, as he had had a long ride and no breakfast.

The prescription was for an ordinary cough mixture, and for a piece of spongio-piline. The mixture was soon made, and the poor Hospital Assistant was very sorry that he did not send it at once to the officer's house, promising the spongio-piline afterwards, as he had none in store. Instead he went all round the station, both cantonments, civil lines, and city, but at none of these hospitals, military or civil, could he find any spongio-piline, so at last in despair he tried the jail, where he was at once given a large roll of it, which he brought to show to his own medical officer, who (like the subordinate) was astonished and disgusted to find that a common "hospital-necessary" like this was denied to the tax-payers and to the defenders of the State, but was supplied lavishly to convicts. Observers of Indian manners and morals might with some justice conclude that it was held to be a more heinous offence to kiss your neighbour's wife, than to kill your neighbour by misadventure; for the latter offence you will probably be moved from a larger to a smaller station, but if you kiss your neighbour's wife, you are compelled to retire from the service on a trifling pension.

—:O:—

HEREDITY IN RELATION TO LIFE ASSURANCE.

In his presidential address to the Life Assurance Medical Officers' Association, HERMANN WASSER Esquire, M.D., F.R.C.P., pointed out that the non-appearance of parental disease in different children is not positive proof always that they have not inherited disease, since occupation, habits of life and climatic influences may so react on the germ, which is endowed with invisible peculiarities for good or evil, as do not call it into manifest activity or hold it in complete abeyance for one, two or more generations until the arrival of conditions favorable to its development, when the disease may reappear with all virulence in the 2nd, 3rd or 4th generation. Hence he advises enquiry into the life-history of the uncles, aunts and grandparents as well as of the parents of the "proposer," and divides assurance "lives" into three classes: (1) *Average lives* where unless carried off by infectious diseases or accidents the greater number die between 60 and 72 years of age (2) *Long lives*, which are of great and profitable importance to insurance companies, range from 75 to 90 years and more, and may be cut short by infectious disease and accidents; but they frequently survive even those that the *average lives* succumb to, and in which both malignant and constitutional disease take a much slower course in them. A peculiarity in some of these long-lived families is that all the organs and functions do not retain their vigor in an equal degree, while old age shows itself sometimes even early in the hair, teeth, senses, generative organs or even in the memory and higher functions of the brain: but insurance offices need not mind them much, as these organs and functions are not vital, and even flaws, such as quiescent phthisis may be counter-balanced by good points such as concomitant gout; since gout is somewhat antagonistic to phthisis. (3) *Short lives* constitute those families, the majority of whose members die before 60, whether from recognized diseases or from ill-defined conditions

coming under the head of a general breakdown. Insurance offices have to be very careful with members of such families, which more often prove disastrous to them. Children under age, belonging to such families are a particularly heavy risk. Such lives must either be declined or insured only for a limited period under a special system as "under average" lives; but as it would be immensely difficult to lay down hard-and-fast rules for rejecting or accepting such proposals or adjudging the amount of extra premium that must be paid since there are many exceptions in members of such short-lived families, and change of occupation, of habits of life and of abode, and still more of the country, exercise a powerful influence on the constitution, and in order to take them as "good lives," their personal history and condition as well as their surrounding influences must be good.

Next as to special conditions and recognised diseases, he notes that (4) *Phthisis* is a powerful element, whose degrees of risk, however, vary considerably according to (a) the number and nearness of relatives who have died from it, (b) age of the proposer, and (c) his personal condition, past history and manner of living which have many varieties. If only a brother or sister or some collateral has died and a good proportion of the others are surviving, the risk is almost nil, or may be only slightly increased, provided the elements (b) and (c) are satisfactory; but if one parent and many collaterals have died, the risk is already greater and is further increased, if besides parent one several brothers and sisters have died, while it is still more so if both parents have died and most so if in addition to the parents, one or two grandparents or their brothers and sisters have been victims of the disease. (b) The risk of inheritance is greatest up to 30, diminishing gradually up to 40, becomes comparatively small from 40 to 50. (c) A thin, weakly person with a phthisical family taint ought to be rejected, while to be accepted the proposer should lead a healthy active life, devoid of bad habits and besides having the appearance of health and strength, he ought to be, and to have been, free from hæmoptysis, pleurisy, glandular inflammations and swellings, affections of the apices, frequent catarrhs or so-called scrofulous, but generally tuberculous, diseases of the joints. The tendency to (5) *emphysema* and (6) chronic *bronchitis* has a decided element of heredity, but mostly for death in later life. If only one parent has died of these at over 65 years of age, the risk need not be provided against, but if there are several deaths below that age, a moderate extra should be charged or an endowment policy proposed. (7). Fixed rules cannot be laid down for *carcinomatous diseases*, but every case requires consideration on its own merits, as though, decidedly inheritable cancer affects females much more than males, and usually occurs in the latter part of life, it sometimes appears earlier in the offspring than it had done in the parents, and kills females earlier than it does affected males. So that a young person may have easier insurance terms than one near middle age. (8). If only one of the parents has died from *diabetes*, which is inheritable, and the proposer is below 40, a moderate extra should be charged; but if he is above that age and his personal health, manner of living and other circumstances are satisfactory, the extra may be waived. Proposers under 30 should be declined or accepted only with a heavy increase. (9) If

glycosuria shows itself in a proposer tainted with heredity, a heavy addition is necessary, unless he belongs to a long-lived family; but every case of *glycosuria*, that cannot be controlled by dietetic management, ought to be declined. (10). *Gout* is so complicated a question in which the personal element is so important, that every case demands individual consideration. To a female proposer easier terms may be given. A life with gouty inheritance that has already suffered from gout, demands an extra more or less heavy, for life or for an endowment policy, but if he be middle-aged and a small quantity of albumen be found in his urine, he should be declined, more particularly if he is not very careful as regards eating and drinking, and does not lead an active healthy life. (11). Though there have been several early deaths from *rheumatism*, which is much more frequently acquired than inherited, still more frequently than not, rheumatism is compatible with longevity and so also with (12) *rheumatoid arthritis* or *arthritis deformans*; but as there is a kind of alliance between (13) *rheumatic fever*, which is decidedly inheritable, and *phthisis*, protection by an 'extra' is required if the proposer is young and has lost near relatives from the disease. (14) Heredity is not adequately appreciated with regard to the *heart and blood vessels*. *Angina pectoris*, fatty degeneration and valvular diseases of the heart may be traced through several generations; but this last is due partly to the hereditary element in rheumatic fever in earlier life and partly to atheromatous lesions in the later stages of life. The questions regarding apoplexy and paralysis show that the proposal forms acknowledge the hereditary tendency of degeneration of the small blood vessels, not only of the brain but also of other organs of the body. (15) A number of morbid tendencies, such as *hemophilia*, *hemorrhoids*, *biliary* and *renal concretions* and *Bright's disease*, do exert a hereditary element, no single one of which is strong enough to warrant an 'extra' charge, but if a number of such flaws co-exist or have occurred in the same history, the case requires a more serious consideration. (16). Then there are other less tangible, but for all that, very risky hereditary conditions (such as unusual susceptibility to some microbic poisons with fatal results) which cause severe loss to Insurance Companies but scarcely justify loading on a premium. (17). An important matter is the family tendency to a strong or a weak brain, since the *nervous system* offers the most remarkable instances of heredity in all its functions, and a vigorous brain can pass unhurt through great emergencies under which a weak brain generally breaks down from "shock" or "overwork." But so long as such lesions are not associated with paralysis or other flaws with a special tendency to shorten life, assurance officers can scarcely protest against them as risky. (18). *Dipsomania* and other forms of alcoholism allied to it are doubtless hereditary, and their occurrence among the parents or older brothers or sisters, should induce the strictest enquiry into the personal history, manner of living and all the surroundings of the proposer to protect the company against risk. More especially, as a curious circumstance of their heredity is, that the effects of alcohol are mostly very similar in the children and in the parents, even when the parents died while the children were yet very young. In some, epilepsy or an insatiable craving for drink, that no moral influence can subdue, in others a suicidal, homicidal or kleptomaniacal tendency.

In some tendency and in others pronounced aberrations. But all inheritable defects are unsatisfactory for the purpose. That exophthalmic goitre is inheritable and requires no effort, varying with the other circumstances of the case, and the possibilities of change of air with avoidance of worry and over-exertion; but the duration of paralysis agitante mostly five long.

The tendency to epilepsy may show itself in the children in various taints, either as epilepsy, or insanity, or dipsomania or uncontrollable passions, &c., that rapidly wear out a highly strung nervous organisation, but tabes, which is not surely the effect of syphilis, is less inheritable than epilepsy, and so on.

Then there are peculiar forms of trembling and tremors that occur in some family histories, and have led to the proposer being declined from fear (a wrong one) that the trembling was due to alcoholism, or commencing disease of the centres.

Therefore it is absolutely necessary to carefully judge every case on its own merits, and take all points (especially affections of the nervous system) connected with the proposer into consideration, as also to closely look into marriage ties, since intermarriage of tainted relatives always increases the risk. This relates to all morbid taints, but most prominently to those of the nervous system.

THE HISTORY OF PLAGUE IN HYDERABAD. SOME IMPORTANT OBSERVATIONS.

II.

In our issue of 16th March we traced the history of the plague in the Nizam's dominions up to the 22nd February, when the Plague Commissioner, Surgeon-Colonel EDWARD LAWRIE started on a tour of inspection in the infected districts.

Honnabad and Kalliani were found free from plague, Sirsi was found infected; 83 deaths having taken place; the search parties employed under Dr. NAIDU had discovered no cases between this place and Hyderabad.

In company with Mr. STEVENS, the Commissioner, visited all the plague-stricken villages about Gunjoti, and arrived at the conclusion that this district was the most important focus of infection in the Nizam's dominions.

In this district 550 deaths from plague have been reported as follows.—

Gunjoti	233
Umerghi	172
Terrori	14
Chincholy	1
Bulsoor	42
Sirsi	41
Marej	16
Nagarai	8
Others	12
Total	550

But by those best qualified to judge, this number is from 250 to 400 short of the actual number of deaths that have taken place.

In these infected villages all the orders of the Government of India with regard to evacuation and disinfection had been carried out by Mr. STEVENS.

Dr. LAWRIE was struck by the resemblance of the cases he saw to disease produced by inoculation with

some putrid organic (probably animal) poison as in "dissecting wounds, though he admits the resemblance is not complete. He reports an interesting case where Hakim COWASI while dressing a case of gangrene, inoculated himself with some of the discharge through a scratch in the ring finger of the left hand, and developed symptoms almost identical with plague; he had a large tube in the left arm-pit and an abscess under the pectoral muscle.

Many of the plague cases had superficial suppurating buboes, the discharges from which infected directly the clothes, bedding, and floors of houses.

From the 25th February, systematic examinations were made of the dust and scrapings of the floors, walls, and roofs of houses in various villages. The floors are mostly constructed as follows: the earth is raised, rammed in and "leaped" over (plastered over with liquid mud mixed with cow-dung).

At first only the houses marked as infected were examined. Accident, however, revealed the fact that the plague bacillus was to be found in large numbers of the floors of houses supposed not to be infected, and further investigation showed that in Gunjoti 50 per cent. of such houses were actually infected.

That the bacillus found in these supposed uninfected houses was actually the bacillus of plague, was proved by inoculation experiments.

The following facts were established by the examinations of, and inoculations with, the plague bacillus:—

(1). The plague bacillus was invariably found in the dust and scrapings of the ground of houses known to be infected, i.e., houses in which plague patients had been ill or had died. Infected houses were examined in Sirsi, Gunjoti, Umerghi, Kajuri, and Bulsoor.

(2). The plague bacillus was found in the dust and scrapings from the floors of more than 50 per cent. of the houses which had previously been regarded as uninfected.

(3). A healthy rat was inoculated with dust scraped from the ground in a supposed uninfected house (No. 28 uninfected) in which the plague bacillus was found to be present. The rat died within 36 hours, and on post-mortem examination it exhibited the usual signs of plague, viz., enlarged glands, congestions and hæmorrhages, and the plague bacillus was found in abundance in the peritoneal cavity, in the glands, and in the blood.

(4). The plague bacillus was found in grain which had been lying on the ground in an infected house.

(5). The plague bacillus was not found in the dust or scrapings of the roofs and walls of any of the houses examined.

(6). The bacillus was not found at a depth of more than an inch below the surface of the ground.

(7). The plague bacillus was found in dust taken from the floor of a house (No. 28, uninfected) immediately after the ground had been heated by lighting on it a thin layer of cow-dung fuel sprinkled with kerosine oil. A rat inoculated with dust from this floor immediately after the burning remained well until it escaped from its cage on the fourth day.

(8). In milk inoculated with dust containing the plague bacillus, a growth and multiplication took place. The day after the inoculation from one to two bacilli to a field

could be counted, on the fifth day from 45 to 55. In five days therefore each bacillus had increased to about 50.

(9). The plague bacillus was not found in the dug up portions of the ground (floors) after they had been burnt in the kiln method.

Dr. LAWRIE thinks that these facts tend to prove his contention that the virus of plague is most probably a putrid animal poison which falls to the ground, and does not spread through air, or even through water, unless it is excessively filthy, but is taken into the human system mainly by inoculation.

They further pointed the way to a uniform plan for the destruction of the plague infection.

DEMOLISHING THE PLAGUE BACILLUS.

The plan adopted was the burning of the floors and scrapings of the lower parts of the walls.

After considerable experience, what is called the kiln method was introduced by Mr. STEVENS.

In this method the floors of the houses are dug up to a depth of one and a half inches; the dug up material is carefully removed to a short distance from the house and made into a kiln, with cow-dung fuel underneath and all round it, the lower layers being sprinkled with kerosene oil, this is set on fire and allowed to burn itself out.

With the aid of the microscope Dr. LAWRIE holds that it is always possible to determine if a house is infected; but as 35 minutes at least is required, the method could not be applied in extensive large villages, and it was therefore decided that the only safe plan was to burn all the floors in the infected villages.

All the plague-stricken villages in the Gunjoti district have been evacuated and the isolation and segregation camps are in charge of competent medical officers, while the work of burning the floors is proceeding apace under the direction of Mahomedan gentlemen, who are thoroughly interested in the work.

The kiln method has met with the entire approval of Sir KHURSHID JAH's Taluqdar, and of all the village officials and villagers.

It will be an anxious time for the Nizam's advisers, when the time comes for the re-occupation of the evacuated villages, and any sign of recrudescence then will be eagerly looked for, nor can the danger of re-infection from Sholapur be overlooked.

PROPHYLACTIC INOCULATION.

Dr. LAWRIE is anxious that every opportunity should be given to test HAFKINS's prophylactic inoculations in the Nizam's dominions. To this end we learn that Professor HAFKINS has trained Dr. MULLANAH and Mr. SYED MAHOMED in his laboratory; and that they will carry out the operations in the Hyderabad State.

There can be no doubt as to the wisdom of this step, and we have every confidence that the inoculations will, if possible, be carried out in such a way as to throw as much light as possible upon their true value. We will look forward to the results with interest. Our chief fear, or rather hope, however, is that the measures already taken by Surgeon Lieutenant-Colonel LAWRIE and his coadjutors have been so practical, systematic, and thorough, that there will be no chance of subjecting the inoculations to a satisfactory test for the plague will cease.

THE LIFE AND TIMES OF THOMAS WAKLEY, FOUNDER OF THE LANCET.

ABOUT this time an event occurred which was eagerly seized upon by WAKLEY. On the 12th February 1831, there appeared in the *Lancet* a letter stating that the surgeons of His Majesty's navy had been notified by circular that they were not to attend the King's levees; it subsequently appeared that the obnoxious circular had been issued under a grievous official mistake, and it was almost immediately rescinded.

WAKLEY stigmatised the circular as a deliberate and cold-blooded insult, which the profession as a whole was bound to resent, and he urged in the *Lancet* that the

following Monday, at the Royal College of Surgeons, the occasion of the delivery of the Hunterian oration would be a good time and place for a public demonstration of sympathy as well as for a public decision upon the steps to be taken towards the annulling of the offensive order.

In consequence a large number of members attended at the College to protest; this assembly was an entire innovation amounting to an assertion that the Community, and not the Council, could decide the business of the day.

Before the Council with the Hunterian Lecturer appeared, two resolutions had been put and carried; the Council, however, refused to receive them, and the meeting terminated by WAKLEY saying that at any rate the members had done their duty and it remained for the Council to do theirs.

The action of the Council being considered unsatisfactory, WAKLEY the following week begged the profession to again attend at the College to decide upon what course should be taken.

The Council issued a notice to say that the doors would not be opened till a quarter to four, and that no public discussion would be allowed.

As soon as the doors were opened, WAKLEY and his followers filled the theatre and a scene of considerable confusion followed.

At four o'clock the President, Council, and a posse of Bow Street officers entered the theatre, the uproar was so great that no one could be heard.

A Bow Street officer was sent to order WAKLEY out, but WAKLEY said the Council had not the least power to remove him, whereupon the officer returned saying: "Mr. WAKLEY knows perfectly well what he is about."

As the uproar continued, the President and Council left. WAKLEY then addressed the meeting and implored them to preserve a quiet behaviour, a Chairman was elected and WAKLEY continued his speech, and resolutions were passed condemning the action of the Council.

Some minutes later Mr. BELFOUR, the Secretary, entered and handed WAKLEY a paper bearing an order from the President for him to leave the theatre. He refused, when suddenly a number of Bow Street officers rushed in and seized him by the collar, arms and legs and proceeded to expel him by force, in the tumult that ensued one of them aimed a blow at his head with a truncheon which providentially missed and fell upon his shoulder. Upon WAKLEY's removal the other members proceeded with the business for which he had convoked them and formed a resolution to wait upon the Lord Chamberlain.

WAKLEY was unable to get a warrant against the Bow Street office who had assaulted him, and these legal proceedings terminated.

It is characteristic of WAKLEY that after one powerful outburst of rage, his allusions to the personal indignity that he had undergone became infrequent and dispassionate, after the first feelings of natural wrath and insult had subsided he was not ungrateful to his enemies for providing him with so forcible a proof of his contention that they were autocratic, careless of the rights of their commonalty and unscrupulous in their methods of preserving their own position as irresponsible rulers.

During the next three years WAKLEY saw reason to change his methods; he had done as much as he could in his private capacity; he saw that he could not expect much from the co-operation of the profession, he decided to give a larger scope to his work of reform, to transfer the scene of the struggle from Lincoln's Inn Fields and the columns of the *Lancet* to Westminster, in short to aim at the introduction of a new Medical Act.

WAKLEY's life and interest was so much bound up in the *Lancet* that there is but little to say about his private affairs. One of the first persons to recognise the great position that he was securing for himself and the great future before the *Lancet* was his father-in-law, Mr. GOODCHILD; he came to the assistance of his literary

venture; this timely aid turned the scale of fortune in WAKLEY's favor, and as soon as circumstances permitted, he left the house in Norfolk Street and settled in the pleasant neighbourhood of Thistle Grove. In 1828 he moved into No. 35 Bedford Square, the house that is associated with all his public life as Member of Parliament for Finsbury and Coroner for Middlesex.

WAKLEY was an open-handed, cheery, and humorous man; he delighted in good company, and at his fortnightly gatherings for whist or chess he gathered round him a large number of staunch friends, who were attracted by his eloquence, his audacious defence of popular rights, his determination, self-confidence, and kindness of manner. He was assiduous in the reception of his political allies, medical and lay, and paved the way carefully for his future election.

WAKLEY's great aim in entering Parliament was to reform medical abuses; he felt that the medical profession needed a voice within the "House" to make medical matters, often of a severely technical kind, distinct to the comprehension of the legislators.

This one object had not sufficient interest for the electorate to enable him to command their votes, so he entered into the general reforming spirit of the time and pledged himself to support a large number of general measures.

He was selected as a proper person for a seat in the first Reform Parliament by JOSEPH HUME and WILLIAM CORBETT. After failing twice he was finally elected member for Finsbury in January 1835.

WAKLEY was very literal as well as very honest in his interpretation of his Parliamentary duties; he was at first an infrequent speaker, although an assiduous attendant at Westminster, but his taciturnity was dictated by the fact that the special causes which he had been instructed by his constituents to plead did not come before the "House" nor did matters affecting the medical profession present themselves.

Within six months, however, a great opportunity came for a display of his talents as a speaker, and he was not slow to seize it.

The case was that of the Dorsetshire labourers, one of whom were arrested and tried for the crime of "unlawfully administering a secret oath." They were sentenced, to the astonishment of the country, to seven years' transportation.

WAKLEY's speech in their behalf lasted two hours and a half, and throughout the whole time he held the closest attention of the "House." When he resumed his seat the general applause was so hearty and unrestrained, that he could not but feel that he had achieved a real oratorical triumph, and in the most critical assembly in Europe.

Although the motion was lost on a division, the speech had a good result; the matter was not let drop, and within nine months the laborers had received a free pardon.

WAKLEY rose to make his first great speech a comparatively unknown man, with a record not calculated to win him the good graces of an assembly ever jealous of the manners of its members. He sat down with an undisputed claim to first class oratorical powers, and with a recognised position in the "House" as a fit and proper person for its Councils.

COMMENTS AND NEWS.

THE TAMASHA OF DR. CROMBIE'S DEPARTURE.

BRIGADE-SURGEON LIEUTENANT-COLONEL ALEXANDER CROMBIE, M.D., I. M. S., late Surgeon Superintendent of the Calcutta European General Hospital, and general medical practitioner in this city, has retired from Government service and has gone to the land of oblivion, the goal of most retiring officials. For 26 years he has had a good time in the Indian Medical Service. If a few wire-pullers and office-seekers of the Bengali community have given our departing friend some small degree of satisfaction by filling a hall with students to wish him good-bye and to tender him the customary Oriental lip-salve of verbose adulation, then Dr. CROMBIE has earned a "reward." The two native meetings that were "got up" for Dr. CROMBIE, were a farce in every sense of the term. The address presented to him was a pitiful piece of water-coloring of the usual Indian style. To attempt to cause such tinsel tamashas to pass for an expression of universal good-will and professional confidence, is a parody on facts and common sense. To describe Dr. CROMBIE's career as a success "in the cause of science, medical education and medical literature," is simply to belie his own modest assertion that he had "done very little" in any of these directions. We maintain that the entire absence of the non-official European practitioners from the "address" meeting and the "union" in the India Club, in spite of all having been invited to be present, and further the absence of nineteen twentieths of the Indian practitioners from both these functions, prove that the object for which they were "got up" was not a popular one. We maintain that the closing chapters of Dr. CROMBIE's connection with the Presidency General Hospital,—the public disapproval of the working of the hospital so frequently expressed in the daily press, the lesson to be drawn from the prohibition of his successor from engaging in private practice, the barrenness of clinical reporting from the General Hospital, the large amount of official time spent *outside* the hospital—all these facts serve to emphasise the assertion that the statements made by a few time-servers may well be relegated to the realms of imagery and Oriental verbosity of a purely lip-adulation type. It is not fair that hypocrisy of this stamp on the part of a few should pass counter for genuine and well-merited praise, and in view to preventing these somewhat frequent misleading exhibitions of public *décor* towards medical officials, many of whose aims and merits may be summed up in the carrying out of Lord CHESTERFIELD's advice to his son—"Make money my son, &c., &c." and who allow their public duties a very second-rate consideration where the shaking of the branches of the "Pagoda Tree" of private practice is concerned—we find it necessary to call a spade a spade. Surely the recollections of the meanness and double-dealing of some of the official ring-leaders of the Indian Medical Service Congress, and the *rapport* about the spiteful tyranny of the methods employed by some officials when countersigning the medical certificates of private physicians, ought to serve to recall the innate character of many an official, and these lessons should never be forgotten by non-officials till a more honest and wholesome atmosphere pervades the life and conduct of medical officials in their demeanor towards their non-official brethren.

MUSCOORBIE DOCTORS, OFFICIAL AND NON-OFFICIAL.

THE following parody on a familiar rhyme was suggested by reading the petition of nine Muscoorie medicals, who complain that a tenth member of the medical faculty, to wit,

the Civil Surgeon of that station, in (Bangalore State and) occasionally interfering with the practice of the many private doctors—

TEN LEARNED DOCTORS.

I
Ten learned doctors, sipping Coca wine,
One grew nervous, then there were nine.

II.
Nine learned doctors, wrangling in debate,
One turned homesick, then there were eight.

III.
Eight learned doctors, "At home from eleven,"
One went rinking, then there were seven.

IV.
Seven learned doctors, medicines they mix,
One said his practice, then there were six.

V.
Six learned doctors, keeping folks alive,
One prescribed wrongly, then there were five.

VI.
Five learned doctors, alcohol forswore
One kept the pledge too long, then there were four.

VII.
Four learned doctors, eager for a fee,
One "advised gratis," then there were three.

VIII.
Three learned doctors, heavy work to do,
One fled to Dohra, then there were two.

IX.
Two learned doctors, quarrelling like fun,
Fought each other on the Mall, that left one.

X.
One learned doctor, triumphing alone,
Turned Civil Surgeon, then there were none
(Alas! no learned doctors.)

The above doggerel appeared in our northern contemporary, *The Morning Post*, over the initials A. N. G., and emphasises our contention of the unfairness and handicapping of private enterprise by State competition still further. "There is something rotten in the State of Denmark" when nine doctors as well qualified as the Civil Surgeon and with more local acquaintance and knowledge are unable to hold their own against him, owing to numerous advantages which Government gives its officers. This question, however, will soon engage the attention of the Government of India, and then perhaps some British ozone in the precincts of St Stephen may kill the official bacillus altogether!

THE BOMBAY GOVERNMENT AND THE PLAGUE.

As we were the first medical journal to publish the result of MONS. HAFKIN's prophylactic method and to pronounce definitely in its favor, we can regard with certain feelings of self-complacency the recent change of front of the Bombay Government.

We hear that inoculation has at length been recognised, and further, that persons who have been inoculated within four months are to be exempted from segregation.

The attitude of the Bombay Government reminds us of the negro potentate, who, when visitors appeared at his court, regarded them in silence with a fixed and steady stare which lasted for an hour or so; after undergoing this ordeal the visitors were informed that the king saw them.

The Bombay Government has at last condescended to see MONS. HAFKIN and his prophylactic inoculations.

It is of course unfortunate that a very terrible eye-opener, had just been administered to the Government in the shape of serious riots, the result of long pent up feelings of irritation and resentment in the native mind; and though we have no wish to even suggest that the Government acted

under a sense of coercion, there can be no doubt that had they adopted their present method at an earlier date, these riots would not have occurred.

This in itself amounts to a grave charge of mal-administration. We have before remarked that in this matter the religious and caste prejudices of the native community weigh by no means a negligible quantity, this has been proved over and over again, and the Government must have been well aware of the existence of a smothered feeling of dissatisfaction and resentment, and the direction in which it was tending.

It is difficult to understand the position so long held by the Government and the stubborn obstruction to prophylactic inoculation, to say that inoculation was on its trial and could not be accepted as proved, is simply no answer at all.

To refuse to put a thing to the proof, because it has not been already proved is absurd; but little advance would be made in modern scientific medicine, or indeed in anything else, if such a narrow-minded rule of conduct was universally followed.

The Bombay Government had the means and opportunity of putting this matter to the test, and of deciding a question, the importance of which cannot be overestimated, once and for all; and it is not too much to say that this was the least that was expected of it by all civilised communities.

It has already failed to do its duty in this matter, to humanity in general, and history will no doubt in the future tell us why.

In the meantime, the brunt of popular indignation has to be borne by the Plague Committee, and they are a much maligned body, if they are entirely blameless.

THE INSPECTOR-GENERALSHIP OF CIVIL HOSPITALS, BENGAL

THIS important administrative office has seen so many changes in its incumbents during the past half decade that the interests of Indian Medical Service officers have suffered greatly thereby. Not only has the service suffered but our hospitals, our medical educational institutions, and of course the public, have all felt the harmful influence of a constantly changing administration, a lack of continuity in medical policy, and a lack of knowledge of the personal abilities and fitness of officers for certain onerous appointments. Instead of having a medical administrative head, the Sanitary and Medical Departments of Bengal have been governed and directed by the Bengal Secretariat. All these difficulties have arisen through the want of a strong hand to guide the helm in medical matters in Bengal. Colonel ROSS was an excellent Surgeon-General, but he was made to feel the pressure of Secretariat interference, and strong as he was, he broke down in health, and so his able plans for reform all fell through. Now we find Surgeon-Colonel HENDLEY installed at the head of affairs medical in Bengal. Dr. HENDLEY's reputation as a most vigorous, painstaking, and able administrator, is most encouraging to those who look to the fountain head for the initiation of some settled plan of hospital and educational work, and for an honest and meritorious method of filling vacant appointments in our public institutions. Recently things have gone on at a scandalous pace of mismanagement, and the Bengal Secretariat is seriously to blame for its reckless disregard of the public needs of our institutions, inasmuch as it has recently overriden the recommendations of the medical department, and filled a few excellent posts by men utterly unfit to hold them, and by such arbitrariness has imperilled the success of more than one public institution in Bengal. We cordially hope

that the Government will be able to afford the most important offices for the service, and that the Calcutta Medical College Hospital and the Presidency General Hospital will be thoroughly considered in regard to their duties to the public and to medical education. We trust also that Surgeon-General Henshaw will boldly consider the question of prohibiting State-paid doctors from engaging in general and family medical practice in Calcutta.

THE BLOOD IN MALARIAL FEVER. ANOTHER VIEW OF THE CASE.

WE have seen that HANS ZIEMANN denies phagocytosis in malarial fever. H. VINCENT, professor at Val-de-grace, medicine major of the second class holds a different opinion. (We quote from the same journal as before):—

In a paper entitled "The Role of the Leucocytes in Malaria," he says that he found after many detailed observations that a considerable leucocytosis occurred, in exactly the same way, in regular quotidian, tertian, and quartan ague, and chiefly at the beginning of the attack.

That this leucocytosis is so transient that it may easily be overlooked.

That it gives place to a hypo-leucocytosis, so that often the number of the white blood corpuscles is less by two or three times than it was before the attack, and on the following day it may still further decrease if the patient has not taken quinine.

This initial increase and later decrease of the leucocytes is so pronounced that it is sometimes possible to determine the exact stage of the attack by a simple examination of the blood.

In malaria it is the work of the large leucocytes with a single nucleus to destroy the exciting agents of the disease.

The question whether the amoebae are still alive at the beginning of this process VINCENT answers in a decided affirmative, for the very lively movements of the pigment, which is plentifully distributed throughout the body of the parasite, seems to point to a suffering (?) condition.

Further, fully developed plasmodia with lively amoeboid movements were observed in the leucocytes 22, 26, and even 48 hours after the blood was taken, while shortly after the taking of the blood, no developed plasmodia were found but only black pigment and a few leucocytes.

This seems to prove with certainty that the amoebae can grow and develop in the white blood corpuscles, outside of the living body.

FACTS ABOUT SMALL-POX AND VACCINATION.

THE following points have been embodied in an official circular issued by the Council of the British Medical Association.—

1. THE mortality from small-pox is much less now than in pre-vaccination times.

2. The greatest diminution in the small-pox mortality is found in the early years of life, in which there is most vaccination.

3. In countries where there is much vaccination and re-vaccination relatively to the population, there is little small-pox.

4. In classes among which there is much vaccination and re-vaccination there is little small-pox.

5. In places where small-pox prevails, it attacks a much greater proportion of the unvaccinated than of the vaccinated, especially where the vaccinations are comparatively recent.

6. In houses invaded by small-pox in the course of an outbreak not nearly so many of the vaccinated inmates are attacked as of the unvaccinated in proportion to their numbers.

7. The fatality-rate among persons attacked by small-pox is much greater, age for age, among the unvaccinated than among the vaccinated.

8. It cannot be truthfully alleged that independently of vaccination small-pox is a milder disease now than in former centuries.

9. The degree of protection conferred by vaccination corresponds to the thoroughness with which the operation has been performed, three or four marks being much better than one or two, and a large mark much better than a small one.

10. Sanitation cannot account for the facts above set forth.

11. Though isolation of small-pox cases in hospitals is a useful auxiliary to vaccination, it is no substitute for it.

12. Vaccination is very safe.

13. Calf lymph is now available to boards of guardians, etc., for the vaccination of every child in this country.

THE LATE EXAMINATION FOR THE ARMY MEDICAL SERVICE.

SAYS the *British Medical Journal*:—"We published last week the results of the recent examination, which showed that, notwithstanding the undoubtedly clever official expedient of mixing up the Indian and army examinations together, only 21 candidates were secured for the latter, to fill the advertised 40 nominal vacancies. The result of the new scheme must be very disappointing to the official opponents of the Army Medical Service, who had hoped by a little manipulation to stave off reform. Under the new system the public are not told how many competitors went up for each branch of the service, and what was the proportion of failures; but it is not difficult to see that, but for the new scheme, the last examination would have been an even more lamentable fiasco than its predecessor. There appear to be good grounds for the inference that a considerable number of the 21 successes for the army were drawn from those who had not been successful in obtaining commissions in the Indian Service, for the highest candidates for the former very suggestively just follow after the lowest for the latter. Then, quite half of those successful in the army did barely more than secure qualification by a minimum of marks, so that it is hard to say whether the failure in quality is not even greater than in quantity. It is rumoured that there were originally 48 army candidates, which, if true, proves that more than a half were found physically and professionally unfit. We think the public may take it that had not a certain proportion of the rejected of India been secured for the army, there would practically have been a mere handful of candidates for that service. To what a miserable state has the Army Medical Service fallen? Mr. BRODBROOK announced to the House of Commons last week, as was stated in the *Journal* of February 19th, that the steps which will be taken to put the Department in a better position will shortly be announced, and it is certain that reform cannot be long delayed.

THE WONDERFUL MALARIAL PARASITE.

THE following extract from the *Munchener Medicinische Wochenschrift* shows in what a state of inextinguishable confusion the minds of experts still are, regarding what to the ordinary observer would appear to be some of the simplest details.

HANS ZIEMANN, of Heligoland, in a paper entitled "New Observations on Malaria and the Blood Parasite of Malaria."

In this paper he confirms the results of previous observations which were communicated by him to the Naturalists Society at Frankfurt in 1896.

"The growth of the malarial parasite is concurrent with the breaking up and proliferation of pigment, which, after the resulting division, again surrounds itself with a colourless zone and the remains of the protoplasm of the original body.

No so-called spores are formed.

There is no disappearance of nuclei and nucleoli as MANSION asserts:

LAVERAN's bodies are merely moribund or sterile forms.

The curative effect of methylene blue is disputed when spontaneous cure occurs, phagocytosis takes no part in it.

The mode of infection is in no way yet cleared up.

The parasites of tertian and quartan fever are similar, but morphologically different forms.

Some of these data strike at the very root of what has hitherto been accepted without question. The formation of spores was considered such an important characteristic that the generic name *Sporozoa* was given to the parasites.

The bodies known as LAVERAN's are the crescentic forms whose development we believe forms the foundation of all the hypotheses of MANSION and his followers.

Clearly HANS ZIMMANN must be ruled out of court, or our experts must alter their views.

THE LATE SIR RICHARD QUAIN.

THE *Times*, in a notice of Sir RICHARD QUAIN, whom it speaks of as one of the most conspicuous figures of his generation, tells the following story of his early career: "Quite early in his career he was requested by Mr. WAKLEY, the then Coroner for Middlesex, to make a *post-mortem* examination in a case, which attracted considerable attention at the time. A man who for some months had been in a desponding frame of mind, came one day to his wife, and displaying to her a piece of paper labelled 'arsenic,' said that he had swallowed what it contained; and that 'it was all over with him.' The man was taken to a hospital, where the resident officers applied all the most approved remedies for arsenical poisoning with great vigour, but the man died in spite of them. The druggist, from whom the parcel had been procured, said that the man had asked for arsenic, but in consequence of his manner and appearance, cream of tartar had been supplied under an arsenical label. A quantity of arsenic was, however, found in his stomach. Not satisfied with this Dr. QUAIN pursued his enquiry and found that no arsenic had passed out of the stomach into the intestines. He inferred that what was found had been introduced by the stomach pump or some similar means after death had occurred, and it was ultimately shown that this had been done by the resident medical officers at the hospital, who seemed to have some notion that the case was not one of arsenical poisoning at all and who had endeavoured to conceal the error into which they had fallen. The sentences with which Dr. QUAIN suspected the truth, and the skill with which he brought it to the test of experiment, were much appreciated."

LINGUISTIC QUALIFICATIONS IN INDIAN MEDICAL APPOINTMENTS.

It is remarkable how coincidences sometimes happen. We are informed—perhaps incorrectly—that Colonel JARRET, the famous military specialist in Oriental languages, has been appointed Major-General of Division of Aldershot! His chief claim to this important command being his exceptionally high linguistic attainments!! We now learn with some pleasure and small surprise that Surgeon Lieutenant-Colonel GEORGE SPIERS ALEXANDER RANKING, M.D. (1879), M.R.C.S., Eng. and L.S.A. Lond. (1874) has been elected to be the successor of Dr. CROMBIE, as Medical Superintendent of the European

Presidency General Hospital, Dr. RANKING, has special qualifications of a certain kind, inasmuch as he possesses a facile knowledge of Oriental languages and a versatile genius in theatrical and other performances. Dr. RANKING has been popularly known for some time as the Secretary to the Board of Examiners in Oriental Languages, and the general public of Calcutta has been accustomed to regard him as a most talented amateur actor. It is worthy of note that popularity in these always commendable accomplishments, have apparently counted for something in one of the most coveted medical appointments in Bengal. From a professional and a public point of view, we would have thought that for so important a position as that of Chief Physician to a large civil hospital, the Bengal Government would have displayed a keener desire to select a gentleman of large practical experience in the profession, but it seems that just as in Aldershot so in Calcutta strange things happen, in fact in medical appointments in Bengal under the Secretariat régime, it is the unexpected that generally happens.

A STORY OF RICOED.

We read in the *Philadelphia Medical Journal* a story of the late Professor RICOED, of Paris:—"In a little town near Orléans lived, more than 60 years ago, a celebrated bone-setter, curing all the ills of humanity, and who enjoyed a great reputation in that country; no doctor had ever attempted to supplant him. One day, however, a young doctor, fresh from the learned faculty, arrived in the town and installed himself close by the bone-setter. It was not long before our *confrères* found out that his diplomas were of little use in competition with his rival. One day he was called to see the blacksmith, who was very ill, and, after a proper examination, he prescribed for him according to the rules of his art and said that he would return the following day. That same evening, however, the bone-setter stepped in and told the patient that if he took what had been ordered for him he would be dead before the moon set a second time. Needless to say, the bottles were thrown out, and the charms of the medicine-man substituted. The blacksmith got well. Exposed to constant affronts and a thousand-and-one annoyances, our unfortunate doctor determined to abandon the struggle, and returned to Paris with only five shillings in his pocket. He died a few years ago, leaving a colossal fortune, a brilliant renown, and a celebrated name, and a statue has been erected to him opposite the hospital where he worked the greater part of his life in the interest of humanity and science. His name was RICOED."

PLAGUE IN BOMBAY.

THE number of deaths in Bombay from plague for the week ending 22nd March were 1,359; for the week ending 29th March, 978; and for the week ending 5th April 799.

From this it appears that a considerable reduction has set in since the 22nd of March, this is by some attributed to the heat of the weather.

A sudden fall in the total mortality for Bombay occurred, on the 27th March; for the previous 7 days it had been over 800, but on the 27th it dropped to 254, and continued to fall to the end of the month. The following are the mortal statistics for the week ending 5th April.

Kurrachee, 8 cases and no deaths; and Poona, 7 cases and 8 deaths. In the districts Kaira had no cases and 1 death; Broach, 1 case and 1 death; Surat, 75 cases and 63 deaths; Thana, 84 cases and 48 deaths; Khandesh, 1 case and 1 death; Nasik, 14 cases and 17 deaths; Poona, 7 cases and 6 deaths; Satara, 36 cases and 34 deaths; Sholapoor, 11 cases and 8 deaths; Kolaba, 84 cases and 45 deaths; Ratnagiri, 43 cases and 37 deaths; and Belgaum,

45 cases and 56 deaths. In the Territories, Baroda had 175 cases and 168 deaths; Kathiawar, 5 cases and 3 deaths; Kolhapur, 30 cases and 55 deaths; Ootch, 9 cases and 9 deaths and Sore Kantha, 15 cases and 13 deaths; Palanpur, 19 cases and 16 deaths; Sachin, 6 cases and five deaths; Janjira two cases and one death; Akalkot, 8 cases and 3 deaths; Anand, 1 case and 1 death; Bhor, 8 cases and one death; total, 1,557 cases and 1,346 deaths. The deaths up to date have numbered 82,581.

CONDEMNATION OF THE OFFICE OF CORONER

SAYS the *Journal of the American Medical Association*:—"The following is a part of a recent presentment of grandjury of the County of Kings, New York: 'We have also investigated the methods in vogue in the office of the coroners. It is proper, however, to say that we have not taken up the methods in vogue under the present coroners, but only for the time prior to their taking office. We recommend to the legislature of the State that the office of coroner be abolished. We believe, from our investigation, that the office is useless, that it has no practical effect in the ferreting out of crime; that the methods in vogue in that office during the time of our investigation are open to the most severe censure; the manner of conducting the business was inefficient, and the powers of the coroners were delegated to subordinates whose chief functions seem to be to get rid of the business and collect the fees incident to the office for their chiefs. We believe that the continuance of the coroner's office in its present shape, as the law now stands, will lead to further abuses; that the law governing the rights, duties and obligations of coroners is not clear nor specific; that the very fact that various interpretations as to the rights and duties of the coroners may be put upon the law by those who should be familiar with it, will lead to abuses which only the entire abolition of the office can wipe out'"

CHEMICAL EXAMINER AND MEDICAL EDITOR.

SURGEON-CAPTAIN BEDFORD, Editor-in-Chief of the *Indian Medical Gazette* and Chemical Examiner to the Government of Bengal, has, we regret to learn, been compelled to go away on twelve months' furlough owing to ill health, so that the disputation about the Chemical Examiner to Government holding an editorial position is at an end. One thing we learn on good authority, and it is this, that no Chemical Examiner will ever again be permitted to place himself in so compromising a position.

We wish Dr. BEDFORD a splendid time at home and trust he will come back to his labors in thoroughly renewed health and strength. Few officers could be found so well-fitted to hold the office of Chemical Examiner as Dr. BEDFORD. In the meanwhile Surgeon-Captain MAYNARD, M.B., I. M. S., acts as Editor-in-Chief of the *Gazette*. Dr. MAYNARD holds a Resident Surgeoncy in the Calcutta European General Hospital. We seriously question the competency of Dr. MAYNARD to perform these dual offices, and we protest in the name of the public, against a badly officered Hospital allowing a member of its staff, detracting from the due and proper fulfilment of his official duties by handicapping himself with private contracts.

DR. MANSON AND THE MOSQUITO THEORY OF MALARIA.

We are quite accustomed to startling statements from Dr. MANSON; he is an enthusiast, and when he gets a hobby, is inclined to ride it a little too hard. He has saddled the mosquito with the *Plasmodium* malarie, to his own satisfaction at any rate, and now desires to bridle it with the malarial parasite. The mosquito seems to be his *bête noir*;

and his particular province to prove to a sceptical world that the divine wisdom has some object in view in the creation of this pest.

Dr. MANSON should reflect upon the old fable and remember that it is possible to put too many things on one back.

His latest utterance on this subject, made before the Epidemiological Society in London on the 18th February last, exceeds for extravagance anything we have previously heard from him. As reported in the *British Medical Journal*, he said that he had seen the *plasmodium* in the stomachs and tissues of the mosquito. To see it in the stomachs may be no difficult task, and means nothing; but in the tissues: that is different.

We cannot believe that Dr. MANSON was in earnest, we are rather inclined to think he must have been led away in the heat of controversy, if not, we should like to hear something more of these visions.

A SHORT WAY WITH HYPOSPADIAS.

THE *British Medical Journal* says:—"MR. GREEN, of Ripon, in a recent issue of the *Quarterly Medical Journal*, narrates a case of extreme hypospadias in a patient, aged 24, who had always passed as a woman. He had been living in domestic service as a housemaid when he suffered from symptoms attributed to the absence of menstruation. Careful examination showed a condition of extreme hypospadias. The scrotum was split into two halves, each containing a testis. No prostate could be felt *per rectum*, and the development of the genital apparatus appeared to have been arrested *in utero* about the third month. 'The question,' says Mr. GREEN, 'now arose as to what should be done, and as the patient in mind and habit is more a woman than a man, and it is illegal for him to remain as he is in female attire, he expressed a desire to have the testicles removed and continue a woman; and it seems to me that this is the best solution of the difficulty.' Mr. GREEN therefore admitted the patient, at his own urgent request, into the Ripon Cottage Hospital, and removed both the testicles. He made a good recovery, and, being now unsexed, has returned to domestic service as a housemaid. Subsequent microscopic examination of the testes showed them to be in every respect normal and active organs."

AN ABUSE OF MEDICAL CHARITY.

SAYS the *New York Medical Journal*:—"Last winter a man presented himself at the New York Ophthalmic Hospital and asked that an operation for cataract be performed, stating that he was very poor. The hospital is partly supported by charity. In view of the man's statement, that he was unable to pay much, the physician in charge reduced the usual \$15 per week to \$5 per week for board and attendance. The man was admitted and stayed several weeks. It was then learned that he was senior member of a large wholesale grocery firm, and was worth about \$150,000. The hospital, therefore, presented a bill for \$200, the full rates; the man refused to pay; the hospital sued, and received a verdict for the amount. Such vigorous treatment applied to a few of the many similar cases constantly occurring would have a beneficial influence upon the community."

SCOTTISH UNIVERSITIES AND THEIR GRADUATES.

SAYS the *Lancet*:—"The movement in favor of obtaining for the authorities of the Scottish universities the power to exercise discipline over their respective graduates is at last taking definite shape. The most active steps in this direction have been promoted by the University of Glasgow, and at a recent meeting of the University Court it was reported

that the other three universities had forwarded the names of their representatives appointed to sit on a joint commission in connection with this question and Sir WILLIAM GAIARDNER was authorized to take the steps necessary to call this committee together. If the aim of the committee is attained, Scottish medical graduates will be brought into the same relation to their degree-granting bodies as at present obtains between Licentiates in medicine and surgery and the corporations from which they hold their Licences. Thus graduates equally with Licentiates will be liable to be censured or to have their names removed from the University List for proved misconduct, whilst at present the holder of a university degree retains and can use his degree even though his name has been removed from the Register by the General Medical Council.

A PARISIAN HOSPITAL A HUNDRED YEARS AGO.

M. BROUARDEL (*Annales D'Hygiène Publique* February 1898) reminds us of the conditions of hospitals in Paris one hundred years ago.

There were two sorts of beds: the large and the small. The former were the most numerous, each of these was occupied by several patients, four or sometimes six, so closely were they packed that they could not move in the space allotted to them.

When the number of admissions was excessive, the bed was covered with a sort of roof on which five or six fresh patients were placed.

In these beds where four and six patients were put, it was remarked "that the peculiar heat of each disease was lost in the common heat of all, and contagious cases such as small-pox, were put into the same rooms, and even into the same beds with people suffering from non-infectious diseases."

M. BROUARDEL remarks: "I do not believe that even the powerful imagination of DANTE in the Divine Comedy has evolved torments equal to those which under the guise of pity were inflicted upon these unhappy people."

SEGREGATION AND ISOLATION.

THE following are the new rules of the Bombay Government regarding segregation and isolation:—

It will be seen that its views on these subjects have been very much modified.

(1). Persons are only to be compulsorily removed by order of a plague authority to a health or segregation camp when their house is known to be infected with plague, and when they are unable to satisfy the plague authority that they will remain under observation in a sufficiently isolated and convenient place.

(2). Voluntary removal to a health camp or other place of safety should be encouraged by all means possible.

(3). If a plague case can be suitably treated and isolated in a house of sanitary situation free from the danger of spreading infection, the patient may be allowed to remain, provided that the other occupants (save the immediate attendants) remove themselves elsewhere as above stated.

(4). In the case of all removals sufficient time should be allowed under proper observation for the making of the necessary arrangements.

A NEW HEALTH SOCIETY.

A CORRESPONDENT writes to the Bombay papers suggesting the formation of a Health Society, having for its object the promotion of sanitary reform in that city. The Association should, he says, make it its business—(1). To enquire into individual complaints as regards sanitary defects and to bring the same to the notice of the responsible authorities. (2). To consider practical suggestions for improvement, and to recommend the same for adoption. (3). To

institute legal proceedings in the case of offences against sanitary laws. (4). To arrange for lectures on hygienic subjects, and to educate the people, as far as possible, by the distribution of vernacular tracts dealing with the elements of sanitary science. (5). To generally promote the sanitary welfare of the city, and last, but not least (6) to prepare the way for the establishment of sanitary institutes for India.

KIPLING'S ESTIMATE OF AMERICAN AND OTHER PRACTITIONERS.

SAYS the *Medical News*:—"RUDYARD KIPPLING, the poet novelist, in an after-dinner speech at a banquet given in London to Sir WILLIAM GOWERS not long since, paid a graceful tribute to the heroism of the medical fraternity. He had mixed with doctors, he said, the world over, and had seen them going to certain death with no hope of reward. He had seen them handling cholera and smallpox, and, when dying therefrom, telegraphing for a substitute. He had seen them, in America, manage a practice twenty miles in each direction, driving horses through eight feet of snow to attend an operation ten miles away, digging their horses out of the snow and then proceeding on their way. Mr. KIPPLING declared that it was one of the proudest things of his life to have been associated with 'real fighting men of this class.'"

THE WORK OF LADY DUFFERIN'S FUND IN INDIA.

THE Marchioness of Dufferin and Ava has just issued her report for last year of the United Kingdom Branch of the work done by the great fund bearing her own name for supplying medical aid to women in India. The growth of the movement is really astonishing, for Lady Dufferin states that in the twelve months under review, no less than 1,327,000 women received attention either in hospitals or their own homes from lady doctors. There are now 103 hospitals and dispensaries under the charge of a staff of twenty-eight ladies whose names are on the English Medical Register, seventy lady Assistant Surgeons, and seventy Hospital Assistants, most of whom are native women educated at the Indian universities. At the present moment there are 240 ladies studying in these Medical Colleges, among them being high-caste Hindus, Mahomedans, Parsees, Karens and Burmese.

A BRITISH INDIAN VETERAN.

DEPUTY-SURGEON-GENERAL EDMUND MACGHEATH, who died at Upper Norwood, London, on 8th March, passed the greater portion of his service with the 8th Hussars and the Royal Artillery. He was specially thanked for his services during the cholera epidemic in the Punjab in 1862, when the Inspector-General wrote that he desired to express "the high sense of approbation entertained both by His Royal Highness the Duke of Cambridge and His Excellency the Commander-in-Chief in this country of the unwearied attention, skill, and devotion which you exhibited in the performance of your arduous duties during that trying period." During the Egyptian campaign he was principal medical officer at Alexandria and was again thanked for his services, and received the medal, Khedive star, and the Third Class of Medjidieh. Deputy-Surgeon-General MACGHEATH leaves a widow and a son, who is in practice at Reigate.

NORTHUMB.

SAYS the *Canadian Druggist*:—"Dr. MORTON SMALE, writing to the *LANCET*, asks if it is not possible to bring pressure to bear upon the Legislature in regard to suppressing secret medicines, the desirability of which all members of the medical profession, he says, are agreed upon. Mention is

made of the suggestion thrown out by Sir WILLIAM BROADBENT when speaking to the students of St. Mary's Hospital in 1896, and Dr. SALKIN thinks with him that if the ingredients and exact quantities of the drugs were printed on the bottle, it would explode a good deal of the mystery at present enveloping these remedies. The Board of Trade should be approached on the subject by representatives of all medical corporations and societies, he says, and urged by deliberate consultation to arrive at some remedy for the existing state of affairs."

THE IMPERIAL ANGLO-INDIAN ASSOCIATION.

SAYS the *Engländer* :—"The first meeting of the Directors of the newly-formed Imperial Anglo-Indian Association was held on Monday evening, when the new Memorandum of Association and the Rules framed under it were adopted after careful consideration. The administrative part of the Association will now be under the control of Directors who have been invested with real power to work for those whom they represent. Thus, every Director will bring with him one hundred members. There are to be not less than fifty Directors, and when each has brought in his one hundred members, there will be five thousand members added to the Association in Calcutta alone. Then the new designation, Memorandum of Association and Rules will be adopted by the Sister Presidencies, and if they work steadily, there are expected soon to be over fifty thousand members in India. Each Director undertakes to bring in one hundred members in order to make himself eligible for election. A Council will be annually elected from among these Directors, consisting of one President, four Vice-Presidents, and twelve members; and this Council will administer the Association. There was also a proposal to form a Grand National Council for all India to be presided over by an officer to be styled the President-General; but this matter was held over for further consideration."

THE F. R. C. S. IN IRELAND.

We quote from the *Lancet* :—"The most important examination for the Fellowship of this College that has been held for years terminated by conference on 28th February. There were no less than twenty-seven candidates, eleven of the junior grade—that is, of less than ten years' standing—and sixteen of the senior rank. Of the junior four were rejected while one retired. At the senior and final examination ten failed, while one lady, four well-known hospital surgeons, and one gentleman from New Zealand passed. Dr. ROBERT WOODS, F.R.C.S. Irel., has resigned the position of Secretary to the Council of the College, but will discharge the duties of the office until the date of the new election on the first Monday in June."

HOUSES OF ILL-FAME AS MASSAGE ESTABLISHMENTS.

SAYS the *N. Y. Medical Record* :—"This form of deception and vice has been carried on in London for a number of years. It is one of the most subtle, insinuating evils with which the detectives and police of that city have had to deal. The first suspicion that it had invaded America and endeavoured to establish itself there was aroused by the recent account of the case of a young girl from Buffalo, N. Y., who was lured from her home by an advertisement purporting to come from a massage establishment in New York City. On account of what she saw and the insults offered her in the house, she fled in terror, and later became insane."

BURGLING AN ABSCESS. A NEW OPERATION.

SAYS the *Medical and Surgical Reporter* :—"There are few things without their uses in this world, and we now rejoice to find that the burglar has his uses as an involuntary agent in a surgical operation. Professor BROUARDEL, in a recent lecture, related the following case: A man had a pharyngeal abscess so deeply seated that his medical attendant was afraid to meddle with it. One night a burglar broke into the house, and on the sick man calling for help tried to throttle him. The abscess burst, deluging the burglar with pus and causing him to make a rapid exit. His intended victim, on the other hand, experienced instant relief, and made a rapid recovery."

MADRAS "FEVERS."

WE note with satisfaction that our remarks on the great mortality in Madras town from "fevers," and our dissent from the explanation offered by the Sanitary Commissioner, are receiving some attention.

Our articles on the subject published in our issues of 1st and 15th February have appeared in extenso in the *Eastern Guardian* which remarks—But for the counteractive of the sea breeze which is considered an effectual febrifuge, Madras would be a hopelessly fever-stricken city. The mortuary register of last week exhibits a high number of deaths from fever, viz., 118, while small-pox and tonsillitis are greatly on the increase."

NEW MEMBERS OF THE INDIAN MEDICAL ASSOCIATION.

THE following have joined the Association since our last publication :—

Edward Peacock, Assistant Surgeon, Station Hospital, Belgaum.

James Mackey, Assistant Surgeon, Fyzabad.

Lionel George Scott, Assistant Surgeon, R.I.M.S., "Lawrence," Bushite.

Nara Singha Row, Rayagadia, Vizag District.

G. Nahi Khan, C.M.S., Jail and Police Hospital, Secunderabad.

NEW MEMBERS OF THE INDIAN MEDICAL ASSOCIATION PROVIDENT FUND.

THE following have joined the Fund since our last publication :—

M. Iyasawmy Pillay, C.M.S., Dowlahswaram.

Syed Abdul Kader Sahab, C.M.S., Tharawaddy, Burma.

Angus Robertson, Assistant Surgeon, Station Hospital, Ferozepore.

Tharst Husain Khan Sahib, C.M.S., 16th Regiment B. I., Malakaud.

James Mackey, Assistant Surgeon, Station Hospital, Fyzabad.

NEW CALCUTTA.

MR. HUGHES, the Engineer to the Corporation, has published a lucid statement of his ideas as to the reconstruction of Calcutta. He proposes, by making seven new streets, to divide Calcutta into seventy rectangular blocks, each of which will be about a quarter of a mile square. There will be seven and a quarter miles of east and west streets, and nine miles of north and south streets. The Local Government will strengthen the hands of the Corporation to enable these improvements to be carried out. The scheme deals with a central railway station, tramway connection for the suburbs, and the removal of the Municipal railway from Circular Road.

DISCIPLINARY POWERS OF UNIVERSITIES.

SAYS the *British Medical Journal*:—"At a Convocation of the University of Durham, held on 1st February, it was proposed to revoke the degrees of a graduate in medicine and surgery, in accordance with the penal powers of the new charter of the University. At the last meeting of the Edinburgh University Court, it was agreed to appoint Lord STORMONT-DARLING, Sir WILLIAM TURNER, and Dr. HENRY WATSON as the Court's representatives on the Joint-Committee of the Scottish Universities, to consider the question of acquiring penal and disciplinary powers over graduates guilty of a criminal or other offence."

A MARRIAGE EXAMINING BOARD.

SAYS the *British Medical Journal*:—"A reformer in the Ohio Legislature has introduced a Bill requiring persons applying for marriage licences to pass a medical examination. The Bill forbids the issue of a licence to any person suffering from dipsomania, insanity, or tuberculosis. It provides for a marriage examining Board of three physicians in each county. A measure of this kind has been advocated by many reformers of society from Sir THOMAS MORE down to our own day, but if science is strong, human nature is stronger. It is pretty certain that love which laughs at locksmiths will not show more respect for medical certificates."

THE BIBLICAL MYRRH.

THE London *Chemist and Druggist* says—This was not myrrh, as we know it, at all. The error arose from the similarity of the Hebrew word and the Arabian name for myrrh, *murr*. The Biblical word should have been translated *balsam*, which is made plain by the fact that it was a highly odorous liquid, while myrrh, or the myrris (there are several of them) that we know anything about are solids, possessing an odour it is true, but scarcely aromatic. The "balsam" of the Jews is the exudation of a palm known as *Commiphora opobalsamum*.

PLAGUE IN THE PUNJAB.

THE plague in the Punjab is assuming a very serious look, it is gradually approaching Lahore. No efforts are being spared to keep it in check, and the following very large staff is employed for this purpose.

Three District Superintendents of Police, five Assistant District Superintendents of Police, 4 Inspectors, 24 Deputy Inspectors, 171 Sergeants, and 1,888 Constables are actively engaged on plague work, being a total of 2,046 of all ranks. Besides these, two officers and 968 rank and file are under orders, which bring the total up to 8,000.

MR. GLADSTONE'S ILLNESS.

THE *Lancet* of the 26th March says—"We regret to learn that Mr. GLADSTONE's case has entered on a new phase, which has made surgical advice necessary. This can scarcely be interpreted in any other way than that there is a serious cause for the symptoms from which he has suffered during the past nine months. At his great age the gravity of any surgical ailment is apparent, and the exhaustion consequent on prolonged and severe neuralgia is in itself an unfavorable feature. Mr. GLADSTONE's vitality, however, is wonderful, and his general health remains good."

ATTEMPT AT POISONING A PLAGUE OFFICER.

DR. BRITTO, Medical Officer in charge of a plague district reports what, he believes, was an attempt to poison him. He says, that an Inspector went to an earthenware vessel, in which Dr. BRITTO kept drinking-water for his personal use for the purpose of quenching his thirst. No sooner had he tasted it, then it was reported to Dr. BRITTO, that it had a peculiar flavor. A test was applied, and perchloride of

mercury was found. The Inspector was promptly removed to hospital, where he recovered after the usual treatment.

WHAT A MAN EATS IN A LIFETIME.

It is computed, by a contributor of inquiring mind to an English journal, that a healthy man with a good appetite and average drinking-capacity assimilates into his system during seventy years ninety-six and one-half tons of material, solid and liquid; or, putting it in another way, and assuming his weight to be twelve stones, he consumes over twelve hundred and eighty times his own weight of nourishment in the course of a lifetime.

IMPORTANT NOTICE TO DEFAULTING SUBSCRIBERS.

OUR Manager regrets being compelled to notify BAD PAYERS by a new method. He is tired of old methods, as BAD PAYERS thrive on secrecy. He notifies that subscribers to the *Record*, who have not paid their dues for over three years, will have their amounts notified to them through the *Record* in a regular list. He gives one full month's notice of this threat, which will be put into execution on the 1st May next.

SHORT ITEMS.

The four extra pensions of £100 each, available for 1898-99, have been given to Brigade-Surgeon-Lieutenant-Colonels the Hon. Sir A. S. Lethbridge and D. D. Cunningham, I. M. S., of the Bengal Command, to Brigade-Surgeon-Lieutenant-Colonel F. H. Blenkinsop of the Madras Command, and to Brigade-Surgeon-Lieutenant-Colonel J. Arnott of the Bombay Command. They are all on leave in England, and will retire in the course of the current year.

We find from the *Punjab Gazette*, Medical Department Notification No. 1022, dated 22nd March 1898, that third class Hospital Assistant No. 489 Pertab Singh, at present in charge of the Indri Dispensary, Karnal District, is permitted to change his name to Heinrich Burdett Franklin. We look upon this as a political mistake. Indians should stick to their Indian names. To do otherwise is to inflict a socio-political wrong on two communities.

As an instance of the value set upon their service in connection with the plague demand for female doctors, it may be mentioned that a native female Hospital Assistant, whose ordinary pay is Rs. 40 per mensem with free quarters, asks for Rs. 200 per mensem with advance money and free house. For this sum it is possible to obtain trained European female medical aid.

Dr. Froence, the Health Officer of Dumaon, died of plague at the plague hospital at Marward at 2 P.M. on Saturday. He had inoculated a number of persons with Professor Haffkine's serum at the bidding of His Excellency, but he never submitted himself to inoculation, though he fearlessly treated plague patients. He was 38 years old at the time of his death.

Says the *Statesman*:—"Dr. Wallace's stirring speech on the Anglo-Indian Cause, at the Annual Meeting of the Anglo-Indian Association on the 26th March, at Calcutta, has been reproduced in most of the daily papers of the country and commented on in the most appreciative manner. It has certainly roused the whole country, for two of the Branch Associations have expressed their congratulations to Dr. Wallace telegraphically."

We are glad to note that the charge of Inspecting Medical Officer at Chowra Station, on the East Indian Railway, has been given over to a native Assistant Surgeon, Bahu Samuka Mohan Mukhopadhyaya.

One of the blue editions of the prototype of *Mitbourne* has been lost. On the death of the City Coroner, it was expected that the Government would follow the usual custom of appointing another medical man to the position; but the Commission exhibited no particular hasty of action in the matter until too late, and so the office went into the hands of a layman.

The *British Medical Journal* announces the death of Dr. Charles West, which took place on 19th, March at the age of 81. Dr. West's name is known to the whole medical world by his writings on children's diseases, a department of medicine in which he was a pioneer, and for a long time the leader, in this country. They hope to publish an account of his career in an early issue.

Surgeon-Lieutenant-Colonel Fawcett, Civil Surgeon, Secunderabad, takes eighteen months' furlough, at the end of which he retires. Surgeon-Lieutenant-Colonel Little, Principal Medical Officer, Hyderabad Contingent, takes his place. Dr. Fawcett has been in Hyderabad since 1890 and was exceedingly popular. His departure is much regretted.

Dr. Lloyd-Jones has been temporarily appointed Medical Officer and Superintendent of Maternity till the end of the season, when Dr. Baker, who is now on leave in England, will take charge in October next. The present Superintendent, Mr. Edwards, of the Civil Service, goes back to his former appointment.

A series of experiments, made by Mr. E. H. Hankin Chemical Examiner and Bacteriologist, Agra, in the spring of last year, have led to the supposition that wheat and flour are not susceptible to infection by the bubonic plague microbes.

It is a happy augury for the healthier Bombay of the future, that the week in which the City Improvement Act has been passed into law, has seen a very marked decline in the virulence of the plague epidemic.

Mr. Frederick Treves, F.R.C.S., recently removed the whole of that part of the bowel below the transverse colon, together with the anus in a case of idiopathic dilatation of the colon in a child. The patient made a good recovery.

The Columbus (Indiana) Health Board has issued an order requiring the pupils of the public schools to provide themselves with individual drinking-cups. The Board is also in favor of individual communion services.

Two Russian medical men have been deputed to the Punjab by their Government to study the plague and its development. Their names are Werner and Kaschkadamfor. They have been at Lahore for some days.

The residents in Dhurrumtollah Street are about to ask the Municipality to change its name to Dufferin Street, as it is a locality largely occupied by Europeans, and it is thought it should have a European name.

Dr. Simpson, late Health Officer of Calcutta and Dr. James Cantlie, formerly of Hongkong, are appointed joint editors of a new medical journal, entitled *The Journal of Tropical Medicine*. Dr. Cantlie graduated at Aberdeen.

The Allahabad University has set the example of conferring an examinership on a lady. The Lucknow *devoante* learns that Mrs. Jennings has been appointed Examiner in History in the current intermediate examination.

A great many letters have of late been received by Professor Schenk, of Vienna, from mothers and would-be mothers, asking him to tell them how to bring forth sons instead of daughters.

During Sir Alexander Mackenzie's regime, Dr. Spiers Banking, "Inspector of Oriental Languages," was permitted private medical practice among railway employees. We wonder if this "perquisite" will be continued.

Dr. John Morton writes:—"Mussorie is in a great state of excitement over the Anglo-Indian question. Shall we form a branch here. It will be a very powerful one. We are 4'000 strong!" Of course friends, at once.

"The human race is divided into two classes," said Oliver Wendell Holmes—"those who go ahead and do something, and those who sit and inquire, 'why wasn't it done the other way?'"

The exploring needle is unreliable in finding small liver abscesses, and the use of the knife is recommended even though the needle fails to locate the abscess to which the symptoms point.

Dr. Langley, who came out to Madras recently in connection with the plague, and was attached to the General Hospital, has been transferred to Arkonam for plague duty.

Thos. A. Edison, Jr., believes that he has made a discovery which will result in a perfect electrical apparatus for reproducing human thoughts as they are evolved in the mind.

Surgeon-Captain D. Simpson, Surgeon of the 2nd District, Madras, has gone to Coimbatore. Surgeon-Captain Giffard will succeed him in the 2nd District.

Dr. John P. Maynard, well known as the introducer of collodion into the practice of surgery, died at Dedham, Mass., on Friday, 26th, aged 72 years.

Mr. F. G. Wigley, Assistant Secretary to the Government of Bengal in the Legislative Department, is appointed to be Coroner of Calcutta, with effect from the 13th instant.

Surgeon-Captain C. H. Bedford, late Officiating Chemical Examiner and Professor of Chemistry in the Medical College, Calcutta, takes leave for twelve months.

Dr. D. A. Choksi, Civil Surgeon, Bangalore, has been deputed by the Durbar to Bombay for the purpose of studying Professor Haffkine's method of inoculation.

We are glad to see that Mr. N. B. Darabeseth, M.B.C.S., M.B., C.M., has passed the necessary examinations and has been admitted a Diplomate in Public Health.

A month ago, a little Eurasian girl, named Iris Thomas, was bitten by a rabid dog, and symptoms of hydrophobia set in, she died in Bombay on the 7th instant.

Miss Florence Hope Dissent, M.D., late Surgeon to the Ulwar State Zenana Hospital, is to marry Mr. J. F. E. Barnes of Lahore on the 28th April 1898.

Dr. Murray, Civil Surgeon, Howrah, officiates as Professor of Surgery, Medical College, Calcutta, *vice* Dr. O'Brien, proceeding home on seven months' furlough.

When the cervix is as hard as the tip of one's nose, pregnancy presumably does not exist, but if it is as soft as one's lips, the existence of pregnancy is probable.—GOODALL.

Surgeon-Captain G. Capel Hall, I. M. S., has been permitted to retire from the service from the 13th of March.

Dr. Simpson, late Health Officer of Calcutta, has been appointed Professor of Hygiene at King's College, London.

We regret to announce the death of Brigade-Surgeon G. M. Govan, M.D., Bengal Retired List, at Almora, on the 9th.

VITAL STATISTICS OF CALCUTTA.

Statement of Deaths from Principal Diseases in Calcutta during the week ending 10th March to the 6th April 1898.

Week ending.	Cholera.	Small-pox.	Fever.	Bowel complaints.	Also other diseases.	Total.	Total population, according to the census of 1891.	Ratio per 1,000 of population per annum.
19th March	17	3	160	42	286	458	6,81,560	35.0
26th March	85	3	147	55	219	459	...	35.1
2nd April	43	6	156	51	201	457	...	34.1
9th April	87	2	141	48	176	404	...	30.9

Current Medical Literature.

MEDICINE.

Treatment of Locomotor Ataxia.

LANGDON strongly advocated simple hygiene with a sinusoidal current of high potential, rapid alternation (480 to 1,920 per second) and comparatively small quantity per foot-plate and neck-electrode for 5 to 15 minutes on alternate days for six weeks, as the best mode of treating locomotor ataxia, which he looks upon not as a sclerosis, but a periphero-central degeneration of sensory neuron endings, and urges that early diagnosis (earlier the better) and proper treatment will distinctly benefit, if not practically cure, the patient by (1) limiting the degenerative process to a small number of neurons, (2) reproducing certain nerve endings, and (3) promoting increase on functional power in endings still competent though lowered in vitality and function. While antisyphilitic treatment is uncalled for, alcohol and opiates are decidedly pernicious and the old fads of giving mercury and potassium iodide are senseless. Faradism is useless, galvanism useful in a large proportion of cases. The lightning pains may be relieved by 2 to 4 grain doses of aluminium chloride, and the most valuable drugs are phosphorus, iron and codliver oil with strychnine; but liberal diet (meats, fats, milk, water *ad lib* and fruits, with very little saccharine or starchy foods) hygiene (warm clothes and climate) and rest are the main factors to successful treatment where digestion, assimilation and elimination (especially of auto-toxins) must be promoted.—*Cincinnati Lancet Clinic*.

Clinical Value of the Widal Test.

THERE are fashions in medicine as there are in costumes. Experience has shown that the value of EHRICH's diaro-test for typhoid was not nearly so great as was predicted, and the WIDAL test (*Lancet*) seems likely to secure a similar verdict, since Dr. W. GILMAN THOMPSON, of New York, who has analysed 503 cases of fever, thinks (*Medical News*) that the WIDAL test, though very instructive from a bacteriological point of view, is of little practical diagnostic value to the clinician, who in 75 to 80 per cent. of the cases, needs no confirmatory test beyond the plain history and symptoms of typhoid fever, while the remainder of the cases in which such a test would be invaluable if it were exclusively accurate are chiefly (1) the very early stages or (2) various atypical forms of enteric fever, (3) obscure sepsis, (4) severe or protracted malarial remittent fever and some cases of (5) typhus fever or of (6) acute military tuberculosis. Dr. THOMPSON (*Lancet*) hopes that further possible improvement in technique may place the WIDAL test upon a firmer practical basis than can at present be claimed for it, since

just now it yields (1) a margin of error of 11 to 12 per cent. on either side of the normal line in cases in which it fails where it ought to succeed, and succeeds where it ought to fail, which 23 per cent. of possible error unfortunately (2) includes just those very cases in which there is the greatest doubt from the purely clinical side, and (3) this test, which is confirmatory in connection with appropriate symptoms, is misleading if positive reliance be placed upon it alone; since as a genuine diagnostic agent it (4) has about the value of the diaro-reaction in typhoid urine or the study of leucocytosis in pneumonia.

Habitual Constipation.

THOUGH he does not altogether set aside the theories of intestinal intoxication and doubtful prognosis as regards complete recovery, EWALD says that diminished irritability of the intestinal nerves or defective development in the muscular coat of the intestine indicate one form of habitual constipation in which an hereditary factor is often present. He shows the relation of mental disturbance to constipation which exhibiting itself by general and local symptoms may be the result of (1) suppressing the desire to defecate (2) an abundant diet difficult to digest, deficient in water and too easily absorbed or of insufficient variety, (3) sedentary habits, (4) too active a life, (5) disturbances in the circulation (6) mechanical pressure, (7) pregnancy, (8) displacement of the bowel, (9) mental worry, and (10) adhesion of coils of intestine to each other or to some organ. He supports three lines of treatment. (1) *Dietetic* in which only food that increases peristalsis should be eaten, (2) *Physico-mechanical* consisting of clysters aided by massage, and (3) *Medicinal*, in which saline purgatives and the mineral waters of German spas are well to the fore, and purgation should be mild or powerful in accordance to the symptoms present, but it should not be made a daily practice of. Sometimes sedative and anti-spasmodic remedies are needed, where constipation is of the spastic type.—*Par. Med. Jour.*

Reflex Neuroses of Nasal Origin.

AT a meeting of the Netherland Society of Laryngology, Rhinology, and Otology, Dr. MOLL, of Arnheim, reviewed the history of nervous reflexes and cautions against adopting extreme opinions which attribute to them, at one time, too great and, then, again, too small a role. He described a case of very serious disorder of deglutition in a man, aged 60 years, and which completely disappeared after ablation of a spur of the septum. The patient, who for a year could only swallow liquids, gained the power of taking solids. In another similar case the immediate effect of the operation was equally satisfactory, but the final result was less favorable.—*Med. Bulletin*.

CONJUNCTIVITIS SUMMARY NOTES.

BY G. L. GARDNER, M.D., F.R.C.S.

Medical College, Lahore.

On the Treatment of the more Common Eye Affections.

In the *Edinburgh Medical Journal* for October 1897, Mr. GEORGE HUNTER begins a series of practical papers under the above title. Speaking of the treatment of conjunctivitis, the writer tells us, that in the acute stage, the principal point to attend to is not to interfere too energetically. There is, as I have already hinted, a danger in doing too much. All that is necessary in most cases is to freely remove the secretion during the day, and to prevent its too great retention within the conjunctival sac at night. Even those who are sufficiently alive to the disadvantages of an active treatment with astringent lotions, rarely seem to take care that the more suitable, mildly antiseptic or other bland lotion which they employ is so used as to properly irrigate the inflamed conjunctival surface. An efficient removal of discharge is not got by merely squeezing a little lotion from a sponge or piece of cotton-wool into the lower conjunctival sac, or by using an eye-bath. In very many cases, however, the tendency to a speedy return to the normal in the absence of irritative treatment is so great, that this is not of much consequence. It certainly, however, is a better plan to irrigate properly. This may be done by allowing a pint or more of the lotion (preferably a 2 per cent. solution of boric acid at a temperature of 90° to 98° F.) to stream by gravitation over the whole surface of the conjunctiva three or four times daily. For this purpose the vessel containing the liquid may be held 10 or 12 inches above the head, allowed to run through india-rubber tubing, to the end of which is fixed a flattened glass nozzle.

The nozzle can be readily inserted below the upper and lower lids without touching the cornea. It is usually best to begin by everting the upper lid, and, after irrigating its tarsal surface, to insert the glass nozzle behind the upper margin of the tarsus, so as to get at the retro-tarsal fold.

In the more severe and protracted cases, a daily direct application to the conjunctival surface, with a camel's-hair brush, of a strong antiseptic solution is useful. The most suitable are strong (fully saturated) chlorine water and nitrate of silver in a 2 per cent. solution. Though not always so readily got, the first is the better, and when painted over the palpebral conjunctiva causes no pain to speak of. Corrosive sublimate solutions should be avoided; they are more irritating and far less penetrating.

The margins of the lids should in all cases be kept smeared with some bland ointment. Fresh lard or fresh butter do very well. Vaseline is not always pure, and may cause irritation. Boracic ointment (boracic acid 3ss. almond oil 80 mm., and superacetat ointment 3ss.) is what I generally use.

The questions of light, and of the use of the eyes to reading etc., remain to be considered. With all inflammations of the eye itself, as well as of the conjunctiva, there is more or less photophobia, or dread of light. It does not follow, however, that the light is actually hurtful. The active rays are known to cause direct irritation of the conjunctiva, which may, indeed, as in snow-blindness and electric-light ophthalmia, be so great as to cause violent inflammation. On the other hand, the same rays have been shown to exert a powerful bactericidal effect. It is a very common treatment to keep patients suffering from conjunctivitis in a dark room. Often this is continued for weeks; and although the discomfort which light causes is thus avoided, there is little doubt that this treatment tends to prolong the inflammation rather than to cut it short. The patient, too, soon has his retina so adapted for the dark that even a little increase of light is painful, just as one may experience a degree of dazzle from the light of a match struck at night.

The light of an ordinary room in the daytime, when the sun's rays are not passing directly into it so as to be unpleasant to anyone else, has not any bad effect on a conjunctivitis. On the other hand, the use of dark glasses outside in bright weather is advisable. They enable the patient to keep his eyes properly open, and subject him less to great distress from inflammation. The glasses should be neutral-tinted, and not blue. Blue glass, although absorbing light, transmits a larger proportion of the most irritating (ultra-violet) rays.

The open air, in the absence of rain or dust-storms, is unquestionably good. This is often not properly realised; it is

perhaps natural to suppose that there is an indication with a "cold in the eye" to remain in doors. Reading or writing should not be allowed.

In acute attacks it is seldom, however, that attempts at reading are persisted in. Why reading should be hurtful is not quite evident. It is certain, however, that it adds greatly to the discomfort caused by the conjunctivitis increasing at the same time the congestion.

This discomfort, besides, does not pass off on discontinuing reading, so does the discomfort first felt in ordinary light on coming from a darkened room.

Whether as the result of inappropriate treatment or otherwise, inflammation of the conjunctiva, instead of actively subsiding, may continue for an indefinite time as a chronic condition. "Chronic conjunctivitis" is met with in all degrees of severity, from what is little more than slight hyperæmia of the conjunctiva, to a greatly thickened, fleshy-looking, pus-secreting state of the membrane, with incrustation of the lid margin; and often, too, owing to deeper infiltration, the palpebral fibres of the orbicularis fail to keep the lower lid properly in contact with the eye. The swollen conjunctiva thus becomes everted, and the excretion of tears is interfered with. The overflowing tears cause excoriation of the skin, and the ectropion once set up becomes more and more marked as time goes on.

The everted conjunctiva besides being thickened, is, as the result of constant exposure to the air, also hardened, and may even be incrustated or covered by scales or scabs.

These very bad cases of chronic conjunctivitis are mostly met with in old people of uncleanly habits; they are not the cases one is most frequently called upon to treat. In all cases in which conjunctivitis has become chronic, the first points to be ascertained, before any line of treatment is begun, are the nature of the external surroundings and of the treatment which has already been adopted. Where the patient is constantly subjected to smoky or hot and close atmosphere, or to any evident source of irritation, such conditions should, as far as possible, be removed.

If he has been poulticing, or what comes to the same thing, keeping moist applications to the eye, or tying it up and allowing the bandage to become moistened by tears, or if strong astringent lotions have been used, such treatment should at once be discontinued.

It is generally well, too, to look to the state of the mucous membrane of the naso-pharynx, as a chronic catarrh in this situation is apt to keep up a conjunctivitis, even although it may not have been the principal cause in originating it. Still more important in this respect is the state of the tear sac. Inflammation of the mucous membrane lining the tear duct and sac is not infrequently complicated by conjunctivitis, which is then generally set up by inoculation from this source. On the other hand, even severe purulent primary inflammation of the conjunctiva seldom, if ever, spreads to the tear sac. A proper treatment of the inflammatory condition of the naso-pharynx is often useful, in addition to anything which may be undertaken for the more direct treatment of the conjunctivitis. But treatment of the sac for a co-existing blepharitis is an absolute necessity.

Without an improvement in this situation no treatment of the conjunctivitis alone can be of much avail.

In the least severe cases of chronic conjunctivitis, in which there is little or no thickening of the conjunctiva, and not much increase in the secretions, it is not generally necessary, if the precautions referred to as to surroundings be taken, to do anything very active. It is mainly in respect to their origin, namely, a preceding acute attack, that they differ at all from cases which I have described as conjunctival congestion. They should therefore be treated much in the same way. Change of air, especially to some dry, high-lying inland place, may be tried, and any existing error of refraction should be corrected. In addition, a weak astringent may sometimes be useful, such as solution of boric acid, tannic acid, myrrh, alum, cinchona, or ichthyol.

The following are prescriptions which may be recommended for this purpose:—

R	Resoline	℥iv.
	Aqua carui	℥viii.
R	Acidi tannici	℥v. vi. xii.
	Sodæ biboratis	℥i.
	Glycerini	℥vi.
	Aquam camphoræ an.	℥i.
R	Elixopæ myrris	℥i.
	Aqua destillata	℥i.

R	Aluminate	gr. x, xx.
	Aqua rose	℥i.
R	Extracti cinchonae flavae liquid	ss. ℥s.
	Acid hydrocyanici dilute	ss. ℥s.
	Glycerini	℥vi.
	Aquam destillatam ad.	℥i.
R	Ichthyol	℥i.
	Aqua sambuci	℥i.
	Aqua destillata, aa	℥vi.

In more severe cases, with thickening of the conjunctiva, swelling of the folds, and deeper infiltration as evidenced by slight ptosis, and with more or less distinct mucopurulent secretion, there is, I believe, nothing better than lead. A solution of the neutral subacetate of lead, in the strength of 10 grains to the ℥i of water, may be painted directly over the mucous surface of the everted lids once daily, and an irrigation of boric acid made twice or thrice daily, or a wash of the same lead salt in weaker solution (1—2 grs. to the ℥i) may be used about three or four times in the 24 hours. In the worst cases, painting with strong chlorine water or a 2 per cent. solution of nitrate of silver once daily, is useful in addition to the lead wash. Where there is ectropion of the lower lid, the lower canaliculus should be slit with a Weber's knife.

The scales must also be removed from the lid margin, and an ointment of iodoform and vasoline (1 to 6) smeared on the raw surface.

Owing to the frequency of folliculitis in young people, it often happens that the appearance of the conjunctiva presented in an ordinary, mucopurulent inflammation is such as to suggest some different and specific type of conjunctivitis. The overgrowth of adenoid tissue may be so marked a feature that the follicles appear as numerous papillae in the swollen and congested membrane.

When this is the case, it is not uncommon to hear the conjunctivitis spoken of as a follicular conjunctivitis.

It is not improbable that the same irritation which causes the conjunctiva to inflame may give rise to some further follicular enlargement, but as far as the inflammation goes, both in its causation and course, it is a simple conjunctivitis. The treatment should be in every way the same as that already described. Special care is, however, required in irrigating, as the presence of the many elevations makes it more difficult to thoroughly remove the secretions.

—O—

OBSTETRICS AND GYNÆCOLOGY.

Premonitory Symptoms of Puerperal Infection.

THE true rigor, local pains, and conspicuous pulse and temperature are known to all, and when combined, indicate more or less advanced infection, but these symptoms never come on suddenly, though certain milder types of infection now observed may represent sepsis modified by antiseptic agents; these milder types, however, will assuredly develop into deadly septic infection if neglected. But even the severest form is prececal for a day or two by distinct elevation of temperature and pulse, and by insomnia. An evening temperature of about 100° in the axilla, with a fall of about a degree in the morning, without a corresponding drop in a somewhat rapid pulse, is a distinctly suspicious symptom. The rise in the pulse often precedes the rise in the temperature; the observer must therefore make sure that acceleration of the heart's action is accounted for even in a patient who seems otherwise convalescent. Reaction after the fatigue of labor, hemorrhage, and emotions all send up the pulse. Insomnia is often observed in the earlier stages of infection, and distinct want of sleep without restlessness is usual for a day or two before bad septic symptoms. The lochia may remain free from odor in the premonitory stage of puerperal septicæmia, nor are the discharges always foetid when the disease is established.—*Med. Age.*

Tubal Gestation.

DUNSMAN has compiled a valuable monograph on this condition based upon operative experience and anatomical research. He feels sure that the most frequent cause of tubal gestation is gonorrhoea through the catarrhal salpingitis which that disorder sets up. He also shows, from a specimen, that polypus of the tube may likewise cause the same phenomenon. He figures a tubal sac, on the uterine side of which lies a small polypus which obstructed the lumen, so as to prevent the fertilised ovum from passing into the uterus. The ostium is very patulous. A less familiar

condition is held by DUNSMAN to be the cause of tubal pregnancy when evidence of inflammation or mechanical obstruction is absent. He finds that in seven of his cases the abnormal followed within a year a normal pregnancy. He carefully examined the tube in one of these cases, and found the most definite evidence of atrophy of its walls. This puerperal atrophy damages the peristaltic action of the tube, and as the lumen is dilated, the entry of spermatozoa is favored. The weakened tube then fails to propel a fertilised ovum into the uterus.—*Brit. Med. Jour.*

Rupture of Uterus in Labor from Hydatid Disease of Pelvis.

TISSIER records a case of high importance in regard to pregnancy in women who have suffered from hydatid disease of the liver. His patient had been under treatment for that malady eighteen years before the pregnancy for which he attended her. During labor the uterus burst and shed. At the necropsy, the diagnosis of the hepatic disease was confirmed; the omentum and abdominal cavity were full of hydatids. The uterus was surrounded by a mass of the same growths; it is not actually stated that any of them perforated the uterine wall. Other hydatids were encapsuled in the broad ligaments.—*Brit. Med. Jour.*

Tubercular Peritonitis.

In an article on this subject in the *Annals of Gynecology and Pediatrics*, HOLMES arrives at the following conclusions:—

1. Tubercular peritonitis is a relatively common disease.
2. It is never a primary disease, though it is usually impossible to find the initial focus.
3. Recovery follows laparotomy as a general rule, unless there is an initial focus remaining to keep up the disease.
4. This disease appears in three forms: the exudative form, the dry form and the ulcerating form, and they are recognizable in the order named.
5. Microscopical examination of the peritoneum is sufficient for a positive diagnosis. The demonstration of microscopical tubercles or the recognition of the bacilli are only confirmatory.
6. Puncture of the abdominal wall for diagnosis or for the removal of ascites and injection of air, fluid or iodoform, is dangerous and should not be practised.
7. Laparotomy, with iodoform gauze, tamponade drainage is the safest and most reliable treatment.
8. Laparotomy should be done as soon as there is a show of emaciation or when a relative diagnosis has been made.
9. A positive diagnosis can never be made before laparotomy.—*Ballard's Med. Jour.*

Present Status of Vaginal Operations for Diseases of the Pelvic Organs.

DR. EDWIN B. CRAIG, of New York, read this paper. He was of the opinion that, with the exception of cases of small ovarian tumors, and prolapsed and diseased ovaries needing removal, unilateral disease of the appendages is best dealt with from the abdominal incision, and he also preferred the abdominal route for cases of ectopic gestation except in cases in which a hematocoele had formed and had become encapsulated. The vaginal operation he had found very useful in cases of pregnancy in which the parturient canal was obstructed by tumors. The vaginal operation was useful chiefly in three classes of cases, viz. 1. Pus-cases, in which the removal of the uterus and appendages is indicated. 2. Cases in which the exudate indicates the necessity for drainage without removal of the organ. 3. Small fibromyomata.—*Phil. Med. Jour.*

Intestinal Obstruction associated with Twisted Ovarian Pedicle.

TWO cases are reported by SCHALITA (*Vratok*) in both of which the intestinal lesions were much less severe than the disturbance in the original seat of the disease. The first case, *et. 20*, was supposed to have an epigastric tumour. Suddenly accompanied by violent pains in right iliac fossa and no motions passed for several days. Abdominal section showed large ovarian cyst with twisted pedicle adherent to great omentum and pressing so hard on a point in the ascending colon as to render it gangrenous. The tube was loaded with clot. The cyst was removed and the patient recovered. The second case, *et. 51*, whose abdomen was swelling for two years, was also suddenly taken with pains and intestinal obstruction. Abdominal section showed a loop of intestine strangulated between the abdominal wall and the ovarian cyst whose pedicle was twisted, and there was hemorrhage into the cavity of the cyst: Removal resulted in recovery.

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.

The Physiology and Pathology of the Pleura.

R. GRAWITZ, claims that it has been frequently proven that tubercle pigment is deposited not only in the lung and its pleural covering, but in the costal pleura as well, and questions how it gets there.

In experiments on rabbits, GRAWITZ found that pigment is very rapidly deposited in the costal pleura, and he was able to demonstrate the same in large quantities as early as twenty-four hours after blowing dust through the air-passages into the lungs. By creating a pneumo-thorax on one side of the animal, he found that, on this side, the lung, its pleura, and the costal pleura did not show pigment.

He, as well as FRIMMER, concludes, that inspired dust passes rapidly through the lung into its pleural covering, and part of the pigment is taken up by the costal pleura in turn.

If these deductions be correct, they would tend to explain the occasional so-called idiopathic cases of pleurisy, by the possibility that certain kinds of dust, while causing no pulmonary disturbance, might give rise to inflammation of the pleura by irritation, thus not necessarily requiring a bacteriological origin. GRAWITZ'S experiments may also have a bearing on primary tubercular pleurisy by the same mode of infection, the lung having escaped.—*Post Graduate*.

Quantity of Ammonia contained in the Blood under Physiological and Pathological Conditions.

DR. H. WINTERBERG, basing his conclusions upon an examination of the blood of twelve healthy persons, states that the average quantity of ammonia in the circulation is 0.96 mgm. in each 100 c.c. of blood, this quantity varying slightly in each individual, as do the salts, etc. The quantity varies greatly in fever; it is usually increased, but may be unaltered or diminished. More important are his observations of the uræmic state, in which he noticed but a slight increase in the ammonia, once up to 2 mgm., once to 1.4 mgm. The blood of a dog after extirpation of both kidneys showed no change in the amount of ammonia. This experiment, he thinks, tends to prove the fallacy of FERRISSON'S theory that uræmia is due to an accumulation of carbonate of ammonium in the blood.—*N. Y. Med. Rec.*

Symptomatology of Hæmaturia in Children.

As it may be constant, slight, profuse or intermittent and arising from any part of the tract, or may be so minute as to escape ready detection, MORRIS (Trans. Lond. Med. Soc.) lays great stress on the importance of finding out the origin of the hæmaturia, since it may indicate a local or a general disease. It is often the earliest symptom of scurvy rickets, and in young infants often occurs as the result of irritation of the renal tissues by uric acid and other crystals, or it may be induced by drugs such as cantharides, carbolic acid, potass chloras, rhubarb, turpentine, &c. Urine, tinged more or less with blood, is often found in Bright's disease, hemorrhagic measles, small-pox, diphtheria, uricacidemia, and scarlet fever. Both ABERCROMBIE and HAIG have found Raynaud's disease associated with hemoglobinuria, which is also common in purpura and in hæmophilia, where the bleeding from the kidneys is often profuse and intermittent. Winekel's disease, which attacks new-born infants on or about the 4th day and carries them off in 48 hours, is not common in England but paroxysmal hæmaturia or hemoglobinuria, sans blood corpuscles, yet highly stained with blood, is fairly often found. HERRINGHAM and VOLLMER appear to think that hæmaturic children have a syphilitic

taint about them, but MORGAN has seen typical cases in which no such suspicion could have existed. Bloody urine may be the result of direct violence or the reflexes of some tumour or otherwise diseased conditions, but is more profuse when from the kidney than when from the bladder, but is seldom accompanied by pain unless clots form in the ureter, and the pain, which is referred to the loin, testis or thigh ceases when the clot is washed onwards to the bladder. Kidney hæmorrhage may generally be confirmed by the presence of casts and epithelium.—*Lancet*.

Toxic Effect of Extensive Burns.

Is proven by the invariable fatal results obtained by TOMMASOLI (*Monat. Prakt. Derm.* XXV. 2) on dogs fed with the serum or meat extracts of other dogs that had been burned; but these fatal effects were averted if, at the same time he injected artificial serum, which he therefore considers the logical treatment for extensive burns.

Optic Atrophy following Sexual Excess.

SPALDING tells of four cases where sexual excesses led to optic atrophy which, refusing to yield to treatment of any sort, gradually became worse. The sufferers were not totally blind, though they had lost useful vision.—*Cincin. Lancet Clinic.*

Adrenal Growth.

REFERRING to the importance for a systematic study of such cases with a view to gaining definite knowledge of kidney and tumours, KELYNACK restricts himself to growths of the normal adrenal which he classifies as (1) *benign* growths of which adenoma and modified adenomata are the most frequent forms, and among which are such forms as lipoma, fibroma, glioma, angioma and lymphangioma, which seldom or never alter the shape of the gland, even when greatly enlarged; (2) *malignant* growths of which the usual primary form is sarcoma which secondary deposits in the suprarenals may develop into carcinoma. Primary cancer of the adrenals is excessively rare, and it was deeply regretted that most authors who had written on these subjects had given such scanty information on important points as to render their communications almost worthless.—*Med. Chron.*

Varieties of the Cholera Vibrio.

KLEIN, in the previous report, described several modifications of the typical Koch vibrio, by cultivation in oysters and in sea-water, and now describes the continuation of this work. No less than eight varieties have been obtained differing in the number of flagella, the rate of liquefaction, the length of the filaments, virulence, etc., some of them approaching very closely the Lisbon, Seine and other varieties. Although all were derived from a vibrio which reacted typically, some of the varieties reacted positively to the BORDET-DUREAN test, whilst others did not. Attempts to reconvert these varieties to the parent form failed, with one exception.—*Treatment*.

Frequent Occurrence of the Loeffler Bacillus on Wounds after Galvano-Cautic Removal of Tenail.

IN 11 out of 27 cases the author found LOEFFLER bacillus with streptococci and staphylococci and leptothrix. In spite of the diphtheritic appearance of the wound all of the cases recovered without the use of antitoxin. He regards the bacillus as harmless under these circumstances.

2. The transmission of vasomotor impulses from the nose.

3. Diminution of the breathing capacity from nasal causes.

4. Functional insufficiency of nasal resonance. He lays especial stress on the second point.—LICHTWITZ in *Jour. Eye, Ear and Throat*.

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE

Unusual Case of Poisoning by Sewer Air

In driving a tunnel in connection with the sewage works now in progress in Melbourne, foul air came out of such a deadly character as to cause the death of five workmen. The tunnel was through soft silt and sand on the bank of the river, which has been dug with drainage for years. Some time ago, the contractor and foreman of the works were nearly suffocated by the gases coming from the soil, and Dr. CHARLES BAKER, who attended them, described the symptoms produced in a paper in the November number of the *Intercolonial Medical Journal*. He concluded that the gases present were marsh gas, sulphuretted hydrogen and carbonic acid. On the present occasion the contractor had forbidden the men to go down, but three of them went to get some tools left in the tunnel and the other men went to rescue them. Several rescue parties of firemen in smoke jackets went down back by the same in attempting to remove the dead bodies. Finally, the tunnel had to be flooded with water and the bodies were brought out by divers. At the inquest Dr. MILLER, who made the post-mortem examination, said that death was due to suffocation from breathing irrespirable gas which was, he thought, chiefly carbonic acid.—*Lancet*.

Sanitary Value of Singing.

BATH maintains that singing is as good as any other form of gymnastics if not better than many of them, since utilization of the vocal apparatus clears the upper air-passages and promotes pulmonary circulation, besides developing the chest and the activity of the digestive organs by purifying the blood and regulating metabolism. Singing has also the advantage that it can be practised anywhere or at any time and without using special apparatus.—*Archiv. fur Laryng.*

Purification of Water Supplies.

In his address on State Medicine, Dr. GEO. H. ROHR pointed out that those cities that had the largest mortality from typhoid had a highly suspicious quality of drinking water. He urged the necessity for limiting—because it was impossible to altogether prevent sewage pollution, and showed that filtration through sand-beds are much easier and more practicable than any other modes of purifying a water supply; but adds that certain precautions are necessary to see that the layers of sand, which should be clean, are sufficiently close and that the passage of the water to be operated through these sand filters is slow enough to ensure dynamic and chemical removal of impurities.—*Univ. Med. Jour.*

Asepsis in Daily Life.

A MEASURE looking toward greater cleanliness, which means, of course, less disease, is now being pushed forward with some degree of success. This is the measure to prevent the floors of men and the sidewalks from being used as spittoons. The degree of success that shall attend this movement is a gauge of the civilization and refinement of the present day.

Beyond this, however, there is still an advance step that can be taken that would be wonderfully conducive to asepsis in daily life, and hence cause a still greater lessening of disease, writes JULIA W. CAMPBELL, M.D., in the *Woman's Medical Journal*. It is a simple but a very radical measure.

A handkerchief should be made of some inexpensive material, and when once used, it should be cremated.

This should be the universal law for sick and well. Think of the chronic catarrhs, the sorethroats, the decayed teeth and untidy mouths, the bad colds of well people—so-called—and the handkerchief, the receptacle of the exudates of all this.

All these discharges should be burned and the handkerchief thrown in the fire to destroy them in the laundry. This simple step, this advice makes the opportunity of being carried out into the sewers and streets and returning again to the clothing boxes. As many a little makes a mickle, it is easy to see what pollution of water could in this way be prevented.

Handkerchiefs could be made of some material so inexpensive that their use and destruction would cost no more than their laundering. If the expense was something more, however, it would be nothing to the expense of disease. Cheap handkerchiefs to be burned would greatly facilitate the carrying out of the measure to prevent expectoration in cars and on sidewalks. The handkerchief could be the receptacle and its destruction would be such an advance toward aseptic living that there would be a great decrease in the number of influenza, catarrhs, and especially in contamination from tuberculosis.—*Galliard's Med. Jour.*

Recent Observations upon Cocaine Poisoning.

GARVIN calls attention to the variety of susceptibility and idiosyncrasy to cocaine which different individuals present. Some patients who are acutely poisoned exhibit maniac excitement, while others are stupid. It is well known that poisoning has followed the use of a dose far short of the maximum therapeutic allowance, even 0.77 of a grain having caused serious symptoms. There are also instances in which a solution of a certain strength has been used without unpleasant effects, while a repetition of the same dose on a subsequent occasion has caused toxic symptoms. The injection of camphor dissolved in ether and the employment of artificial respiration have recently been extolled as the best treatment for the acute poisoning.

In chronic poisoning by cocaine there is one symptom known as Magnan's sign, which is of considerable importance in establishing a diagnosis when the use of the drug is denied, and is also of importance in other cases as indicating to the physician the necessity for immediate discontinuance of the remedy. This sign is a hallucination of sensation, the patient complaining of feeling some foreign body beneath the skin. This is generally described as being small in size, and is usually ascribed to the presence of "sand," "worms," or "microbes".—*Med. News*.

Examination of Patient under Chloroform.

In a personal injury case, a physician was called by the plaintiff, and testified that chloroform was administered to the plaintiff, and that she was examined while under that influence, and as to what he found in reference to the condition of his patient at the time. The defendant contended that an examination of the plaintiff's injuries had been made by the doctor only a day or two before this without administering chloroform, and that this testimony about giving it had a tendency to make the plaintiff's case appear more serious than it really was, and that this was prejudicial to the defendant. But the supreme court of Michigan says, HOLMAN against Union Street Railway Company, that the chloroform was administered as a part of the treatment, and while the patient was under its influence, the muscles of the shoulder and hip were given action with the purpose of breaking up the adhesions; and it expresses the opinion that the testimony was not objectionable, and was introduced for the purpose of showing the true condition of the plaintiff. This decision is further worth to justify by the statement that there was nothing in the testimony to show that this treatment was unnecessary, or that it was had for the purpose of the trial of the case. That the doctor was asked, while upon the stand, whether or not in his judgment the plaintiff still continued to suffer pain, and whether she would be able to do her household duties, it does not constitute error.—*Jour. Amer. Med. Assoc.*

TUBERCULIN AND TUBERCULOSIS.

Treatment of Tuberculosis.

V. ZIMMERMAN draws attention to the still very imperfect state of our knowledge of tuberculosis. The diseases (1) the specific, (2) the alveolar, (3) the alveolar disease. His results with the new tuberculin have been satisfactory, although KROHN's directions were strictly adhered to. Occasionally the author has observed an increase of weight, diminution of expectoration and fever, while tuberculin was being used, but the same has been known to occur under other conditions. In local tuberculosis of the skin, bones, and joints, perhaps the results of the tuberculin treatment may be different. For instance, the author has recently seen a case of lupus under POISSONET's care in which tuberculin had brought about a cure. V. ZIMMERMAN says that he has no expectorations either from the tuberculin treatment or that by MARAGLIANO's serum. The condition of the lungs is far too complicated to admit of a direct action of the tuberculin upon the pathogenic microbes. The lung cannot be protected from the streptococcus and staphylococcus infections. The value of the open air treatment of phthisis is universally admitted. The advantages of high altitudes lie (1) in the air being purer and freer from gases and bacteria, (2) in the greater amount of ozone present, (3) in the diminished pressure; (4) in the rays of the sun being warmer, the air drier, and fog rarer; and (5) in the increase of the red cells induced. The increase in the hemoglobin does not depend on the high altitude. The hardening of the body against atmospheric agencies by the outdoor life and hydrotherapy as well as the increased appetite can be brought about elsewhere. The disadvantages of high altitudes consist in the variation in wind, rain, and snow which may make acclimatization difficult. There is also the difficulty in the journey. The treatment in the majority of cases has to be carried out at home. Some well-known sanatoria show that phthisis can be as well treated in ordinary as in high altitudes. The author lays much stress on the formation of such sanatoria for all classes of the community, in them really lies the future of a more efficient treatment of phthisis. —*Brit. Med. Jour.*

Euphthalmine, a New Mydriatic.

DR. B. TRENTLER reports his investigation of euphthalmine. It is the hydrochloric-acid salt of a mandelic derivative of methylmethyl-diastonealkamine.

1. It causes slight discomfort of short duration.
2. It dilates the pupils, solutions of five to ten per cent. being used.
3. Its action upon the old is not so marked.
4. It is not as rapidly absorbed as cocaine, but once established, the effect is more intense or lasts a longer period. The corneal epithelium remains intact.
5. Accommodation is less influenced by euphthalmine than homatropine.
6. The return of accommodation to the normal state is much quicker than after homatropine.
7. Disagreeable sequelae have not as yet been observed.

Post Graduate.

Chloroform as an Anthelmintic.

CARRATO draws attention to the value of the internal administration of chloroform in cases of tape-worm. He reports seven cases in which it was eminently satisfactory after the common anthelmintics had failed. The patient is put on a moderate diet for two days, but not made to fast, and then, in the course of eight hours, he takes from forty-five grains to a drachm of pure chloroform in syrup, a quarter of it at each dose and a dose every two hours. After that

a dose of castor oil is taken. In the majority of cases there were no symptoms of poisoning or any unpleasant effects. This treatment is said to have been described by an American writer in 1888. —*N. Y. Med. Jour.*

Therapeutics of Whooping Cough.

ACCORDING to Rudragli's experience a treatment that disinfects, soothes the nervous system and keeps up the strength is much better than any of the so-called specifics. For the first he advises spraying for ten minutes a day with a 2 per cent. solution of carbolic. For the second he prefers trional, which ensures a calm, lasting and strengthening sleep, 0.1 to 0.5 gram according to age. He adds a teaspoon of a 1 per cent. solution of chloral in every obstinate case. To keep up the strength he gives one-fourth to one-half teaspoon somatose in milk three or four times a day. —*Atta. Therap. Week.*

Treatment of Chronic Appendicitis by Mercury.

FOUR persons who had several times refused operation for chronic appendicitis, contracted secondary syphilis for which they consulted HORWITZ (*Annals of Surgery*), who put them on small 'tonic' doses of protoloids of mercury, and was surprised to note that not only the syphilitic symptoms disappeared, but also the appendicitis, dyspepsia and constipation. The appendix has not given any trouble since the cessation of the mercurial course some 18 to 48 years, but these cases are too few for definite conclusions. HORWITZ thinks it well worth while for others to test this treatment in all cases of chronic appendicitis, where operation is refused.

Hair Tonic.

R	Bailey's acid	18 grains
	Resorcin	30 grains
	Tincture cantharides	4 drachms.
	Tincture capsicum	1 drachm.
	Saponin	1 drachm.
	Lanolin	1 ounce.
	Rose-water, to make	10 ounces.

Melt the lanolin, dissolve the saponin in the same quantity of water, incorporate the two. Dissolve the acid and resorcin in the tinctures and rose-water, respectively, make up the required bulk.

Dose: For a child of 6 months, half a teaspoonful, from 6 months to 2 years, one teaspoonful.

Dr. Blackwell's cure, however, is not the abolition of standing armies, this would not be effectual, for she is forced to admit "that the same dangerous diseases prevail in all our larger towns." Well, we say, like charity, let Dr. Blackwell and her followers begin at home, they will find a rich field ripe for their labors; let them tap the evil at its root, purify the civil population and, ipso facto, the army will be purified.

Such advice is a however, unpalatable to them who love the sensational notoriety of big meetings, and platform declamations.

What can be more outrageous and reprehensible than such a statement as the following which we find in Dr. Blackwell's address:—

"It is stated that, according to the last census, there were the enormous number of 33,047,354 girls under 15 years of age in our Indian Empire. What is the duty of a Christian Government to this helpless mass of human beings? The formation of poor young Indian women into a class purchasable by white soldiers—a class despised by their own people, with no refuge before them: but even used up, turned out to die, is a dire and dastardly disgrace to any Government calling itself civilised."

Is this the language of sanity, or is it the irresponsible utterance of an unprincipled agitator?

Does Dr. Blackwell desire to lead those more ignorant than herself into the belief that the Government of India thus disposes of all the young girls in the Empire? Or does she wish to imply that prostitution was unknown in India before the advent of the British?

She says: "The sexual organs are not a permissible subject of study." What grounds does she make such a statement, especially as the grounds of history or common sense are a very long way from her side. This is the oldest trade in the world.

THE CHEMIST AND DRUGGIST TRADE IN INDIA.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—The chemist's shop with its colored earbays and gold labelled blue bottles does not seem to offer the same attractions now as it used to some time ago to the uninitiated, and it would not be wrong to state that most of those in the business, if given the chance of beginning life again, would not select the drug trade to pass their days at, nevertheless the Trade is not "Done" as most imagine, but on the contrary, is still able to give one more than a subsistence, if persevered in. This calls to mind the signboard of a chemist which stated that he could cure every ill; prevent every disaster, and soothe every disappointment. The remedy, when applied for, as every one knows, was—

"Patience" is the pill
That cures every ill;
"Take care" is the plaster
That prevents disaster;
"Good temper" is the salve
Soothing every disappointment.

maxims which, if followed, would secure the success of almost any undertaking or calling in life.

The same or rather cause for the apparent falling-off of candidates for pharmaceutical work, natives excepted, is partly due to the old complaint of long hours and low wages, and to which must now be added the want of a boundary line between the medical practitioner and the pharmacist, and that the not least (what should be illegal) the dispensing of drugs by the

with an army of two penny and penny, shillings and shillings shops.

The Government certificate of efficiency granted to successful candidates states that in the opinion of the Examiners the candidate "has a sufficient knowledge of English materia medica and pharmacy," but this to all experience is far from being the case. The English referred to is confined to prescription-reading and the poisonous table, and that even is very imperfect and the so-called knowledge of *Materia Medica* and *Pharmacy* is nothing more or less than "cream." Certainly it is not knowledge, for if you ask ten locally qualified compounders the difference between percolation and distillation, or what a percolator, an infuser or a distiller is, and you will be amused at the replies to the three former queries, and very probably you will be told that the latter three drugs must be unofficial remedies and not among B. P. preparations. This state of affairs points to the necessity of a more practical and higher standard of examination which should include elementary chemistry and botany. Doubtless the right sort of men in large numbers would come forward to weed out the present class of compounders, who are clumsy assistants requiring more supervision than one can find time to give them. It must not be inferred that the exclusion of honest competition is aimed at, rather the reverse, as competition at all times is healthy and desirable, but it must be on equal terms, otherwise it becomes as great a scandal and a disgrace as the monopoly by official medical men of hospital and private practice against the equally qualified private medical practitioner. What, may I ask, is there to prevent the dismissed compounder in the late unfortunate case in the N. W. Provinces from opening a drug store in Bow Bazar or Bhowanipore, dubbing himself an M. D. of the U. S. A. or Afghanistan, it does not matter which, under the name and style of Cureall and Company, Surgeons, Chemists and Druggists. Is this competition? It is more like legalised manslaughter. Then why not protect the lives of the people and the professions who alike contribute towards the payment of the handsome salary of that high officer of the State whose one duty is the inspection of hospitals and dispensaries, their constitution and working material. Yet there are hundreds of the "killaway dams" pictured above, in and around every city and town, that have never yet been entered, though seen by the medical war horse at Writers' Buildings. But to return to our subject, apart from the disadvantages and drawbacks enumerated, the shop life in the drug trade is far and away superior when compared with most other classes of business. It has its humorous side the same as other shops; in fact more amusement can be derived in the chemist trade in a week than in any other business in a month, the curious requests, the whisper which is intended to be strictly private, the wonderful and extraordinary descriptions of complaints is amusement enough, to be asked for something for a boil "as per margin or something for "an ulcer" in the throat; or for constant vomiting by the mouth, for a fever mixture for pains in the bellies and the bodies by fever, will extract something more than a smile from the prescriber, besides there is not that stream of customers seeking for half price bargains as is the case in other shops, and therefore not that continual work, though the hours

be long. All things considered, the calling has many advantages over other services, though the disadvantage of the chemist to-day is that he is more troubled in the execution of his duties than his predecessor of ten years ago, when a good prescription could be dispensed with B. P. preparations, but now it is the fashion probably due to the microbes which necessitate the turning of new remedies and preparations on him by the physician, and which does not give one the happy time which formerly was his lot.

Yours &c., O. C. D.

A PRIVATE TEMPERANCE HOSPITAL IN BOMBAY.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—The above institution was opened in Bombay, at Mangan, on the 8th March 1898 (under the auspices of the W. C. T. U.), for all classes, sexes, doctors, to be worked, as far as possible, on the same lines as that of Doctor RICHARDSON'S "London Temperance Hospital," which has now been worked for 21 years with 95 per cent. recoveries.

Private.—Every Home arrangement to be made.

Temperance.—No alcohol, as brandy, whisky, wines, to be admitted into the hospital as beverages.

All Classes.—For Hindus, Mahomedans, Parsees, Jews, and Europeans.

Sexes.—Men, women, and children will be received.

Doctors.—Any doctor's patients will be received, provided the doctor consents to treat without the use of alcohol, unless absolutely needed, when a full record of the case must be made in a book kept for the purpose.

It is optional for the patients to be under the inclusive professional charge of the Resident Medical Officer of the hospital, or to call in, at their own expense, any legally qualified medical or surgical practitioner whom they may think proper, subject to the rules of the establishment.

The hospital is big enough to contain 12 single paying wards and 4 free beds, with a dispensary and quarters sufficient to accommodate the hospital staff.

The terms of admission will be as follows:—

1. The charge for board, nursing, and medical attendance in the hospital, by the staff, will be at the rate of Rs. 5, Rs. 2, and Re 1 per diem for 1st, 2nd, and 3rd class patients, respectively, payable in advance.

2. The Resident Medical Officer may determine the patient's term in the hospital by a week's notice or less if necessary, upon a certificate by the doctor-in-charge of the case that the patient is in a condition to be removed.

3. The patients must in all respects conform to the regulations prescribed from time to time for the due government and management of the hospital, and all matters incidental to their position as patients therein and removal therefrom.

4. Whenever practicable, accommodation will be provided in the hospital for such relatives or friends as a patient may wish to have near, upon the distinct understanding that they will strictly conform to the regulations. The charges for board and lodge to such visitors will be Rs. 2-8, Rs. 1, and Rs. 0-8 for 1st, 2nd and 3rd class respectively.

HOSPITAL TREASURY.

This being a philanthropic movement, and the charges so moderate as to scarcely cover the entire cost, the public are earnestly solicited for donations and subscriptions.

Donors of the following sums will have the honor of being reckoned as follows:—

Rs. 1,000 ... Life Councillohrs.
Rs. 500 ... Life Members.

Annual donations of Rs. 300 will defray the cost of a "free" bed, which will be named after the donor as long as the donation continues. There will be four such beds.

LADIES' COMMITTEE.

President.—Mrs. THORNTON, M.D. *Treasurer*.—Mrs. Dr. CHRISTIE. *Secretary*.—Mrs. Dr. VAN INGEN, M.D., Mrs. STEPHENS. *Bankers*.—National Bank of India.

The hospital has won the sympathy and support of an influential section of the European and the Indian communities of Bombay. We now ask for the support of readers of the *Indian Medical Record*.

Yours &c., ALICE VAN INGEN, M.D.,
Physician to the P. T. H.

**APKE-WASTAISM IN CALCUTTA.
SALAAMING OFFICIALS.**

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—There is an expression in China which is on all fours with the vulgar one in English called "Nok-spit," it is "tow-tow." In plain English it is sycophancy of a very humiliating order, a desire to obtain the smiles and favors of those in high office by falsely praising them, by getting up shows for departing officials who do not deserve an expression of public thanks or public appreciation. Yet there is a small section of Bengalis in Calcutta who can manufacture a tin-pot show of this kind for any and every official, who, having feathered his nest, puts on high airs of funkyleam and so-forth, slides off the stage of Indian affairs with no more title to credit or thanks, than Shylock. Money grubbing, whipping up the almighty rupee, has of course been a well played game, but science, research, the up-building of the profession, the enrichment of the clinical annals of medicine, reformation in educational and other medical matters, are all outside the pale of official concern with some such beings. The wonder of these complacent and meaningless shams is, that officials who are credited with some degree of common sense and self-respect, stoop to permit themselves to be duped in this fashion and to be made a public laughing stock. Truly it is officials of the bombastic, stand-off-the-grass type, who stab their non-official brethren in the dark, who calumniate them, who try in a hundred-and-one ways to harm them, these are the blatant apes who accept this buffoonery as "genuine" praise. A death to all such hypocrisy. May even Bengalis learn that such conduct is mean and contemptible, and that people without spectacles, men half blind with cataracts, can see through shams, and what is more, they will find these shams exposed and ridiculed in all their contemptible hollowness.

Yours, &c., ENGLISH NON-OFFICIAL.

MORE HIGHLY PLACED ANGLO-INDIANS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I thank you for publishing my letter giving the names of a few highly placed Anglo-Indians, and as promised, I now send you a supplementary list, to which I hope to be able to add from time to time.

1. George Elander, Executive Engineer, Karachi Canal. (Died 14th September 1872).
2. Theophilus Miles, Deputy Collector, Shikarpur, Sind (Retired).
3. Francis Gibbons, City Magistrate, Karachi. (Retired).
4. Charles Barry Chetham, late Manager, Agra Bank, now Secretary, Chamber of Commerce, Karachi.

5. Anthony R. Cumming, City Magistrate, Karachi.
 6. Hope Bealish, Surgeon-Major, Indian Medical Service. (Retired).
 7. Victor Hope Bealish, (Cooper's Hill) Assistant Traffic Superintendent, North-Western Railway (Covenanted).
 8. William Dewman, Deputy Collector, Hyderabad, Sind.
 9. Henry Celestine Robert John, (Cooper's Hill) Executive Engineer, Sind Irrigation Department.
 10. John Wright Sandford Drouap, Assistant Commissioner, N. D., Bombay.
 11. William Edith Young, Assistant Collector, of Customs, Bombay.
 12. George B. Strettell, Conservator of Forests in Sind.
 13. George Charles Gilder, Assistant Secretary to Government, Bombay (retired).
- The following are some "stars" Anglo-Indian ladies:—
1. Blanche Fearn, M.D.
 2. Matilda Hunt, M.A., S.C., L.M.S., Senior Fellow D. J. Sind College, and Editor, *The Phoenix*, now Lady Superintendent, Alexandra Native Girls' English Institution, Bombay.
 3. Margaret Evans, B.A.
 4. Olive DeCunha, B.A.
 5. Helena Payne, B.A.

Yours &c., W. H. T

KARACHI, 6th April 1898.

(These lists are very creditable to Bombay, we want Madras and Bengal to follow suit.—Ed., I. M. R.)

BOGUS INSURANCE OFFICES.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—May I request you to kindly inform me whether you know anything about the "Sun Life Assurance Company of Canada."

I insured my life in it some five years ago. I do not know whether that Company transacts any business in India. The Chief Agents for the Company in India are said to be "G. M. LALKA SON & Co., Bombay."

Is it a Company worth having one's life insured in?

Is the Company as good as the Oriental Insurance Company of Bombay?

Is it suited for residents in India?

I saw something about American Life Insurance Companies in your journal, hence I take the liberty of asking you to let me know about the "Sun."

What will be the best means to get a portion of the premiums paid?

Yours &c., M. MUNUSAWMY IYER, C.M.S.

Medical Officer, Tanjore Jail.

(We know nothing of the "Sun" Insurance Company. We accept the advertisement of none but genuine Insurance companies in the Record, and our correspondent will do well to trust these Companies only. It is an unfortunate fact that American Insurance offices cannot give useful information to insurers without referring to America.—Ed., I. M. R.)

AMERICAN MEDICAL DIPLOMAS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I note, by regular perusal of your valuable journal, that you are an active advocate of an impartial yet high standard of education for all medical practitioners in India. The time cannot too quickly come when this much-needed improvement shall be realized.

It is not only distressing to the hard-working and well-informed physician, but it is a crime against suffering humanity, for the great number of so-called "Doctors," without education, and without conscience, to thus live at the expense, and prosper by the downfall, of those who have no means of knowing, until too late, that they are being imposed upon.

I wish to add to the volume of Dr. Forster's article with reference to so many bogus American medical colleges, in which article the impression is given, that diplomas may be secured in America for money only.

We recognize that there are cheap and worthless in America.

We have met some of the same class in England and on the Continent, but to illustrate any national standard by individual singularity, is doing ourselves, as well as the country, an injustice.

We anxiously look for the time when India shall have secured equally stringent laws and high standards, governing the practice of medicine, as may to-day be found in the States, or in Canada.

"America" has many schools, some of which belong to Great Britain, and some to the United States. From which country these bought diplomas are coming, is not stated by Dr. For.

We are personally acquainted with the Canadian medical standards, and have done some work in the States, but although we occasionally hear of such "American" diplomas, we have not as yet been able to get our hands or eyes upon even one such document, although we have, (for special reasons) been very desirous of so doing for several years.

Any physician knowing of such diploma being now in use in this country will confer on us a great favor by simply stating its location.

Yours in the interests of better protection for the hard working and properly qualified medical practitioner,

O. G. PLACE, M.D.

(It gives us much pleasure to publish Dr. Place's letter. We have always held that America is second to no country in the world for the high standard of many of her medical schools and the excellence of her physicians. But that bogus diplomas exist in that far advanced Western clime is proved by the almost weekly protests of the best journals of that country. We must indicate an error into which Dr. Place has fallen, namely, that "some" American medical schools belong to Great Britain. This is incorrect. No medical school in either America (the States) or Canada belongs to Great Britain in any sense. Canada belongs to Great Britain, but her medical schools are her own, governed by her laws, and uncontrolled by the only body that controls Medical Education in Great Britain and her Colonies, namely, the General Medical Council. It is quite true however that the Council recognizes the diplomas of Canadian medical schools, just as she does those of England's other Colonies. Dr. Place has every right to be proud and jealous of the good name of American and Canadian medical education. Our only desire is to expose and crush down frauds.—ED., *L. M. R.*)

Book Reviews & Medical Trade Notice.

TEXT-BOOK OF PHYSIOLOGY.

EDITED BY E. A. SCHAFER, LL.D., F.R.S.,

Godrell Professor of Physiology, University College, London

(Publisher: Young J. Pentland, Edinburgh and London. Vol. I, 1898)

This excellent hand-book of Physiology is the combined work of the best physiologists of Great Britain, such names as Gamgee, Gaskell, Edkins, Hill, McKendrick, Blandford, Schaffer and others are in themselves a guarantee of the high standard of the book. It is a large volume of over 1,000 pages, and is essentially a work on "higher" physiology, intended chiefly for students and practitioners who are working for high academic medical and surgical degrees. As such it is undoubtedly a most commendable volume.

CARDIAC FAILURE.

By ALEXANDER MORISON, M.D. Edin., F.R.C.P., Edin.

(Publishers: The Robman Publishing Company, Ltd., 11, Adam Street, Strand, London W.C.)

To thoroughly understand the great pathological truths of cardiac failure it to be armed with knowledge of the most essential service to every physician. This little monograph, while it deals with all the pathological changes of heart failure in a general way, is very explicit in its

reference to the therapeutics of the subject and is especially on the modern treatment of cardiac ailments by baths and gymnastics. The work is highly interesting and instructive.

A TEXT-BOOK OF MATERIA MEDICA, THERAPEUTICS AND PHARMACOLOGY.

By GEORGE F. BOTLER, Ph.D., M.D.

Professor of Materia Medica and Clinical Medicine in the College of Physicians and Surgeons, Chicago.

(Publisher: W. B. Saunders, Philadelphia.

Price 4 dollars.)

This large volume of 858 pages provides the student of medicine with a clear, concise and practical text-book, adapted for permanent reference no less than for the requirements of the class room. The design and arrangement of the various sections is most philosophical and rational, and will be found well calculated to remove all perplexity in the study of these subjects. While the educational value of this book is very good, the pharmaceutical section is particularly well arranged and is very interestingly instructive.

"KASAGRA" (THE ORIGINAL AND ONLY GENUINE CASCARA AROMATIC.)

FREDERICK STEARNS & Co., DETROIT, MICHIGAN, U. S. A.

1. The term "Kasagra" was coined and adopted to the medical profession and ourselves against the substitution of cheaper and inferior preparations bearing the name of "Cascara Aromatic," a title original with us, several of which have been put upon the market with the hope of gaining a sale on the reputation and advertising of ours, the original product.

2. "Kasagra" contains all the active principles of the best selected bark of Rhamnus Purshiana, and owes its laxative properties to this drug alone.

3. It does not gripe, as does the ordinary U. S. P. fluid extract. In preparing "Kasagra," bark two years old or older is used, which lessens its gripping tendencies and improves its taste.

4. It is highly palatable, the bitter principle being successfully masked without detriment to the therapeutic properties of the drug. It is the only strictly non bitter preparation of Cascara Sagrada of full fluid extract strength.

5. It is a true pharmaceutical preparation, and not advertised to the laity but only to the medical and pharmaceutical professions.

6. It is sold as reasonably as is consistent with the care and excellence of the ingredients used in its manufacture.

7. It is a true laxative and intestinal tonic remedy par excellence for chronic constipation. It is not a purgative and should not be used as such.

8. The aromatic used in the preparation of "Kasagra" produces a carminative and stimulating effect upon the elementary canal and are thus synergistic.

Government Medical Gazette.

GOVERNMENT OF INDIA.

Surgn.-Majr. Jarlath French-Mullen, M.D., Eugene Cratin, M.D., F.R.C.S., Andrew Deane, M.D., F.R.C.S., George Frederick Nicholson, M.D., F.R.C.S., Samuel Ferguson Biggar, M.D., Sir George Scott Robertson, M.C.S.I. to be Surgn. Lieut.-Col., 30th March 1898.

Surgn.-Majr. William Grant Thorold, Patrick Mohr, M.D., Lionel John Piesani, F.R.C.S., Rajendra Kumar Bera, M.D., Narendra Prannana Sinha, William Rice Edwards, M.D., Charles Macgregor, M.D., John Fenton Evans, M.D., George James Hamilton Bell, M.D., Joseph Thomas Daly, M.D., Henry Fooks, Ernest Hudson, M.D., Arthur Wilkes Dawson, M.D., William Henry Hauser Robinson to be Surgn.-Majr., 1st April 1898.

Hand sent, Chien-mei-shin, to Kharlanwa, Diapy, Jhan
 etc., from 11th Feb. 1898.

Qadh Amish. were temple, placed at the disposal of the Ohio
Gover. for Plague duty.

Hosp. Asst. Ashfaq Hussain, to the Nijeragun Branch Disp., Jubbulpore Dist.

Hosp. Asst. Ram Datta to the Sehore Branch Disp.,

Hosp. Asst. Abdur Karim, Sehore Branch Disp., to Khandwa on plague duty.

N. W. P. AND OUDH GOVERNMENT.

Surgn.-Maj. D. F. Barry, Civil Surgn., Gorakhpur, to hold visiting med. charge of the Basti dist.

Surgn.-Maj. W. G. P. Alpin, Civil Surgn., Fyzabad, to hold visiting med. charge of Bara Banki.

Asst. Surgn. Subhan Ali, Sadr Disp., Sitapur, to hold civil med. charge of that dist.

Asst. Surgn. Manmatha Nath Basu, Sadr Disp., Mirzapur, to hold med. charge of that dist.

Asst. Surgn. E. H. Thomas, Lecturer, Materia Medica, Medical School, Thomason Hosp., Agra, privilege leave for one month from 5th May 1898.

Asst. Surgn. Wasir Singh Sarin, Lecturer on Anatomy, Agra Med. School, to act as Lecturer, Materia Medica, &c. Asst. Surgn. Chanan Singh to do plague insp. duty at Saharanpur.

Surgn. Lieut.-Col. J. McConaghey, Civil Surgn., Lucknow, to hold visiting med. charge of the Sitapur and Kheri dists.

BURMA GOVERNMENT.

Hosp. Asst. Nuruddin assumed charge Civil Hosp., Letpadan, Tharrawaddy dist., 19th March 1898.

Hosp. Asst. Tifigul Hussain assumed charge of duties with Mr. Morris's Escort at Paingmaw, Bhamo dist., 24th Feb'y. 1898.

Hosp. Asst. Anant Singh assumed charge Civil Hosp., Paungda, Pegu dist., 22nd March 1898.

Hosp. Asst. Maung Kyaw Lun assumed charge Lunatic Asylum, Bangoon, 2nd Feb'y. 1898.

Hosp. Asst. M. Swaminatha Pillai assumed charge Police Hosp., Bhamo, 2nd March 1898.

Hosp. Asst. M. Swaminatha Pillai assumed charge Outpost Hosp., Myothit, Bhamo dist., 10th March 1898.

Hosp. Asst. Battam Chandra assumed charge Police Hosp., Bhamo, 11th March 1898.

ASSAM GOVERNMENT.

Sick leave for three days is granted to Hosp. Asst. Himat Deen.

Hosp. Asst. Sayyad Gyaeddin, a supy in the Goalpara dist., to the med. charge Bijni Disp. in that dist., from 29th March 1898.

Hosp. Asst. Hara Nath Mukerji, Bijni Disp., Goalpara dist., to the med. charge of the Bilaspur Disp., from 1st April 1898.

Hosp. Asst. Rajani Kanta Karmakar, Jhansi Disp., Sibsagar dist., was employed as a supy. under Civil Surgn. of that dist., from 16th Oct. to 4th Nov. 1897.

Leave for three months and twelve days is granted to Hosp. Asst. Rajani Kanta Karmakar, a supy., Sibsagar dist., from 5th Nov. 1897.

Hosp. Asst. Baikuntha Chandra Purkayastha, a supy. Kamrup dist., to Sylhet dist. to Coolie Depot Kulaura, from 16th Feb'y. 1898.

Hosp. Asst. Baikuntha Chandra Chakravarti, Nongpoh Disp., Khaul and Jaintia Hills dist., to Sylhet dist. to Coolie Depot at Shaktaganj in that dist., from 22nd Feb'y. 1898.

Hosp. Asst. Hara Lal Shome has passed the English Qual. Exam. 7th March 1898.

Hosp. Asst. Mohamed Tahir, Jowai sub-div. Khaul and Jaintia Hills dist., is transferred to the Nowgong dist. and apptd. a supy. for duty under Civil Med. Officer of that dist. from 15th March 1898.

DOMESTIC OCCURRENCES.

The charge for inserting a Domestic Occurrence is Rs. 1 for subscribers and Rs. 2 for non-subscribers, which should be forwarded in stamps with the announcement.

BIRTHS.

NEILL.—On 7th April 1898, at Ranaghat, the wife of Charles Neill, M.A., M.B., of a daughter.

JONES.—On the 29th March, at Poona, the wife of Surgn.-Major J. M. Jones, A.M.S., of a son.

STUART.—On the 28th March, at Sitapore, the wife of Surgn.-Major S. O. Stuart, A.M.S., of a son.

DEATHS.

GOVAN.—On the 1st April, at Almora, Brig.-Surgn. George Moncrieff Govan, M.D., Bengal, retired; aged 69 years.

STEPHEN.—On the 22nd March, at Dehra Ghazi Khan, Lieut. Arthur Sheldeman Stephen, L.R.C., Asst. Commr. Rajaspora, the only son of Surgn.-Col. Stephen, Principal Medical Officer, Amam, in his 27th year.

NOTICES TO CORRESPONDENTS.

P. V. N. (Jenapur).—Every member of the Indian Medical Association is entitled to put the letters M. I. M. A. after his name.

T. R. (Rawalpindi).—Your letters will appear in due course.

K. D. R. (Pithapuram).—Butler's *Materia Medica* and Ringer's latest edition of *Therapeutics*, both deal fairly fully with most modern drugs and recent pharmaceutical preparations.

G. R. M. (Bara Banki) wishes to be informed of the best method of treating local anaesthesia and local paralysis. We have tried subcutaneous injections of strychnine, (8 minims of the B. P. solution in 20 drops of distilled or pure water) used every second morning with much success. The fluid should be injected into the affected area.

T. D. (Kampti).—You will find all the information you require in the new edition of the *Medical Register and Directory of the Indian Empire*.

R. K. F. (Banarasi City) writes:—"Will any of your numerous readers kindly let me know any effective medicine for the following: Owing to continuous ill health, the growth of the breasts of a young lady has suffered very much. She now wishes that they should attain their proper size. She is between 16 and 17 years and is yet very weak. Any communication will be very welcome."

J. T. (Hosur).—Many thanks. We hardly know how to deal with the matter. A definite statement of the grievance might be published in the *Record* and the offender might take the hint and mend his ways.

Justice.—Next number.

Forlorn Hope.—Your views are sound and they will be published in our next issue. The "parings" you complain of have been done because hints were given from Head Quarters that certain concessions would be granted, and that for the present our demands should be limited to these lines.

N. E. J. (Khairpur).—Only one certificate of membership is granted to members of the Indian Medical Association. The fees are paid yearly to meet the expenses of the Association.

Anti Malthus writes:—"Your correspondent 'M. B.' in last issue, will get all required information about the check necessary from certain chemists in Madras, Bombay and Calcutta."

TREATMENT OF VERTIGO KNOWN AS MENIÈRE'S DISEASE.

DE LA TOURETTE reports the case of a man 58 years old. The patient, who had previously been quite well, was taken suddenly one morning in June 1898, with a violent vertigo, having all the features of Meniere's disease. Following this the patient complained of a persistent noise in the right ear, and of a continuous vertigo, for which he was given quinine in large doses with excellent results. *Après* of this case, the author takes up the history, causation, lesions, and diagnosis of Meniere's disease. He points out the rôle played by hyper-excitability of the labyrinth in the production of vertigo, and dilates on the efficacy of quinine in the treatment of the auricular forms of vertigo. The medication should be given in ten-grain doses once or twice a day for a period of at least a fortnight.—*The Post-Graduate*.

CLIMATE AND MALARIA.

Jalapahtar, Darjeeling.

L.

The ways in which these various and complex conditions and phenomena may affect H2O would form a

These may be termed local climates, and what I contend is, that it is only with such local climates we have to deal in the investigation of disease. When dealing with sickness in a specified locality, it is certainly useless to ascertain the climatic conditions of a place miles away, the only portion of the atmosphere that can affect a man is the portion in his immediate vicinity, his climate.

depends upon the state or condition of this portion of the atmosphere.

From these considerations we arrive at a corollary of the very greatest importance. MAN HAS THE POWER TO MODIFY THE CLIMATE OF A PLACE.

He can alter the nature of the soil, and he can govern the vegetation, by draining a marsh, he can lessen the amount of moisture in the air, and he can alter the temperature of a place by cutting down a wood or by planting one. Into these questions I will enter more fully by and by.

Plain and obvious as it is that man can modify local climates, and although he has actually done so in many occasions with excellent effect, the fact has not only been overlooked, but has even been denied by some of the best authorities.

JACQUOT¹ for instance a French writer of deservedly high repute, the author of the only attempt at a detailed criticism of the climatic theory of malaria that I have seen, based this criticism entirely on the idea that climate is immutable, and that man has no power to control it.

"The object of these memoirs," he says, "is to combat the opinion of some dissentients, fewer in France than Italy, but equally obstinate in both who deny the paludal miasm, and attribute the generation of these fevers to meteorological influences."

These memoirs were directed against MINZI, FOLCHI, BROGHI and more especially ARMAND.

He goes on to say:—"A government before devoting large sums of money to improve the hygienic condition of a country by draining its marshes must first decide, that it is in these marshes that the cause of the disease really is. If, on the contrary, the cause of the disease exists in the climate and in meteorological conditions which man is powerless to modify, humanity and hygiene should repress efforts to colonise countries condemned to eternal unhealthiness."

He gives the following example:—"The temple of Serapis, on the coast of Ponzioles, was inundated by the elevation of the bed of the sea, fever appeared. The Chevalier NICOLINI drained it and the fever disappeared; again the water returned and again the disease broke out, must we say that the climate was changed, the climate with its meteorological conditions, its heat, its moisture? Surely not!"

Such is JACQUOT's exposition of climate, a sufficiently erroneous one, I think, where the influence of climate on health is concerned. He is certainly right if he contends that the climates of the whole of Italy did not vary with the changes to which the temple of Serapis was subjected; he is certainly wrong if he asserts that the local conditions of the atmosphere underwent no alteration.

But the climates of the rest of Italy had no bearing upon the case whatever, the conditions were purely local, the fever was local, and so were the changes in the heat and moisture of the atmosphere.

JACQUOT's whole memoir is so vitiated by the sense in which he uses the term climate, as to be practically useless.

KELCH and KINNE² have fallen into several errors on the subject of climate, which it is the fashion to consi-

der such a simple matter, that I doubt if any lecturer on climatic disease ever wastes a word upon it.

"In all parts of the world," they say, "we find districts close together, with the same climate, some of which are notoriously malarious, while in others malaria is either absent, or only prevails in a non-endemic form," and as examples they give,—it is almost incredible, yet it is true, these up-to-date authors mention as districts lying close together and having the same climate, Bengal and Madras!

This is an example of the way in which the poor word climate is abused, which, I think, puts all others into the shade.

In continuation of this passage they say:—"From this contrast we are justified in concluding that the cause of the fever is not to be found in the climate;" the value of such a conclusion is obvious, but they continue and immediately fall into another mistake, and such a fundamental one that I am puzzled to know if it does not equal, or even exceed that just quoted.

"If further evidence were required," they say, "it is at hand in the well-known immunity enjoyed by ships lying off the most unhealthy coasts."

According to these authorities then, the crews in the ships and the people on shore have the same climate; and thus they deny one of the primary divisions of climate, the "Oceanic."

Now the oceanic climate is one apart from and distinct from all other climates, and its most important characteristic is equability. And it is plain that a ship lying off a coast enjoys this climate to a greater or lesser degree, in proportion to its distance from the shore.

It has never been laid down at what exact distance from the shore the oceanic climate may be said to begin; but there is every reason to believe that this distance must be very small, whenever, indeed, the influence of the land on radiation, both solar and nocturnal, ceases to be felt.

In another place KELCH and KINNE² fall into JACQUOT's old blunder, for they say:—"This progressive lowering of the death-rate from malaria cannot be attributed to the climate, for that is immutable."

Nor are English writers any more correct when discussing climate, thus DAVIDSON³ in his standard work on "Geographical Pathology" says of the Valley of Amazon, "when the forest has been cleared and the earth disturbed, the character of the climate will become better known." This is unfortunately equivalent to saying, when the climate is altered, we will know what it is like, for as I will have occasion to show later on, forests exercise a most important influence over climate.

But I think I have given enough illustrations to justify anything I have put forward regarding the misuse of this word.

In Ague we have a disease which seems to differ from all other diseases in many ways, and in none more than in this. That it is in the power of man to exercise such complete control over it. We can avoid it, we can cure it, we can exterminate it from haunts where it has long been endemic, and we can produce it in places where it was formerly unknown.

Outside of the domain of diagnosis we really would not want to know very much more about it, if it were not for the fact that the rationale of the methods by which it is either abolished or produced, are either misunderstood, or willfully obscured.

In the course of this paper I will endeavour to point out that *wherever malaria has been either banished or introduced, there has been a coincident change in the local climate, that is, in the climate of the place concerned.*

DRAINAGE.

Of all the methods that man has employed to get rid of Malaria, Drainage holds the first place. I may remark, however, that drainage has its limitations, the colder the climate the more successful it is. In England, Holland, France, etc., it has worked wonders. It has not been so uniformly successful in sub-tropical climates like Algiers; while in equable tropical climates we look for examples of its success in vain.

My present intention, however, is merely to discuss the rationale of the process. In what way does drainage make a marsh healthy? How does it remove malaria? LAVERAN has recently suggested that it does so by exterminating mosquito, but I hardly think this idea is worth discussing.

A great deal has been written on the subject, and the attention of most writers has been concentrated upon the matter of *moisture*. Moisture was one of the factors supposed to be necessary for the propagation of the malarial germ, it was removed, therefore the germ could not flourish; when drainage was neglected, however, it appeared again, and this was explained by TOMMASI CRUDELI* who appears to have been particularly unfortunate in his fanciful speculation, by saying that, "like the seeds of plants the ferment can be dormant in the ground for long intervals."

The idea, then, was that drainage reduced the soil to such a state of dryness that the seeds of plants could not germinate in it.

It is difficult to understand why so much stress has been laid on this matter of moisture. The question is, what is the exact amount of moisture which observations from all points of the globe lead us to believe is necessary for the existence of this supposed germ? and do these accumulated observations lend any support to the idea that this germ is very particular about the amount of moisture that is supplied to it, refusing to thrive unless the quantity lies within certain narrow limits?

Far from this indeed, they point to the opposite conclusion; for we find malaria flourishing under all sorts of conditions and degrees of moisture.

In Senegal, for instance, "the time when most of the country is under water is the time when fever is most prevalent" (DAVIDSON quoting BORIUS); while, on the other hand, it flourishes on the barren shores of the Persian Gulf, (EVATT), "In the bald, arid, and sterile table land of New Castile, one of the most rainless steppes in Europe, and again, upon the tableland of Iran, which lies always under a cloudless sky and bright sun and has no water from natural sources." (HASSON*).

From all this it is plain that moisture does not deserve the important position that has been assigned to it, and that it is impossible to believe that the whole beneficent action of drainage depends upon the fact that some of the moisture has been withdrawn from the soil.

The action of drainage is as little understood by medical authors as the meaning of climate; so we will turn to an agricultural expert and see what he can tell us about drainage.

Mr. D. S. FISH says:—"Drainage, as popularly understood, means the art of laying land dry. This, however, is a very imperfect definition, both of its theoretical principles and practical results. Paradoxical as it may appear, drainage is almost as useful in keeping land moist as in laying it dry. Its proper function is to maintain the soil in the best hygrometrical condition for the development of vegetable life. Drainage has also a powerful influence in altering the texture of soils. It enriches their plant feeding capabilities, elevates their temperature, and improves the general climate of a whole district, by increasing its temperature, and removing unhealthy exhalations. It lays land dry, by removing superfluous water; it keeps it moist by increasing its power of resisting the force of evaporation: " " " It heightens the temperature of the earth, by husbanding its heat, and surrounding it with an envelope of comparatively dry air, and by substituting the air for water withdrawn through the interstices of the soil " " the more porous a soil is, the greater is its power of resisting evaporation. For this reason porous soils are more moist in hot weather than those of a more tenacious character."

In this full and scientific account of the action of drainage there is much food for contemplation. In the first place we see that medical writers have been content with, and have not got beyond the *popular idea* that the purpose of drainage is to dry land. We see that drainage does not dry land, but brings it into the best condition as regards moisture for the germination of seeds. So what becomes of TOMMASI CRUDELI's parallel about seeds lying dormant?

The changes brought about by drainage are complex and comprehensive, the temperature is elevated, the state of the atmosphere modified, life, both animal and vegetable, is metamorphosed, in a word *the climate of the place is changed.*

Thus I have shown that when malaria is exterminated by drainage, there is a coincident change of climate.

Besides drainage there are two recognised methods of making marshes healthy (1) filling them up; (2) converting them into lakes.

French writers describe two methods of filling up, or obliterating marshes, "entassement" or filling up by manual labour, and "colmatage" or filling by deposits of alluvium, either brought by the sea, or by rivers turned from their sources.

Let us see what happens in these cases. The first question is, when a marsh is obliterated, to what level must it be filled up? This requires consideration, for a marsh is an ill-defined condition; for the existence of a marsh it is not necessary that there should be any standing, or rather lying water, any damp place is a marsh; no water need be visible.

For a place to cease to be a marsh it is necessary that the water level should be some distance below the soil level; but what distance?

There are two things which are characteristic of all marshes, which will help in the answering of the question:

one is that the vegetation is rank and luxuriant from excessive moisture, the other is that the atmosphere always contains an excess of moisture which may be seen in the form of mists at night.

The water level then should be sufficiently below the surface to be out of the reach of the roots of the plant life, and also to be unaffected directly by the force of evaporation.

But raising the soil to such a height above the water must obviously have the same effect upon the surrounding atmosphere as the reverse process of lowering the water level by drainage. So that the results upon the local climate are precisely the same in both cases.

The next question is—How can the mere converting of a marsh into a lake affect the local climate? This opens up some very important and interesting points relative to physical phenomena.

The chief difference between a marsh and a lake is the depth of the water.

We have seen, according to BLANDFORD, and the same will be found in every systematic writer on the subject, that certain conditions of the earth's surface exercise a potent influence on climate. Now one of the most important of these conditions is an expanse of water such as a lake.

The *Encyclopædia Britannica*, says:—"The two chief causes which tend to counteract the effects of terrestrial radiation are forests and sheets of water." "deep lakes may be regarded as a source of heat during the winter."

An explanation of the last paragraph will serve to show the whole climatic difference between lakes and marshes. How can deep lakes become a source of heat? The answer is, by abstracting cold.

At sunset the earth rapidly cools, it radiates the heat taken up during the day into space, this is called nocturnal radiation; it varies very much in intensity in different parts of the world, reaching its maximum in the hottest places.

As the earth cools, the air in contact with it cools; it becomes colder than the air further removed; its specific gravity increases and it tends to flow down hill sides to settle at the lowest levels.

If there is a deep lake there, the cold air settles on the surface of the water, by doing so it cools down the surface layer which sinks to the bottom owing to a consequent increase in its specific gravity, leaving another layer of warmer water at the top.

In this way the earth imparts its coldness to the air, the air to the water, and the water conveys it to the bottom of the lake. It is obvious that a shallow marsh cannot act in this way, on the contrary all the cold air collects on its surface and in its neighbourhood, increasing the amount of dew deposited and forming mists.

There is also a marked contrast between the phenomena related to lakes and marshes during the day. There is a wide difference between the action of the sun's rays on land and water, by land the rays are almost completely arrested at the surface, therefore the surface, if bare of vegetation, receives the whole heat. The nature of the soil is of importance, and sand being the worst conductor,

it is on sandy deserts that the heat reaches its maximum.

Where the rays fall on water, the effect is different; the rays penetrate water to the depth of between 500 and 600 feet, the same amount of heat then that the surface of the earth receives is distributed through 500 feet of water. Where the water is shallow, as in a marsh, the rays are arrested at the bottom which rapidly heats and imparts the heat to the water, hence the temperature of shallow water is very much raised and a correspondingly large amount of evaporation takes place.

It is therefore plain that the conversion of a marsh into a deep lake has an important influence on the local climate.

(To be continued.)

A REPLY TO THE ACCUSATION MADE BY MR. LEONARD HILL AGAINST THE HYDERABAD CHLOROFORM COMMISSION. °

BY T. LAUDER BRUNTON, M.D., F.R.S.,

Physician to St. Bartholomew's Hospital, London.

THE action of anæsthetics is of constant interest to the medical public; but the admirable address of Dr. AUGUSTUS WALLER and the other papers read at the Annual Meeting of the British Medical Association have increased the attention which the subject usually excites. For some time back I have been anxious to discuss some questions regarding the causation of death during anæsthesia, especially in relation to the work of the Hyderabad Commission, but the subject is so large and the time at my disposal is so limited that my intention has been postponed from week to week. I now feel that before either discussing the subject or replying to criticism, I must first of all answer certain accusations which have been brought against me by Mr. LEONARD HILL.

In the *British Medical Journal* for 17th April, 1897, a lecture was published by Mr. HILL on the Causation of Chloroform Syncope, and it was favorably noticed in a leading article of the *Journal* for 24th April. In this lecture Mr. HILL not only criticised severely the work and conclusions of the Hyderabad Commission, but he brought against it charges of (1) prejudice, (2) carelessness, (3) ignorance, and (4) incompetence. At the time when Mr. HILL's lecture appeared, the pressure of other engagements made it absolutely impossible for me to do more than write a few lines in the *British Medical Journal* of 1st May, asking readers to suspend their judgment on the question.

Had Mr. HILL been a medical student trying to gain a scientific reputation for himself by trying to detract from that of others, I might have left his accusations unanswered; but Mr. HILL has already gained for himself a name as a scientific worker; he is a lecturer on physiology at the London Hospital; he is Secretary of the

Physiological Society, and the opinions he expressed in his lecture have not only been quoted with approval by a number of subsequent writers, but they were endorsed by a leading article in the *British Medical Journal* of 24th April 1897, and consequently, however disagreeable the task may be to me, I must reply to his charges.

Although nominally directed against the Hyderabad Commission, all these charges, with the exception of the first, are really directed against me personally, for, as Surgeon-Lieutenant-Colonel LAWRIE says in his letter to the *Journal* of 4th September 1897, p. 617:—"The work of the second Commission was directed throughout by Dr. LAUDER BRUNTON." For this work I am, in fact, responsible, and I am ready to admit that for any faults or shortcomings I alone am to blame. The most important deficiency in the research is one to which Mr. LEONARD HILL refers, not in his lecture, but in a letter to the *British Medical Journal* of 31st July 1897, p. 313, where he says that the Commission failed to throw any light on "the causation of those accidental deaths which take place in the primary stage of anaesthesia." These deaths in man are probably due in great measure to fear, anxiety, or other emotional excitement, and may arise from the respiratory and circulatory changes, either caused directly by these emotions or indirectly through the increased susceptibility to shock from pain or suffocation which they produce.

The members of the Commission were quite conscious of this deficiency, and they carefully considered whether it was not their duty to attempt experimentally to produce in animals by causing pain and terror in them, a condition similar to that which may occur in nervous human beings previous to an operation under anaesthetics. They unanimously decided against doing so on the ground that the pain and terror they would have to inflict upon animals in order to produce in them a state at all like that which occurs in exceptionally sensitive human beings would be so great that they did not feel justified in doing the experiments. In coming to the decision to apply the anaesthetics so as to cause neither pain nor terror to the animals, they were perfectly conscious they were excluding two of the most powerful factors of shock from their experiments, and laying themselves open to the charge which Mr. LEONARD HILL brings against the Commission in his letter.

That there are some other deficiencies I am perfectly ready to acknowledge. It would have been advisable to repeat several experiments if we had had time, and it might have been advantageous on several occasions to use other apparatus if it had been available. But there are few, if any, researches which are free from defects, and I hope to show that in that of the Hyderabad Commission there are none of sufficient gravity to warrant the sweeping condemnation Mr. LEONARD HILL has passed upon it. I have no excuse whatever to offer for these deficiencies, except the shortness of time at my disposal. This time was shorter than might at first be supposed. I had less than a fortnight in which to collect apparatus, for though I received notice of Surgeon-Lieutenant-Colonel LAWRIE's proposal a few days before it was published in the *Lancet* on 21st September, yet the P. and O. steamer *Kaiser-I-Hind* left Southampton on 27th Sep-

tember 1897, and luggage had to be on board a few days before. I reached Hyderabad on the evening of 21st October and the Commission began work without apparatus on 23rd October, with apparatus on the 25th, and continued until 18th December. I had *carte blanche* from the Nizam's Government with regard to instruments, and with the aid of my friend, the late Professor ROY, I collected quickly together all the apparatus which I thought would be requisite. I had in all, however, less than a fortnight in which to collect the equipment of a laboratory, four days in which to fit it up and, Sundays being excluded, forty-seven days in which to do the work with apparatus. But with the exception of time, nothing was left to be desired. The generosity of the Nizam, the intelligent interest taken both by himself and his Ministers in the work, the courtesy and zeal of Surgeon-Lieutenant-Colonel LAWRIE, as well as of everyone connected with the Commission, afforded every possible assistance in carrying out the work. In his letter to the *Lancet* of 21st September 1897, Surgeon-Lieutenant-Colonel LAWRIE undertook to place the Hyderabad Commission entirely at the disposal of the representative of the *Lancet*, and to act under his direction. The Commission, he said, "will provide all instruments and appliances, and everything which may be required for the experiments, and will, without bias, do all in their power to assist the representative of the *Lancet* in arriving at the truth." This promise Surgeon-Lieutenant-Colonel LAWRIE loyally carried out. He placed everything at my disposal, so that (1) I drew up the general plan of the research, and (2) stated what experiments I thought were necessary; (3) I did the first one or more of every set of experiments myself; and (4) I was present and superintended all the experiments till near the end of the research, when I was obliged to be absent for some time owing to an attack of dysentery. I am therefore personally wholly responsible not only for the plan of the research in general, but for the plan of each experiment in particular and for the execution or supervision of each experiment, as well as jointly responsible with my colleagues for the general conclusions. Having now shown how it is that Mr. HILL's accusations, although nominally directed against the Hyderabad Commission, are really made against me personally, I shall take them up and answer them *seriatim*.

His first accusation is that of prejudice, and of a desire on the part of the Commission to prove the correctness of a preformed conclusion, instead of trying to find out the truth. He says on page 957, "The prejudiced enthusiasm of Surgeon-Lieutenant-Colonel LAWRIE," and page 960, "The Hyderabad Commission engaged on a wild goose chase to prove that respiration ceases before the heart fails, find in their tracings the proof that the failure of respiration is the primary cause of death. I, on the other hand, maintain that not only my own tracings but theirs too, conclusively prove that failure of circulation is the primary cause of the failure of the respiratory centre."

The first part of those quotations is directed personally against Surgeon-Lieutenant-Colonel LAWRIE, but in the second Mr. HILL attacks us both. Now, whatever the views of LAWRIE may have been, my own decided view, when I went out, was that stoppage of the heart was

certainly one of the dangers to be apprehended from chloroform anaesthesia. Nearly twenty-five years ago, I was accustomed to show to my class an experiment by which a current of air from the same bellows was divided by a Y tube into two equal parts, one of which passed through chloroform into the trachea of one animal while the other passed through ether into the trachea of another similar animal. Both animals were thus thoroughly anaesthetised, and the movements of the heart in each were made visible to the class by a needle, to which a long straw bearing a flag at the top was attached. When the anaesthetic was pushed by working the bellows rapidly, the heart of the chloroformed animal was quickly stopped, while that of the etherised animal went on beating with hardly any change. In a paper on "One of the Causes of Death during the Extraction of Teeth under Chloroform," *British Medical Journal*, 4th December 1874, I had also expressed the opinion that syncope from failure of the circulation was one of the causes of death during chloroform anaesthesia.

In my *Experimental Investigation of the Action of Medicines*, Appendix, p. iv, I said:—"In operations on the abdominal viscera in dogs, for example in making gastric fistulae, death sometimes occurs from shock, although the animals are completely under the influence of chloroform. For such operations ether is preferable, as it increases rather than diminishes the power of the heart."

My own expectation, therefore, was that we should find syncope from failure of the heart and circulation to be a powerful factor in death during chloroform anaesthesia, and the first experiment with a manometer made by the Commission on 25th October was on the effects of various operations likely to produce shock. To the evidence which led me to alter my views, I will afterwards refer, but I think that the following annotation from the *Lancet*, 7th December 1889, p. 1183, shows that I did not go out on a wild goose chase to prove that the respiration ceases before the heart fails, and that this accusation of Mr. HILL is unfounded.

We have just received from Dr. LAUDER BRUNTON the following telegram, which we print *verbatim*—"Four hundred and ninety dogs, horses, monkeys, goats, cats, and rabbits used. One hundred and twenty with manometer. All records photographed. Numerous observations on every individual animal. Results most instructive. Danger from chloroform is asphyxia or overdose: none whatever heart direct." "These results apparently indicate such a complete reversal of the view held by Dr. LAUDER BRUNTON at the time he left England—that one of the dangers resulting from chloroform is death by stoppage of the heart—that the details of the experiments made by Dr. BRUNTON, and the reasons for the conclusions he has evidently arrived at, will be awaited with the greatest interest by the profession."

The second accusation brought by Mr. LEONARD HILL is that of carelessness. He says "upheld by a series of experiments, many so careless in execution that they could not for one moment be accepted by a trained physiologist." This sweeping statement of Mr. HILL's practically condemns every experiment of the Hyderabad Commission, for he does not specify those to which the condemnation applies, and in the absence of such specification his condemnation may apply to all. It appears to me that Mr. HILL, in bringing such a sweeping accusation against the Commission, was bound to support it by reference to definite experiments, and I now call upon

him to adduce his evidence. "I have looked through Mr. HILL's paper carefully, but the only evidence which I find he brings forward of carelessness is that of the imperfect application of electrodes to the vagus. Just at the time when I began to direct my own attention chiefly to the supervision of the mercurial kymograph, and to delegate to Mr. CHAMARETTE the task of introducing cannulae in the arteries and veins, or of exposing and irritating the vagi, the experiments were not always completely successful. Thus in No. 68 the introduction of the cannula was not accomplished without damaging the artery, and the vagus was not rightly exposed, but on every occasion where we had the least reason to suspect any imperfection in the experiment—for example, in experiment No. 95, where there was a doubt whether the vagus had been rightly stimulated—such imperfection was carefully recorded in order that it should not mislead either ourselves or others in the interpretation of our experiments. With the exceptions which the Commission carefully recorded, the experiments were done with the greatest care, and unless Mr. HILL can bring forward more definite evidence to support his assertion that many of the experiments were so careless in execution that they could not for one moment be accepted by a trained physiologist, I believe that every physiologist will decide that his accusation is unwarranted.

In regard to the cases of accidental death, Mr. HILL draws a comparison between the carelessness of which he accuses the Commission and his own accuracy, for, as he tells us, in all cases of chloroform syncope occurring during primary anaesthetisation he carefully observed the symptoms. The Chloroform Commission carefully observed the symptoms in a much larger number of cases than Mr. HILL, but when deaths occurred during careful observation they were not classed as accidental. I still fail to see how Mr. HILL could properly class his cases as accidental if he was observing them all the time. One of the accidental deaths occurred while I was performing tracheotomy upon an animal, and was of course in a favorable position for observing its respiration, but my attention was concentrated upon the operation, and I failed to notice the failure in respiration until too late. This may no doubt be put down to carelessness upon my part, but it was just such instances of carelessness which form one of the most valuable parts of the report as tending to throw light upon the causes of so-called accidental death occurring in actual practice.

Thirdly, I shall now take up Mr. LEONARD HILL's charge of ignorance of physiological methods. Considering that I have been trained by BRÜCKE, ROSENTHAL, KUHNE and LUDWIG, this charge seems *a priori* improbable; but such training does not disprove Mr. HILL's charge. I will therefore take the instances which he brings forward. He says:—"The Hyderabad Commission failed to obtain this effect, although they injected 20 c. cm. of pure chloroform into the jugular vein in successive doses. The cause of this failure is to be found in the ignorance of precise physiological methods which was unfortunately betrayed throughout much of the work of the Commission." Mr. HILL states that in our experiments the drug remained in the veins. If this statement of his were true, the chloroform ought not to

have produced either narcosis or death as it did. He admits the fact that we injected the chloroform into the jugular vein, after ligation as one evidence of my want of knowledge of exact physiological methods. I have many times injected drugs into the veins of animals in which the blood was freely circulating, but the advantages of this method do not, I think, counterbalance its defects. Mr. HILL may think that this is a mere opinion of mine founded on ignorant stupidity or prejudice, but some eminent physiologists have come to the same conclusion as myself. The method I employed is the one described by BURDON SANDERSON in his *Hand-book for the Physiological Laboratory*, p. 238; by CLAUDE BERNARD in his *Leçons de Physiologie Expérimentale*, p. 262; by CYON in his *Methodik der physiologischen Experimente*, pp. 49 and 50; and by GACHEIDLEN in his *Physiologische Methodik*, p. 538. It is true that CLAUDE BERNARD describes the method of intravenous injection which Mr. HILL regards as the only proper one, but the only advantages which he attributes to it is that of simplicity. LIVION, who reproduces BERNARD's figures and also describes both methods, mentions the advisability of having a ligature round the vein in order to prevent possible bleeding. As the two latter authors describe both methods they may be absolved from ignorance, but as BURDON SANDERSON, CYON, and GACHEIDLEN all recommend the method which I adopted, they must all necessarily fall with me under Mr. LEONARD HILL's condemnation of being ignorant of physiological methods.

Besides ignorance of exact physiological methods Mr. HILL accuses me of incapacity to interpret aright the tracings of the blood pressure which the Commission obtained. I have already admitted that I am responsible for the interpretation of the tracings, so this accusation of Mr. HILL's is brought against me even more directly than the others. He says—"Now on examining the tracings of the Hyderabad Commission I find an absolute agreement between their results and my own. . . . Although the tracings are so much alike, the interpretations are widely different. The Hyderabad Commission engaged on a wild goose chase to prove that respiration ceases before the heart fails, find in their tracings the proof that the failure of respiration is the primary cause of death. I, on the other hand, maintain that not only my own tracings but theirs too, conclusively prove that the failure of circulation is the primary cause of the failure of the respiratory centre." From this statement I think any unprejudiced reader would infer that it was upon their tracings that the Hyderabad Commission relied for proof that failure of respiration is the primary cause of death, but this was not the case. The proof that failure of respiration is the primary cause of death from chloroform narcosis consisted in the fact that 141 animals were chloroformed to death by the first Commission, and 480 by the second, and in every one of these 571 animals the respiration failed before the heart. It was evidence of this sort that led me to modify my views regarding the risk to the heart by the action of chloroform directly upon it.

A similar charge of inability to interpret the tracings correctly was brought against me by Drs. GASKELL and SKEAN, who say regarding the Hyderabad Commission:

"Their large number of curves confirm again and again the observation of others, and point to heart failure as the cause of the fall of blood pressure."

In his letter of 31st, July 1897, Mr. HILL says:—"The truth which I seek to establish is that chloroform kills by primarily paralyzing the whole of the vascular mechanism." But in his lecture of 17th, April 1897, it is upon the paralysis of the vessels that he lays most stress. A comparison between Mr. HILL's lecture and the above quotation from Drs. GASKELL and SKEAN, will, I think, show how just was the conclusion arrived at by the Hyderabad Commission in the interpretation of the curves we obtained; for, as I pointed out, "it was precisely because the second Hyderabad Commission, when going over their experiments, thought that although their results indicated paralysis of the vaso-motor centre as a cause of the fall in blood pressure, yet the evidence before them was not conclusive that they did not formulate any conclusion on the subject." They left it as a point to be decided by further research.

To one statement made by the Hyderabad Commission, Mr. LEONARD HILL says that he "must give a direct denial." This statement is to the effect that inhalation of chloroform has no effect on the length of the period in which the heart can be maintained in arrest by electrical excitation of the vagus. One would have thought that only an intense feeling of duty would have led Mr. LEONARD HILL to the use of such language, yet later on he states that while he has "been able to kill animals by repeated and prolonged vagal arrest of the heart, such complete vagal arrest of the heart is never induced by chloroform, and therefore these experiments are of no clinical interest."

Fourthly, the last accusation may be regarded as one either of ignorance or carelessness, for he does not say which it is; but had his account been accurate, Mr. HILL would have been perfectly justified in condemning me as incompetent. He says "The Hyderabad Commission carried out a few experiments on the effect of the alteration of the position during chloroform narcosis. The workers paid no attention to the fact of the absolute necessity of placing the arterial cannula in the axis around which the animal is turned. Their experiments were thus vitiated by the hydrostatic effect of gravity on the column of fluid in the tube which connected the cannula with the manometer. By the neglect of such a simple precaution the experiments on this point were rendered entirely worthless." I have sometimes felt inclined to ridicule the strong language in which some foreign writers, and especially very young ones, criticise each other's work and denounce each other's statements as absolutely false, and to rejoice that scientific literature in this country was free from this blemish. In his lecture Mr. HILL met one statement of the Hyderabad Chloroform Commission with a flat denial where, perhaps, less strong language might have been admissible, but I little thought it would be my own lot to use the expression "absolutely false" in relation to any statement contained in a scientific paper, yet there is no other by which I can characterise Mr. LEONARD HILL's statement, for it is without the slightest foundation in fact. When I read it I thought that it must be a misprint, and that he meant to say that we

had paid no attention to having the axis round which we turned the animal pass through the indifferent point in its vascular system, which, as HERNAN and his scholars BLUMBERG¹⁰ and WAGNER¹¹ have shown, passes through the apex of the heart. Had this been the objection raised by Mr. HILL to our experiments, it would have involved a matter of opinion, and something might have been said on both sides. But his statement involves a matter of fact, and not of opinion, and as such it can only be met by an absolute denial. The precaution which he says was not taken by the Hyderabad Commission was taken most carefully. For knowing the fallacy to which he refers, I made it my own special charge to see that (1) the cannula in the carotid, (2) the axis upon which we turned the animal, and (3) the horizontal limb of the manometer, were in the same horizontal plane, or, in other words, were at the same level, and remained so throughout the experiment. I cannot think that Mr. LEONARD HILL would publish a falsehood wilfully, but a falsehood his statement certainly is and I shall be curious to learn how he has been led to make it.

I now leave it to the "trained physiologists," whose mouth-piece Mr. LEONARD HILL has constituted himself, as well as to the whole medical profession, to decide whether the evidence that Mr. HILL has brought forward is sufficient to justify the charges of (1) prejudice, (2) carelessness, (3) ignorance, and (4) incompetence, which he has brought nominally against the Hyderabad Chloroform Commission, but really against me personally.

OBSERVATIONS ON EPIDEMICS OF CHOLERA IN INDIA WITH SPECIAL REFERENCE TO THEIR IMMEDIATE CONNECTION WITH PILGRIMAGE.

By CHARLES BANKS, M.D., D.P.H.

Late Civil Medical Officer, Puri.

FERTILE Orissa, with her 944,988 souls scattered over 2,473 square miles, is to India what Jerusalem was to the descendants of JACOB. Few indeed of these people who profess other than Hinduism and yet 28,794 are concentrated inside of three square miles of sacred ground which contains the famous temple of Jagannath. This little place, which is situated in the south-eastern corner of Orissa and is only 300 miles from Calcutta, is call Puri, more reverently known as "Juggernath," whither for many hundreds of years thousands of religious devotees have yearly flocked in an almost endless stream to worship at the shrine of Jagannath, or take part in the *jatras* for which this holy city is famous, and of which the most important are the Dolejatra (swing festival in March), the Râthjatra (oost festival in June or July) and the Panchak or five-days festival in October or November.

Some idea of the magnitude of these assemblies will be afforded, by the fact that during June 1893, no less than 200,000 pilgrims thronged together at Puri to witness the expected reincarnation of their god Jagannath, and simply more than overcrowd the town itself as well as the halting stations along the whole length of pilgrim routes.

Every religious devotee has to bathe before he cooks his food or engages in worship, but as he is not over particular as to how close to the source of water supply he deposits his effete matter, whether liquid or solid, the wells and tanks become fearfully fouled and there is little, if anything, in the shape of conservancy arrangements.

Tired and famished with the day's march, these pilgrims frequent the route bazaars to purchase their food supplies, which are not always of the best, and the wily bannîâh has no compunction in passing off damaged grain, &c., on travellers who must take what they can get or starve.

Mile after weary mile is trudged in bodily fatigue on an ill-fed stomach till they arrive at their destination when they make up for lost time by feasting greedily on the piles of rich viands the Brahmins have cooked for them. These and other things combine to render beautiful Puri, with her magnificent temples and thrice sacred shrines, a veritable plague spot, the valley of death, a pest-house whence streams of disease constantly issue and the ever open grave of crowds and crowds of pilgrims, much the greater number of whom are superstitious females who are far more easily induced than are the males or terrorised too readily by pilgrim hunters who scour the country, dilating upon the blessings without number to be gained by bowing before Jagannath's throne at Puri and depicting the hideous torments to be meted out to such as will not visit the holy city, even though they are physically unfit to endure the fatigue and depressing influences of long and tedious marches, and are notably more ignorant and regardless of the consequences of disobeying the ordinary laws of health. This is one set of reasons why females are so prone to contract the disease, and it is a general opinion in Orissa that cholera of a severe type only appears when low-caste Bengalee pilgrims are in the majority, and that the disease seldom breaks out or attains serious dimensions amongst up-country people who are of stronger physique and cleanly in their habits—opinions to which close observation warrants professional subscription.

True, cholera may occur simultaneously and at a considerable distance from pilgrim routes; but careful investigation will, in the majority of instances, trace the primary cause to arrival of cholera-stricken pilgrims, or to a member of the village returning home already suffering, or who had been exposed to the disease prevailing amongst pilgrims along pilgrim routes and attacked on his arrival.

Considering the very large areas over which Civil Surgeons exercise control, and the impossibility of immediately proceeding to the 'place of outbreak,' in every instance, it is much more difficult in India, than in most countries in the world, to arrive at definite conclusions regarding the progress and other points in the history of epidemics.

Comparing the cholera mortality of 1893, when 200,000 pilgrims assembled at Puri with that of 1894, we learn some curious facts re the importation of the disease.

	Total Deaths.		Among pilgrims.	
	1893.	1894.	1893.	1894.
Puri Town ...	271	109	245	75
Sadar Circle ...	522	517	310	496
Pipli Circle ...	610	715	333	636
Khurda Circle ...	165	234	98	510
Gopa Circle ...	188	24	8	24
Banpur Circle ...	12	2	8	2

Or, in other words, that of 3,462 victims claimed by cholera in those two years no less than 2533 were carried off between July and August, when the car festival was at its height. It was also noticeable that while in 1894 the epidemic starting with a *female pilgrim* on the 2nd July increased in virulence till the 9th *idem*, when with the efflux of pilgrims it began to abate and altogether ceased on the 13th August, by which time *all* the pilgrims had departed for their homes. These facts coupled with the comparatively small death-rate from cholera in the Banpur and Gope districts, which with their 697 square miles and 229,257 inhabitants are not in the direct line of pilgrim traffic, go to show how exclusively the cholera epidemics confined themselves to pilgrim routes. To this evidence add that adduced by the second epidemic of 1894, which was ushered in by four *female pilgrims* on the 6th October and remained till the 20th November, by which time it accounted for 101 deaths out of 135 cases in Puri alone.

The points of special interest in connection with the second epidemic were :—(1). It somewhat abated from 16th to 21st October, when it was reawakened to violent action by some pilgrims landed at Cuttack by the steamer *Balaram*, and one of whom was picked up on the Cuttack-Puri road in a dying condition. (2). From the 1st to 8th November was another lull with only four cases, but on the 9th November, which was the first day of the Panchak festival, the number of pilgrims increased, and by the 13th *idem* there were 15 more cholera victims, while from the 14th to 20th November there were 9 cases and no more to the end of the year. (3) During the month of Kartick (October-November) most of the residents of Puri increase their sanctity by fasting the whole day and at night only eating *mohraprasad*, i.e., rice cooked in the temple of Jagannath. The last five days of Kartick constitute the Panchak, and it is very striking that the epidemic increased in intensity during this period.

Wherever rapid communication and a comfortable mode (as at Gaya, not Puri) of conveyance occur along pilgrim roads, cholera decreases and does not spread to the people generally. Whatever may be the case with other parts of India, there is abundant and conclusive evidence, so far as Puri is concerned, that cholera is invariably imported, and outbreaks of this disease in district villages can, without exception, be distinctly traced to pilgrims or travellers along pilgrim routes. So inseparably are cholera and pilgrimages connected, that to prevent the former the latter must be put a stop to, and so long as pilgrimages are tolerated or are considered so essential by the Indian native community from a religious point of view, so long will the death-rate from cholera remain high—and that, too, in spite of climatic or other conditions.

Bristow says :—"The duration of the incubative stage of cholera is not certainly known. It probably varies generally between a few hours and three days." The Vienna delegates think it "did not last beyond a few days," and Dr. E. A. PARKES finds that it can certainly last for 10 or 12 days, and there are some cases on record where it lasted for more than 20 days;" but Dr. MACHA-

NARA gives instances where incubation took place within 48 hours after exposure to the cholera infection. The writer however, had several cases where incubation was 48 hours, and declares he never came across a case in which there was a single fact pointing to a longer period than three days after importation of the disease, and in the majority of cases the period appears to be well under three days.

Wherever discipline with cleanliness and disinfection can be enforced as in the Puri Municipal and Government hospitals, the direct communication of the disease is rare, if not impossible, and the writer has seen but three instances, in two years, in which it was probable that the disease was communicated to healthy individuals directly :—(1). A father attended his sick son in the Puri cholera hospital, the son recovered; but the father took ill and died. (2). A sweeper engaged in cremating cholera corpses was attacked with the disease and died. (3). To avoid handling the dejects 382 Municipal latrine sweepers used long-handled coconut-shell ladles to scrape up the night soil. They were also careful to wash their hands and bodies before partaking of food. One of their number, a girl who assisted her mother in cleaning latrines during a cholera epidemic, contracted the disease and died. On the other hand, not one of the officials or many underlings in any of the different hospitals in which cholera cases were treated showed any symptoms of the disease.

It may also be safely assumed that the disease is not at all communicable through the atmosphere, or if so, to a very inappreciable extent. Five instances are recorded of air-borne cholera, but as most of the cases cited happened 50 years ago, when less was known about the disease and its contagious properties; or how the contagion spread, they must be accepted with a certain amount of caution.

Fear of contracting the disease may give rise to symptoms of a choleraic nature. While visiting the Puri Cholera Hospital at a time when it was full of patients, the acting Chaplain of Cuttack—a fresh arrival in India—clearly showed, by standing with his back to the building and his face seawards, that he did not feel quite at home. That evening he had diarrhoea and vomiting that lasted the whole night and part of next day, after which no other symptom manifested itself. The air of cholera hospitals or sheds may even smell to an unbearable extent without giving rise to cholera among attendants on the sick, who not only live in but also sleep in them.

Whether meteorology exerts any direct influence on the spread of cholera or not is difficult to definitely say, but it is worthy of note that although a greater number of persons died in 1893 than in 1894, still the death-rate was vastly less since a much greater number of pilgrims assembled in 1893 than in the latter year. This fortunate result was attributed to the abundance of the rainfall in 1893, tending to check the dissemination of the disease and to cut short the duration of epidemic outbreaks. The disease prevailed chiefly during periods of scanty rainfall accompanied by a high temperature of the atmosphere.

In 1894, however, the rainfall seems to have had a precisely opposite effect, and the temperature of the atmosphere did not seem to enter, to any appreciable degree,

into the cessation of the two epidemics which occurred in 1894.

In February and March 1894, cholera appeared to follow dark, gloomy and cloudy weather, but no case of the disease was reported between 5th April and 29th May, although the temperature continued unusually high. Again there was no cholera in June, the early part of which was composed of duststorms, sultry or dark gloomy weather, and passing showers, but towards the end of the month there was thunder, lightning and heavy rain, forcing up the subsoil water level and flooding the tanks, road-side ditches (that answer for drains) and pools.

On 3rd July 1894 came the first batch of Rathjattrā pilgrims, and with them seven cases of cholera, which began its epidemic rôle, which it kept going strongly till the 1st August, when with a decrease in the rainfall the disease began to abate and altogether ceased by the 13th August, although these thirteen days were much hotter than July.

On the 6th October, which ushered in the second epidemic lasting to 28th November, the pilgrims were again on the march to Puri, and 8.88 inches of rain (of the 13.32 inches rainfall for the entire month) fell on that day alone. The death-roll began to abate on 16th November, which was six days after the cessation of the rains, and from 16th to 28th November there were only 9 cases of cholera, while from the 28th November, when the town and district of Puri were practically pilgrimless and there were no more fresh arrivals of devotees, there was no more cholera.

From due consideration of all these points, it is reasonable to suppose that temperature could not have played as important a part in the causation of the epidemic as that provoked by the rainfall, and it becomes evident that whatever part meteorological conditions play in causing or otherwise influencing cholera epidemics, pilgrimages in themselves are mainly responsible for the greatest share of exciting causes, and it is more than probable that cholera and pilgrimages are intimately and inseparably associated with each other.

Whether the comma bacillus is the essential agent in the production of cholera or whether it is one of the minor conditions evoked by that disease are vexed questions over which the scientific world is still wrangling, but no matter what may ultimately be found to be beyond question the specific cause, it cannot be denied that cases do occasionally crop up in which it would be indeed difficult to believe that any specific virus could have been the prime causative agent; and the whole of the 1,419 cases

that occurred in Puri and its direct neighbourhood in 1893 and 1894, go to show the intimate connection with unwholesome food consumed by the patient.

During long marches, specially in wet weather, pilgrims subsist on parched rice (choora or masur), raw vegetables (cucumbers largely), unripe or over-ripe fruits and sweetmeats of every conceivable variety, containing a liberal admixture of fat, decomposed ghee or adulterated oil. Other cases show a period of starvation followed by gormandizing-bad food bought at the lowest possible price and proving fatal, accompanied with symptoms between which and those of true cholera, whose diagnostic feature is Koch's bacillus, the line of demarcation would indeed be a very fine one.

Though in the absence of a bacteriological examination it could not be positively asserted that the comma bacillus did not cause such cases, still the circumstances under which they occur are so strikingly peculiar and mysterious that one might positively affirm that this organism could not have caused them. These cases, relegated to the category of ptomaine poisoning are almost as deadly as cholera, used in its main meaning, although, perhaps, not equally if at all contagious.

The fact also that the great majority of the cases occur in the night or very early in the morning induces to the belief so strong rooted in the Indian mind, whether lay or medical, that food receives a prominent and water a very undignified position in the etiology of this disease.

Village tanks, without exception, are so foul that where well water can be had for drinking purposes the tanks are reserved for bathing and washing clothes; but as in many villages in the Puri district there are no wells, the tanks supply the water for drinking and cooking, and it is a singular fact that not only are such villages most severely attacked, but also that ever since they had an existence cholera has seldom or never been absent from them: same also in every other place in India, where tanks afford the only water supply; but, as a rule, not where well-water is provided for and used by the people, and those members of such communities who show a preference for tank-water, whether for drinking and cooking or for the cleansing of their teeth and tongue are the chief sufferers during village epidemics of cholera, since the idea of germs of disease clinging to their teeth, tongue or palate or of being taken direct into their stomach, is foreign to their nature.

Pilgrims, as a rule, are absolutely indifferent as to the nature of the water they drink; and when hot and thirsty, rush for the nearest supply they can find, whether in a tank, pool, well, ditch, or buffalo-wallow.

Many eminent bacteriologists dispute on scientific grounds: (1) That all the distinct forms of comma bacilli are mere varieties of one species. (2) Cholera occurs without the presence of comma bacilli of any kind. (3) If cholera can be caused by organisms growing in the intestinal tract, these have yet to be found. (4) Comma bacilli are the consequences and not the cause of the disease, but grant that even if the consequences, they may give rise to products that may become absorbed when the active condition of the intestine is re-established and thereby affect the ultimate course of the disease.

The question, if not the whole, of the Puri cases coming under the probability of having been caused by premises belonging to the class in which bacteriological evidence there is no evidence of the presence of common bacilli, and it is clear that a district such as Puri affords a wide field for exhaustive bacteriological investigation during severe and extensive outbreaks, and in all cases which occur in sporadic form at what may be regarded as seasons unfavorable to the growth of the germs; but the investigator must not be handicapped, as was the writer of this thesis with a multiplicity of other important duties, and want of suitable equipment.

Though neither pilgrims nor natives of any district deposite directly into tanks or wells, they have the highly objectionable habit of defecating in close proximity or on the margins and sides of tanks and ditches or of entering the water for ablution purposes immediately after the act of defecation has been performed. The roadsides of pilgrim routes are literally converted into continuous latrines, and during the rains the very nature of the roads affords the greatest possible facility to both solid and liquid excreta, among which are cholera dejecta, being washed into the ditches, the contents of which pilgrims drink with as much relish as the purest water.

It is a striking fact that the disease can be checked in a remarkable degree in those towns where ditch water cannot be had for drinking purposes, or where tanks and wells are protected against pollution.

But it is still more striking that prevention of well or tank pollution by wholesale destruction of soiled clothing, and prompt disinfection of the first affected houses has nipped cholera in the bud.

Whatever the etiology of cholera in other districts of Bengal, in Puri at least it is due to neither more nor less than the introduction of fresh choleraic discharges coupled perhaps with the excessive amount of ordinary human and animal refuse and mineral matters that directly enter or are washed into the water contained in tanks, pools, wells and ditches, and that the intensity of cholera epidemics depends on the quantity of water contained in them and the degree of concentration of such refuse since it can not be denied that cholera discharges are contagious.

Although no specific has as yet been discovered, and almost every remedy that has been recommended has been tried in the hospitals and found of no avail in the treatment of cholera, still in its earlier stages the disease is amenable to treatment, and the success which has attended astringents to begin with, and the avoidance of opium in the more advanced stages of the disease, coupled with the extra exhibition in proper time of stimulants and nourishment in suitable quantity and quality, warrant us in discarding eliminative treatment.

The general conclusions derived from the foregoing observations are:—(1) Pilgrimages and human intercommunication generally are most powerful factors in the dissemination of cholera, which (2) is inseparably connected with pilgrimages and confines itself for most part to pilgrim routes. (3) That water is undoubtedly the chief vehicle through which the germs of this disease are introduced into the human system. (4) That cholera, if at all communicable through the atmosphere, can only be so communicated to an almost inappreciable extent. (5) That when attendants on the sick are attacked, the unfortunate occurrence must be ascribed to negligence with regard to cleanliness and disinfection of the hands before partaking of food. (6) That the dissemination of the disease can be prevented by suitable precautions. (7) That in the majority, if not all, of the cases the period of incubation is well under three days from the actual time of ingesting the virus. (8).

That quarantine during pilgrimages is impracticable and dangerous; but that isolation is one of the most important preventive measures. (9) In its incipient stage cholera is amenable to treatment in most instances.

INDIGENOUS DRUGS OF INDIA: TAJKARNATI OR CINCHONA EXCELSA.

BY R. P. BANERJI, B.A., G.S.M.S.L.

Salt Works, Pachbadra, Rajputana.

The *Hymenodictyon Excelsum* (Wallich), or *Cinchona Excelsa* (Roxb), which belongs to the Rubiaceae is a native of the mountainous districts of the Madras Presidency, where, under the name of *Taj Karnati*, it flourishes as a large and very umbellaceous tree with a straight, thick trunk with numerous spreading branches and covered with thick anserous, deeply excoriated pale brown bark, whose inside is reddish brown but whitens with age. The leaves which depend their smooth or slightly fleshy surfaces from interpetiolar stipules, are oblong, petiolated opposite, stipulate and sometimes verruculose. The flowers appear copiously during the rains as fragrant bracteate terminal panicles of a pale green color. The polysepalous (5), epigynous toothed calyx carries an epigynous, five-petalled gamopetalous funnel-shaped corolla with a pubescent surface and long tube, from whence spring five epipetalous stamens with short thick filaments and exserted erect jointed anthers. The single pistil with its long exserted style and clubbed stigma surmounts an oval ovary, situated in a kind of receptacle.

The fruit, which ripen late in the winter months, occur as dry, oblong capsules opening at the top to which the dried calyx adheres. The imbricated compressed seeds, which are found in multiples of three, are slightly winged and the embryo is erect and albuminous.

The wood, which is hard and close-grained, takes a beautiful polish. All parts of the tree are fairly rich in tannin and impart a persistent bitter taste to water, when infused in it, but the bitterness is not so intense as that of cinchona bark.

The dried bark of the young tree is officinal; but great care must be taken in the drying, since damp readily mildews the inner surface and deteriorates its therapeutic effect.

Native medical practitioners claim it has powerful antibilious, tonic and febrifuge properties, whether alone or in combination with other drugs, and the large demand for it by hundreds of Indians, who are averse to European medicines, has led to its being adulterated with, or fraudulently substituted by, cassia bark, surinjan taj, faded cinnamon bark, &c.

I have not been able to give the bark a very extensive trial; but in the few cases I treated with it, I found that its decoction was well borne by persons, who could not tolerate quinine or cinchona, and that it gave excellent results as a bitter tonic for weak or debilitated persons and in habitual constipation, while it was unsurpassed as an antibilious remedy and febrifuge.

As a bracing tonic I prefer giving from $\frac{3j}$ to $\frac{5jv}$ thrice daily (children $\frac{1}{2}$ doses) of a compound decoction made by mixing:—Powdered *Hymenodictyon* bark, dried Baal pulp, *Ptychotis Ajwain*, as $\frac{3jv}$, Ginger and Coriander seeds, freed from husk, as $\frac{3j}$ and Licuorice root $\frac{3vj}$ with $\frac{1}{2}$ quart of water and boiling till the water loses half its bulk, when it should be strained, allowed to cool and bottled off for use.

Under its use the (1) skin spots freely, (2) functional disorders of the womb were fully amended, (3) chronic fever and bronchitis were particularly benefited, (4) and so also habitual constipation and biliousness (5) while during convalescence its bracing effects were particularly well marked.

A MIRROR OF PRACTICE.

NOTES ON GUNSHOT WOUNDS.*

By SURGEON-CAPTAIN J. M. CRAWFORD, I. M. S.

Base Hospital, Nowshera, North-West Frontier of India.

SIXTY-TWO cases of the gunshot wounds received in the attack on the Malakand on 26th, July 1897, and in the operations immediately following it were transferred to the Base Hospital for native troops at Nowshera for treatment. Nowshera is forty-eight miles from the Malakand, the journey being covered in four marches, the intervening camps being Hoti-Mardan, Jalala, and Dargai, at each of which a section of a field hospital with an I. M. S. officer was stationed, the sick being transferred from the front in ambulance tongas and dhoolies.

Five of the British infantry barracks at Nowshera, each to accommodate 75 men have been set apart for the base hospital for native troops, additional accommodation for the milder cases being provided in "European privates" tents, each of which accommodates 8 sepoya.

On the date of writing (21st, October 1897), 4 out of the 62 cases have died; 10 are still remaining under treatment in the Base Hospital, all of which, with 1 exception, are convalescent; 7 have been sent back to their respective corps at the front; 9 have been sent to their regimental depots for duty, not being considered fit for the extra hard strain of field service; and 32 have been sent on sick leave to their homes. These latter consisted largely of cases having some stiffness in the muscles or joints, the result of being laid up in splints, and which merely required slight passive movements and time to complete their cure.

The first cases were received in the base hospital on 16th, August and more were sent down from the front from time to time, as the condition of their wounds and the amount of available transport admitted. The main characteristics of the wounds were those which would have been caused by non-explosive projectiles, namely, there was not a very marked difference between entrance and exit wounds, very little splintering or shattering of the bones, and an absence of injury to the soft tissues and unimportant structures in the immediate vicinity of the track of the bullet, all of which point to a non-explosive projectile and a comparatively low velocity.

The general good health of the wounded, the absence of tetanus and septicæmia, and the small mortality, all point to the care with which antiseptic treatment at the front had been carried out, as well as to the good hygienic surroundings of the wounded in the base hospital. Of the 4 fatal cases, 1 died of fever (probably malarial), 2 from hectic fever and 1 from gangrene, the result of injuries in the region of the axillary artery.

Appended is a tabular statement giving a rough classi-

*Reproduced from the *British Medical Journal* by request.

fication of the injuries treated, together with brief notes on four of the more interesting cases:—

* Implication of knee-joint in one case.

† Impliable of ankle-joint in one case.

‡ Implication of shoulder-joint in one case.

§ Secondary amputation.

1. Sepoy U. B., 31st Punjab Infantry, aged 30. Service seven years. Wounded at Malakand on 30th, July and admitted here on 17th August. This man was wounded by two bullets: (1) the bullet entered the inner side of the right thigh, 3 inches above the internal condyle of the femur, and came out at the inner and back surface of the knee, it then re-entered the calf of the leg, and passing between the tibia and fibula, had its exit close to the ankle on the outer side of the leg. The man was kneeling on his right knee when hit. (2) The other bullet, after grazing the inner condyle of the right elbow, entered the body 4 inches above the posterior superior spine of the right ilium and travelling under the skin, came out 3 inches posterior to the wound of entrance. Both wounds were simple flesh wounds. He was discharged from hospital, and sent on four months' sick leave on 11th, October as there was some stiffness of the leg remaining.

2. Sepoy B., 31st Punjab Infantry, aged 29. Service ten years. Wounded at Malakand on 28th July and admitted to Base Hospital, Nowshera, on 18th August. The bullet entered the right arm just below the coracoid process, and passed out close to the axillary border of the scapula, causing a comminuted fracture of the head and neck of the humerus. A large fragment of necrosed bone was removed on 21st August. The fracture united with comparatively free movement of the shoulder joint. He was discharged and sent on six months' sick leave on 12th October.

3. Sepoy M. S., 45th Sikhs, age 20. Service two years. Wounded at Malakand on 27th July, and admitted to the Base Hospital, Nowshera, on 18th August. The bullet after passing through his water-bottle, entered his right

the bullet entered the iliac vessels and 2 inches in front of the umbilicus, passing through the abdominal cavity. There were no abdominal symptoms. An exploratory incision was made, but the bullet could not be found. The man never complained of pain which would give any indication as to the site where the bullet had lodged. There was much hectic fever with profuse suppuration, and he died on 28th September. Unfortunately, owing to caste prejudices, no post mortem examination could be made.

4. Sower S. S., 11th Bengal Lancers. Service, nine years. Wounded on 17th July, between Chakdara and Kaur, and admitted to the Base Hospital at Nowshera, on 23rd August. He was wounded while in the saddle. The bullet, after drilling a round hole in the butt of his carbine entered at a point midway between the great trochanter and tuber ischii, on the right side, and passed out 2 inches from the centre of the middle line of the perineum. He made a good recovery, and was discharged on 2nd September, and sent on two months' sick leave.

The above four cases are of considerable interest for the following reasons:—

1. In that it shows, first, how necessary it is to place the man in the position in which he was when struck to get a good idea of the course of the bullet; and secondly it shows how a bullet sometimes travels in the closest proximity to important bones, vessels and nerves without causing any lesion of these structures.

No. 2 is a good example of the excellent results that can be got from antiseptic surgery at the front.

No. 3 is also interesting in that there were no abdominal symptoms; this was accounted for by the fact that the bullet probably lodged in the iliacus muscle or thereabouts, and never really penetrated the abdominal cavity.

In No. 4, when the Sower was hit, he was galloping to the relief of Chakdara, and had it not been for the bullet passing through the stock of his carbine, which must have decreased its velocity very considerably, he would probably have been severely injured, as the bullet would have passed into his left thigh also; as it was it passed between his right thigh and the saddle.

—O—O—

THREE CASES OF ACUTE INTESTINAL OBSTRUCTION.

By WM. HUNTER, M.A., M.D., B.Sc.
Nussersabad.

CASE I.—CHHOTU, age 35, strongly built muscular man, was suddenly taken ill on a Wednesday afternoon at 4 o'clock.

His first idea of anything being wrong came to him in the form of a sudden seizure of pain. This was confined to one spot in the neighbourhood of the ilio-caecal valve. The pain was agonizing, and any pressure of the hand over the spot served to intensify it.

He did not think it anything more than colic, and in the evening sent for my native assistant. Colic was diagnosed and a purgative (castor oil) administered. In a short time this was vomited and some tea, which he drank, was also returned. Early on Thursday morning I was sent for, and the patient, who had had some time to study

the increase in his symptoms, gave a good account of his case. The pain was very intense, and on palpation there was a sausage-like tumour along half the length of the ascending colon; this was known to the patient, who called it a girth. There had been two or three attacks of vomiting, but finding that everything taken only aggravated the vomiting, the patient had refrained from further attempts at swallowing.

He had passed no urine since the attack of pain, and no motion or flatus had passed by the bowel.

The patient too was aware that tympanites was present and the tongue was dry and furred.

There was no doubt of the case being one of acute obstruction.

I gave him a full dose of chlorodyne, commanded absolute rest, and had two stones placed under the two lower limbs of the charpoy on which he lay.

The presumption was invagination. All food was forbidden, save a little cold beef tea and some dāl pāns, and drinks of water were to be partaken of sparingly. Considering that the rains had not burst, the above conditions seem hard as thirst (great) was one of his symptoms.

In the evening he was a little better, and on the following morning was distinctly easier. He had taken, in addition to the chlorodyne, three 1 grain pills of opium. These were given in accordance with the increase or decrease of the pain. When the pain was markedly lessened, the treatment was purely expectant, watching the course of Nature.

For three days the patient remained quietly in bed, there was no further aggravation of the symptoms, and relief came on the fourth day in the manner in which these cases generally recover. Care in his diet was enjoined and no relapse took place.

CASE II.—This patient was also a well developed man, of known temperate habits. He was well known to me and was subject to bilious attacks often followed by slight jaundice.

In the rains he came to hospital to show me a round prominent swelling on the right side under the ribs, in shape globular and to pressure resilient. There was little difficulty in diagnosing the tumour as the gall-bladder, and ordering the patient olive oil, I kept him under observation. The tumour was about the size of an orange and was smooth to the feel and moveable slightly from side to side. There was no pain complained of. The diagnosis was obstruction of the cystic duct in all likelihood by a gall stone. Several mornings later I was hurriedly summoned to find my patient in a collapsed state, his friends standing round expecting him to expire.

He had risen up to go to stool in the morning and walking along he suddenly experienced an excruciating pain, as if something had broken inside and he had rapidly become collapsed.

Mental query while gazing at the man—What has happened? The globular tumour had disappeared, but already some tympanites was showing itself. The presumptive diagnosis was rupture of the tumour into the peritoneum.

The patient survived the peritonitis which followed,

but these were rapidly developed abdominal aches, which so alarmed the patient that he pressed us to stop.

After this collapse there was three days of intestinal obstruction during which I was entreated for purgatives, but I need hardly say this request was refused.

Under treatment the aches also disappeared, and eight months later, the patient is strong and well with no sign of the tumour and with no jaundice.

Where is the gall-stone which obstructed the duct? No trace was found in the stools.

How much was the duct ruptured? There is no area of dense inflammatory formation which is the common sequel.

The patient for several months complained of pain in the neighbourhood of the sigmoid flexure. Is the stone buried in an adhesion there?

The patient has thus escaped collapse from rupture, peritonitis, intestinal obstruction, and ascites, and at present is as well, if not better, than he was before this critical attack.

He belongs to the sweeper caste, which is supposed to be one in which there is little temperance in food or drink. The man I knew to be of temperate and active habits and doubtless this helped to tide over the crisis.

Apart from the opium used during the intestinal obstruction period, ammon. chlorid., taraxaci, and potass. iodid. were the chief medicines employed.

There is an additional point in the case to be noted; namely, the appearance of the tumour *without pain*.

When there is this rapid and painless dilatation, the explanation is well expressed by RUTHERFORD MORRISON. "Like the urinary bladder, the gall bladder will become contracted and hypertrophied when dealing with a partial obstruction, and like it will dilate painlessly when all its efforts to overcome the obstruction are futile."

When my patient presented himself I advised early operation, but *because of the absence of pain*, the patient wished to wait a few days to see if relief would of itself occur and so obviate the need for operation.

CASE III.—Intestinal obstruction of 12 days duration.

This was a woman, a widow about 30 years of age. She would give no history.

There was obstruction with tympanites, but with little abdominal tension.

Later on a history of abortion was given, but as the woman herself had been a party to bringing it about, no correct account was possible. The temperature rose to 101° and occasional vomiting occurred in the course of the disease. Serious symptoms were easily controlled by opium, and after the 12th day primary and secondary relief of the bowels took place.

Remarks.—I have included these three cases under the term "Intestinal Obstruction" for the very simple reason that this to the patients concerned was the most serious element in their case, and that for which they prayed for active treatment.

As I have written in the *Record* on this subject before, I prefer to quote the words of Professor WHITLA on the question of the use of opium in this affection. Compared to what I have read elsewhere, it shows a much better appreciation of the value of the judicious use of this drug in obstruction.

"Opium is of the greatest service, and is to be given in proportion to the amount of pain present. There is, however, one serious objection to it, but which nevertheless cannot be permitted to forbid its use—i.e., it tends to mask the symptoms and may mislead. The experienced physician will constantly have to make allowance for this, and have it ever before his mind in weighing the serious issues as the case advances. The opium should be given as the case may indicate. Thus, in violent sudden pain, soon followed by vomiting, the hypodermic injection of $\frac{1}{2}$ grain of morphia, or an enema containing 45 grains of laudanum should be given. As a rule, solid opium, or the powdered preparation made into pills, should not be administered owing to the retardation of absorption."

—O—

SPINAL PARALYSIS DUE TO DEEP SEA DIVING.

By ASSISTANT SURGEON G. R. GAUDOUX, M.D.,

Civil Surgeon, Mergui.

I don't think it is generally known that deep diving often produces spinal paralysis. In the Mergui Archipelago, pearl fishing is carried on and is attended with this danger in greater depths than 20 fathoms. Of course this diving is carried on with the aid of diving apparatus. My first patient was a Manila diver. He stated that a few minutes after coming to the surface he lost partial use of his lower extremities. A few days later, on admission into hospital, I noticed he was able to draw up the lower limbs, although with some effort; sensation was not impaired; he had a large open bed-sore, and his left buttock was hard, swollen and exquisitely painful. He also suffered from retention of urine and loss of control over the rectum. The water was daily drawn off and the bowels relieved by warm water enemata till control was re-established. About 8 oz. of thin offensive smelling pus was drawn off the gluteal abscess by means of a trocar and cannula and the discharge continued for about ten days later. After this I got him to walk, his gait was peculiar, his feet were thrown forward and brought down with a thump, there was no loss of co-ordination, and he could not walk without the aid of a stick. I passed a phial of hot water down his spine and he cried out with pain when the point of irritation was reached. The irritation was from the symptoms, due to hæmorrhage within the cord. The second case was a Japanese. He sought admission sometime after he was paralysed. In him there was impaired sensation. He could not correctly locate pain, that is a pin prick on the dorsum of his foot would be located in the plantar surface, while a light prick would not be felt at all. His gait was spastic, and he swayed if he attempted to walk with closed eyes. He also required the aid of a stick. I was able to locate the point of injury in him also by passing down the spine a phial of hot water. He informed me that early in the attack he daily drew off his urine, and his friends opened the gluteal abscess with a pocket knife; the scar of the opening was present. In a third and slight case there was pain along the costal nerves; and difficulty in taking a deep breath. From these symptoms the paralysis were evidently due to hæmorrhage within the cord and the variations in the symp-

toes due to the extent and locality of the bleeding. A passer of some experience informed me that he had seen divers come up apparently well, become paralysed a few minutes later, the paralysis increase and the man die within a few hours. He also said the administration of stimulants invariably made the sufferer worse. He attributed the cause to diving beyond a certain depth, to remaining too long under water, and to coming up too rapidly, and these were points that experienced divers avoided. Paralytic divers returned to their work before being completely cured, and it is strange they are able to walk better at the bottom of the sea than on land. The treatment adopted was the administration of ergot in the early stages; later strychnine, massage and electricity.

FEARFUL MUTILATION OF LOWER LEG.

AMPUTATION: RECOVERY.

By JOHN V. JAMES, D.G.M.C.

Assistant Civil Surgeon, Mussoorie.

A PAHARI lad, age about 10 years, was brought to hospital by his grandfather from a village about 3 days' march from Tehri, which is itself 7 days' march from Mussoorie. The old man stated that about a year ago, the boy fell from a tree and broke his leg, and when picked up was found with one bone sticking out through a wound. Some bandages or rather pieces of dirty cloth were applied and the boy was carried home. Nothing further was done. The hill village from which the boy comes has snow on the ground throughout the greater part of the year and accounts for the partial preservation of the limb from decay and gangrene.

On examination the broken tibia was seen protruding through a foul wound, the bone was dry and crumbling and serrated. The foot was swollen to an awful size being 7 inches across the middle and in appearance reminded one of the head of a cobra, the toes appearing like the mouth and two wounds like the eyes.

The leg from the knee to the ankle was curved and shortened to 15 inches, while the sound leg was 19 inches. The crumbling bone was dry but had no offensive smell, but the three wounds were very foul smelling. The skin was cedematous, as far as the knee-joint, which itself was much swollen.

The boy had lost flesh to a very great extent and was very anæmic. The temperature was normal.

The boy was admitted as an in-patient, and prepared for an operation.

The next day (26th March 1898) the patient being put under chloroform by Mr. HUXAM SINGH, my Hospital Assistant, I examined the limb and decided to amputate the leg above the knee, as no good flaps could be had below it. The bone was sawed through about 3 inches above the knee, the anterior flap being 1½ inches and the posterior 3½ inches.

The main arteries were ligatured and an Eschmarch bandage was removed; the stump was then washed with carbolic first and perchloride after; silver wire sutures were applied and a drainage tube inserted. Mercuric guaze was applied in pads and covered with similar lint. Boric wool finished the antiseptic coverings and a long bandage fixed the dressing. The boy felt slightly sick on recovering from the anaesthesia, but soon got over it.

There was not much rise of temperature, the stump was dressed again after the 5th day, when the tube (drainage) was removed.

There was no rise of temperature for another 3 days, and the leg was redressed on the 8th day, when the flaps were found well united.

The patient is still in hospital and is doing very well.

It is strange how these ignorant hill men do neglect themselves and their children.

It is a wonder that gangrene or anything else did not occur.

It would be cruel to prosecute the grandfather as the patient being an orphan would suffer thereby.

NOTES ON A CASE OF OLEANDER POISONING.

By ASSISTANT SURGEON H. D. PANT, I.M.B.,

Coonda.

THE roots, leaves and bark of nerium odorum, locally called "kaner," belonging to the order apocynoid are intensely poisonous. A case of some interest was brought to me yesterday morning. A Mussulman coachman was advised by some quack to take a sherbet of the leaves of kaner as a diuretic for gonorrhoea from which he had been suffering. Early in the morning he pounded seven leaves of oleander mixed with water and sugarcandy and drank off the sherbet. Uncontrollable vomiting set in. Two hours afterwards he was brought to me. The symptoms were violent retching, vomiting of small quantities of greenish fluid, slight pain in stomach. His pulse was extremely slow and feeble, counting only 36 per minute, cold clammy sweats on face and forehead. The stomach was at once washed out and bismuth and morphia given and a mustard plaster over the stomach. Nausea stopped within two hours, but the slowness of pulse continued till the afternoon, when it was 50 per minute. He was discharged cured this morning with pulse rate 70 per minute. As regards pulse, its action was analogous to digitalis. Oleander is not used internally. Could not a mild tincture be prepared and used as a substitute for digitalis in cases where the lowering of heart's action is indicated? The rapidity of action and its sustained character were remarkable in this instance.

THE Indian Medical Record.

1st May 1898.

THE ADMINISTRATION REPORT OF THE COMMISSIONERS OF CALCUTTA FOR 1896-97.

THE LATE HEALTH OFFICER'S WORK.

To us the most interesting part of the Administration Report of the Commissioners of Calcutta for 1896-97 is the Health Officer's Report: and more particularly that part of his report which deals with the subject of plague.

From a perusal of this Report, the conclusion is forced upon us, that if there was one man in India more than another who realised to its full extent the threatening danger, the absolute necessity of keeping the plague at a distance, and the precautions that were necessary for the successful attainment of this object, that man was the late Health Officer of Calcutta, Dr. W. J. SIMPSON.

But let the facts speak for themselves.

On the 24th September 1896, he addressed a letter to the Chairman of the Corporation of Calcutta, stating that plague was reported in Bombay and recommending that steps be at once taken to prevent its importation into Calcutta; he pointed out the intimate nature of the communications between Calcutta and Bombay, recommended the examination of all passengers before leaving Bombay and at different stages of the journey as well as at Howrah; urged that the railway authorities should be asked what special precautions they were taking to prevent the spread of the disease by their passengers, work people and goods, that the attention of the Port authorities should be drawn to the necessity of making special arrangements for the examination of all ships, etc.

He further requested the Corporation to take certain precautionary measures, including the appointment of medical inspectors, the formation of isolation hospitals, securing of ambulances, the declaring of plague to be a dangerous infectious disease under Section 321 of the Municipal Act, the granting of power to the Health Officer to isolate suspicious cases, the appointing of a European superintendent to supervise the cleansing of the city, the appointment of a Health Officer for Howrah, etc.

Now on this very date, on which we see Dr. SIMPSON putting the Calcutta Corporation on its guard at every point, what was the state of affairs in Bombay.

On the 24th September 1896, the Health Officer of Bombay, in reply to a question as to whether bubonic plague was in Bombay, wired as follows:—"*There has been suspicious form of fever with enlarged glands in one locality, and one class for about three weeks; the mortality is small, it looks suspicious, but by no means certain.*"

It is easy enough to be wise after the event, and we now know only too well the appalling results which may be traced, more or less directly, to the extreme unwillingness of the Bombay authorities to admit that plague had made its way into their city, for three weeks these suspicious cases had been occurring, for three weeks a frightful epidemic was quietly incubating in their midst,

but as yet they were not aware of the nature of the disease. The awakening was a rude one, and for their initial disavowal they have had a heavy penalty to pay.

The next day, 25th September Dr. SIMPSON despatched Dr. Durr to Bombay to inquire into this suspicious disease the true nature of which was already clear to him.

At this time there was absolutely nothing to prevent one of these cases arriving in Calcutta at any time, and should one arrive, there was equally no place in which to isolate it.

Dr. SIMPSON saw this and wrote two letters with the object of obtaining the necessary accommodation. One was to the superintendent of the Campbell Hospital, Sealdah, but as nothing in this country can be done without the sanction of the Government, the other was to the Secretary, Government of Bengal, Medical Department, Darjeeling, enquiring "whether in the event of suspicious cases of fever with glandular enlargement or distinct cases of bubonic plague occurring in Calcutta, such cases might be admitted to the isolation wards of the Campbell Hospital."

And now we come to an interesting episode which may open the eyes of some to the advantages of Government from the snowy Himalayas.

The date of the reply, a letter, is four days later, 30th September, it presumably did not reach Calcutta till six days later or the 2nd October, during any of which days the cases referred to might have been introduced into the city.

The reply to the above inquiry is as follows, quite a little miniature of red tape:—"I am to say, with reference to a query irregularly addressed by the Health Officer to Government direct, that the Campbell Hospital cannot be used for the purposes of a plague hospital." The divinity which hedges a Government must not be set aside, no matter what the urgency, by such a person as a Health Officer. Plague is quite a secondary affair, but the sanctity of the correct channel for official correspondence must be kept inviolate.

In this letter it is mentioned that a "telegram of to-day's date from His Excellency the Governor (of Bombay) shows that the character of the disease is still open to question."

The last paragraph runs:—"It is premature at present to propose any interference with, or medical examination of, railway passengers."

During this time, according to Dr. Durr's reports from Bombay, there were on 29th September 18 cases and 13 deaths, on the 30th September 26 cases and 24 deaths and on 1st October 21 cases and 15 deaths; all from the mysterious disease which the Bombay authorities were so loath to admit was plague.

We cannot discover the exact date upon which they admitted, if indeed they ever did admit officially, that there was plague in Bombay. On the 1st October, the Bombay Governor wired:—"If disease is plague, then of mild modified type, and no tendency to increase at present."

On the 2nd October he wired:—"Situation in Bombay no worse. Municipal Commissioners state if disease increases, necessary measures will follow."

What a terrible lesson does this last sentence convey to-day? When they undoubtedly died following they still are! But they were outstanced, the quarry had got away, and we now see the line of chase marked with over 80,000 corpses.

That the "following" policy was not the one adopted by Dr. Simpson is clear from the Report before us. On the 25th of September he announced, "plague appears to have broken out in Bombay," and published a brief description of the symptoms as well as directions to house holders for the prevention of plague.

In his letters, dated 3rd October, he advised the Chairman of the Calcutta Corporation as to the "Special Powers required under Section 334, Municipal Act," and further wrote this memorable sentence:—"I may, moreover, mention that epidemiologists are quite prepared to see a recrudescence of the plague such as has not been in this century."

In a letter, dated 4th October, he presents the Chairman with a complete scheme for a plague hospital.

It was not, however, until the 8th October that the Commissioners of Calcutta notified "bubonic plague, or any form of typhus fever with glandular swellings to be a dangerous disease under Section 321 of the Calcutta Municipal Act." This action was thus only taken after the lapse of 13 days from the date of Dr. Simpson's first letter.

We consider Dr. SIMPSON's proceedings throughout this trying time to be an admirable and complete lesson to all Health Officers under similar circumstances.

It is pretty certain that the exact amount of risk which Calcutta ran of plague importation in those days will never be known; it is even an open question if cases of plague did not actually occur within municipal limits, both in human beings and in rats.

In the Report before us, there is the detailed account of a case which occurred at Howrah, in an individual who had recently arrived from Bombay.

There is also an interesting and highly suggestive account of an outbreak of glandular sickness with great mortality among rats, in two houses in the Marwari quarter, in one of those houses a child also was ill with fever and glandular swellings, and it is a remarkable thing that diplo-bacteria assembling the specific organisms of plague were found both in the child and in the rats. By energetic measures this epidemic amongst the rats was stamped out.

With reference to the Howrah case, after careful examination Dr. SIMPSON, Dr. TOMES, and Dr. COBB, all agreed that it was a case of plague (*Pestis Asiatica*), "The Medical Board, investigating the case later on, came to the conclusion that there was no evidence to consider this a case of true bubonic plague.

In this state of uncertainty the case must remain; it was carefully investigated by men of undoubted ability, and they were unable to agree as to the diagnosis. We are unable to throw any further light upon it, but we cannot forget that there was a similar doubt about the first cases in Bombay, and that they were described as being of a mild and modified type.

Whatever the true nature of this case may have been, of one thing at least there cannot be the least room for doubt, that the attitude of Dr. SIMPSON, and those who

agreed with him, was the right one; far better, at such a time, to diagnose fifty doubtful cases as plague, than let one pass on the plea that the diagnosis was not positively certain. It was Dr. SIMPSON's duty to protect Calcutta, and his action was the only one possible for him under the circumstances.

At this time the Government of Bengal was oppressed by two great fears: the fear of plague, and the fear of panic, and it is not altogether clear that it did not permit the latter to exercise a preponderating influence in its councils.

The action of the Bombay Government in delaying to acknowledge that the city was infected by plague may have been dictated by somewhat similar motives, we all know now what it has led to.

Calcutta may well congratulate itself that it had a Health Officer who was equal to the emergency, to whom the methods of concealment and delay, of doubting and waiting were not acceptable, and to whose energetic measures may in a large measure be attributed the safety of the city.

—:—

TYPHOID FEVER AND INFECTED WATER SUPPLIES: THE MAIDSTONE EPIDEMIC.

To trace an outbreak of any infectious disease to its starting point, and demonstrate with certainty its exact cause is a task beset with difficulties, and it must be confessed that the results of investigations of this kind are far from satisfactory.

The ease and certainty with which any single expert will unravel all the intricacies of a difficult case, are only equalled by the bewildering differences of opinion that arise when two or more experts are assembled for the same purpose.

On many very important points sanitation is still in the empirical stage, and divergent views prevail about what appear to be very simple matters, the worst of it is that as our means and methods of research become more perfect, these difficulties and differences seem to increase, this is of course only the natural result of the widening of the field of inquiry.

As a good example of the futility of building up clumsy theories, and of the facility with which they can be constructed to suit any possible combination of circumstances, we would refer the reader to an article called "Mixed Factors in Infection" which appeared in the *British Medical Journal* of 12th March; this stout supporter of the waterborne theory of every disease, finds itself in difficulties and is obliged to "hedge" and very mixed and amusing is the result.

The comfortable arm-chair doctrine that typhoid fever is essentially a waterborne disease has been for many years accepted with almost blind acquiescence, and it has become a regular routine on the occurrence of a case, to send the water to be analysed, true the results were usually nil, but of course that proved nothing, and in India at least the source of the large majority of cases has never been traced.

Of late there has been a healthy tendency to take a wider view of the matter, and it is becoming more evident day by day that where typhoid fever is concerned, many things besides water and milk have to be considered.

Regarding the recent epidemic at Maidstone (Kent), as read in the Annual Report of the Sanitary Commissioner with the Government of India for 1906, page 28: "Just as when tubercle bacilli gaining access to a blood vessel are carried to all parts supplied with blood, and produce general tuberculosis, so was the enteric bacillus distributed by the water pipes at Maidstone."

Leaving out of sight the very questionable proceeding, unfortunately only too much favoured by many writers of the present day who call themselves scientific, of arguing from one bacillus of which we know little to another of which we know less, the above summary of the Maidstone epidemic is altogether without support from direct evidence of any kind, it is therefore to be regretted that it should have appeared in such an important Government Report.

Judging from recent developments, the late Maidstone typhoid fever epidemic is likely to provide food for controversy for some time to come.

The *Public Health Engineer* deserves the thanks of all for its energy in taking this matter up and in specially retaining Professor WANKLYN, M.R.C.S., to investigate the causes of the Maidstone epidemic, and by so doing it has thrown a bomb into the camp of those who have expressed themselves in favour of the water-borne origin.

Professor WANKLYN, whose report appeared in the *Public Health Engineer* for 5th March, and whose position we need scarcely remark, is second to none as a water analyst, gives it as his opinion, without the slightest hesitation, that the water had nothing whatever to do with the causation of this epidemic. The fact that the typhoid bacillus was never found in the water is admitted on all sides, and regarding the failure to find it Professor WANKLYN remarks: "This utter failure is rendered especially emphatic by the extraordinary opportunities and facilities for that description of investigation which were afforded by the Maidstone Water Company. On the 5th of September, the sanitary authority first became aware that an outbreak of typhoid fever was imminent, and on that day Dr. WASHBURN was communicated with, and from that time onwards during the whole course of the epidemic, the works of the Water Company have been at the disposal of the sanitary authority for any kind of investigation which that authority might choose to undertake."

"Under these circumstances, the only construction which this cardinal fact will bear is, that the Maidstone water has in reality been devoid of typhoid bacilli throughout the epidemic."

This is of course the obvious conclusion, indeed it is difficult to see how any other conclusion can be drawn; but from the statements made on the subject, one of which we have given above, it would appear that the very fact of the typhoid bacillus not being found is to be accepted as proof that it was present.

On what evidence then is the water-supply accused of having caused the epidemic, according to Dr. WASHBURN "the Tatham-in-Field spring was undoubtedly contaminated with animal excreta on both occasions on which it was examined; it contained an excess of bacteria and many coil bacilli."

On the other hand, Professor WANKLYN says:—"Dr. WASHBURN's further statement that the Tatham-in-

Field spring was undoubtedly contaminated with animal excreta is totally at variance with numerous facts in its direct opposition to the observations of Dr. ERIC BOCKMANN, and is contradicted by the chemical analysis of Mr. GARGOY and Dr. ADAMS. The striking absence of any considerable proportion of free ammonia shows conclusively that there was no sewage pollution."

Thus do the experts differ about simple matters. Professor WANKLYN is inclined to attribute the outbreak to the excessive rains of the latter half of August and the beginning of September, waking up to sinister activity the 4,000 elongated cesspools charged with food, fostering filth, continually producing air-polluting and disease-prevailing vapours. The elongated cesspools referred to are of course the town's sewers, and if we had forgotten the fact, that, at the discussion on the "Prevention of enteric fever" held in January last, at the Royal Medical and Chirurgical Society, both Professor COCHRAN and Dr. PATER expressed their belief in sewer gas as a cause of enteric, we should be now reminded that this old theory is by no means dead.

With reference to the alleged pollution of the Tatham-in-Field spring, it is a curious thing that the cottagers who lived in its immediate vicinity and who drank this supposed polluted water at its source entirely escaped infection.

That the sewers were in some way closely connected with this outbreak is the conclusion arrived at by the *Public Health Engineer's* Special Commissioner who stated in that journal in October last that "the people who live in the London Road and drain into the main sewer, have nearly all had the epidemic in their houses, while those who have drained into water-tight cesspits have, in the majority of cases, escaped."

The result of a series of interesting experiments upon the effects of sewer gas in animals was to show that it lowered the vitality and rendered animals exposed to its influence more prone to contract infectious diseases, from the above it would appear that the conditions that prevailed at Maidstone simply amounted to a collateral series of experiments on human beings, the results of which were sufficiently similar.

However that may have been, the end to which all these investigations were directed has not been reached, and the most important question of all, where the bacillus actually came from, is wrapped in as great obscurity as ever; this result we say is unsatisfactory, the more so as the Maidstone outbreak was more extensively and carefully investigated than any of other epidemics with which we are acquainted.

The result, no doubt, will be that in all future outbreaks of a similar kind, the inquiries will be of a more rigorous description than heretofore, and that in such investigations the water companies, or the authorities who are responsible for the purity of the water supply, will take their part and by all means in their power endeavour to prove that their supplies were uncontaminated.

As showing how a polluted water supply may exist coincidentally with a high typhoid fever mortality and yet be unconnected with it, Dr. COCHRAN's paper on the "Etiology of typhoid fever in Munich" (*Lancet* Feb. 5) which

inflammation of the lymph glands in the groin of 18th March, is a sufficient confirmation.

The author of this communication, Dr. CHILDS has been justly quoted by the *Manchester Medicinal Review*, and in the opening sentence our German friends seem to be poking mild fun at their English colleagues when they say "People in England are so accustomed to search for the cause of typhoid fever only in water and milk, that Dr. CHILDS's paper, read before the Epidemiological Society of London, created considerable surprise."

CLIMATIC BUBOS.

INFLAMMATORY swelling of the lymph glands, without any apparent cause, is a sufficiently common complaint in Calcutta.

Various views as to the origin and cause of these bubos have appeared in the medical journals, so that the following translation of a paper on "Climatic Bubos," by Dr. O. NAGEL, which appeared in the *Monatsschrift Weidmannschrift* for 9th March 1898, cannot fail to be of interest to many :—

"The question is not yet decided if in tropical countries there is such a thing as a climatic inflammation of the inguinal glands, that is, an inflammation which, after the exclusion of all other etiological causes, must be attributed to the effects of climatic influence alone.

"While the answer to this question, be it in the affirmative or negative, is not of very great importance from the therapeutical stand-point, it possesses a certain etiological interest ; it cannot therefore be amiss to communicate the observations that have been made on this subject, which, in the literature of tropical diseases, has received but scant notice.

"This question has been amply dealt with by RUGER who, on the strength of a considerable amount of material (38 cases), adduces proof of the existence of climatic bubos.

"RUGER's observations were made on the East Coast of Africa, and two off Zanzibar during the blockade of the coast by the German squadron.

"The fact that all his cases occurred on boardship, does not affect the correctness of his observations, because, as he says, the ship was as often close into the land as at sea, and the men were subject to exactly the same climatic influences as if they had been on shore.

"During the year 1891-1892, I had an opportunity of making observations on this subject in different parts of German East Africa, not only on the coast but also in the interior, at first I received with distrust the oft-repeated assertions of Europeans living in the country that they were suffering from climatic bubos ; the relatively large number of cases of inflammation of the inguinal glands which came under my treatment, induced me, however, to pay special attention to the subject.

"The result of my observations led me to conclude that climate was very probably, if not certainly, the cause of the affection.

"It may be that the influence of the climate consists in some unknown cause of disease or inflammation which gains an entrance into the body and then gives rise to

these changes ; but as to the mode or manner of the invasion nothing can be said at present.

"The designation of 'climatic bubo' is, of course, but only provisional, until a term expressing the exact nature of the inflammation can be found.

"It is, of course, necessary to exclude, in the cases under consideration, all those affections which under ordinary circumstances give rise to inflammation of the inguinal glands ; the different forms of venereal diseases, especially gonorrhoea and soft chancre, also wounds of the lower extremities and other forms of diseases, particularly tuberculosis, in which this condition may occur.

"Venereal diseases were not easily excluded, but certainly in my cases there was no recent infection, nor was there any sign of previous infection, nor did any affection of the genital organs come under my observation.

"There remains then the possibility of a causal connection with malaria.

"It is well known that malarial fever of all kinds from the lightest to the most severe, prevails on the East Coast of Africa, pernicious cases and the various complications have been described with sufficient frequency.

"There is no difficulty in imagining that a disease which prevails in so many forms, and affects so many different organs, might also localise itself in the lymph glands, and it must be borne in mind that the inflammation of the inguinal glands in question is often found in an individual who is at the same time suffering from malarial fever.

"We can therefore clearly understand an observer tracing an internal connection between the two diseases as MARTIN did. MARTIN draws attention to a particular form of inflammation of the lymph glands—(moreover he only mentions an inflammatory swelling of the external iliac and orural glands, the inguinal were not affected)—as subject to malarial influence and which subsides quickly under quinine.

"On the other hand, RUGER, after carefully excluding all other exciting causes, as venereal infection, agrees with me in rejecting malaria as the cause of the inflammation of the lymph glands.

"The reasons given by him are, that the fever which accompanies the glandular inflammation resists quinine, but disappears when the affected glands are removed ; and that inflammation of the inguinal glands complicated none of the cases of malarial fever observed by him.

"In my cases, the same reasons led me to the conclusion that the inflammation of the inguinal glands was due exclusively to the climate, which, as above mentioned, gave rise to some unknown agent which produced the inflammation, although in two of my cases malarial fever was present at the same time.

"The details of the cases, their number is roughly one-third of those given by RUGER, resemble in all particulars those mentioned by him as his milder cases, in none did the fever exceed 102.2 F., and in only two did suppuration occur, necessitating incision of the glands ; the swelling generally developed quickly with rather more than less pain. In one of the cases severe pain on pressure in the bend of the groin persisted for almost a week before any swelling could be detected.

"The treatment was the ordinary one, of rest in bed, abstraction with mercurial ointment, fomentations, and

pressure by means of a bandage; with the exception of the two cases in which pus formed, this led to speedy resolution.

"Quinine was given in all cases, but had not the smallest effect upon the process.

"The fever and other unpleasant symptoms usually present disappeared with the local affection.

"If the inflammation of the lymph glands was a localised form of malaria, it presumably would to a certain extent follow the course of the malarial fever in those cases where the two were associated; it would certainly be influenced by quinine, as this is undoubtedly the case in all the usual symptoms which accompany the manifestations of malaria.

"But even as a complication of malaria, in the sense in which a complication is understood by SCHELLONY, the inflammation of the inguinal glands cannot be accepted.

"SCHELLONY defines malarial complications as distinct affections, which are accustomed to appear so often in the wake of malaria that a distinct etiological connection must be assumed, without our being able to state distinctly to what cause the connection is due.

"Amongst such complications he includes malarial pneumonia and dysentery. MARTIN also considers dysentery to be a complication of malaria, on account of the frequency with which they occur together.

"With STRENDL, I hold that in such cases the connection is purely accidental, and that the diseases referred to must be considered separately, and this also is the case with the inflammation of the inguinal glands.

"Even if no direct proof can be given for either of these views (whether a malarial complication or arising from purely climatic causes), yet in favor of the latter is to be urged the perfectly independent course of the disease, which is influenced neither by the malarial fever nor by quinine.

"The fact that inflammation of the inguinal glands is sometimes coincident with malarial fever is easily explained, in that the tropical climate produces the climatic bubo through certain different influences, in a body, already attacked and weakened by malarial fever.

"On the other hand, it is clear that the climatic disease of the lymph glands can be primary, and so facilitate the entrance of the malarial organisms into the body.

"I have still to mention that in the total number of cases of malarial fever (about 300) which during the years 1891—1892 were under my treatment, with the exception of the cases above mentioned, I met with no cases in which inflammation of the inguinal glands occurred at the same time as malarial fever.

"I regret that I cannot adduce any observations on the blood, a method which gives more accurate results, to show whether malaria is the exciting cause of inflammation of the lymph glands or not. So that the result of this communication can only be to establish the probability of the existence of climatic bubos.

"Considering the small number of communications on the subject, every contribution must be welcomed, until the matter is set at rest by means of exact observations."

THE LIFE AND TIMES OF THOMAS WAKLEY, FOUNDER OF THE LANCET.

In considering WAKLEY's Parliamentary career, it will not be necessary in these pages to do more than briefly notice the various matters of interest to the medical profession with which his name is connected.

An important result of WAKLEY's long and unceasing exposure of the anomalies of medical education, of the "dull, feeble exclusiveness of the Royal College of Physicians of London," the "tyranny and ineptitude of the Royal College of Surgeons," the "pettifogging malice of the Society of Apothecaries," was the appointment on the 11th February 1834 of a Parliamentary Committee of Inquiry (called Warburton's Committee) to take evidence on a large number of diverse subjects, connected with almost every aspect of the profession of medicine.

The proceedings of this Committee did much to enlighten the "House" and the public on medical matters, but led to no immediate legislation.

On the 8th March 1836, WAKLEY introduced the "Medical Witnesses Bill;" it provided for the payment of all medical witnesses at coroner's inquests, of one guinea for their evidence, and one guinea for post mortem examinations. This Bill became law in about three months, and met with no opposition.

In 1840, when Sir JAMES GRAHAM's Vaccination Bill came on, WAKLEY introduced two important amendments, in the first, he vindicated the right of ordinary practitioners to become vaccinators under the Act, Poor-law medical officers only being recognised as the Bill stood.

In the second it was made a penal offence to inoculate with small-pox, or to expose persons intentionally to infection.

About this time he supported a measure to prevent the burying of the dead in the over-crowded churchyards of the cities, protesting against a system by which the dead poisoned the living.

He also spoke on the subject of infanticide and illegitimacy, which were noticed to be considerably on the increase.

In 1841 WAKLEY was re-elected for Finsbury for the third time; he was now one of the best known men in London. It was in this year that *Punch* was started, and it must be looked upon as a tribute to WAKLEY's importance that the great London Comic Journal satirised him in its opening number.

For an aggressive man, which he undoubtedly was, WAKLEY's demeanour in the "House" was singularly ingratiating; he always kept his temper in perfect control, and in the only fracas with which he was associated in Parliament he was the justly offended party.

Mr. EDMOND WOODHOUSE, a Norfolk member, in the heat of debate, once again resuscitated the old scandal of Argyll Street, the burning of WAKLEY's house. WAKLEY at once called the attention of the House to the matter and received a full apology.

This incident furnished Sir ROBERT PEEL with an opportunity for the performance of a very graceful act. He addressed a long and eloquent letter to the eldest of

WAKLEY's—see, then twenty-three years of age, testifying to the complete esteem in which his father was held by the whole House; this, coming from the most powerful and prominent statesman in the kingdom, formed a remarkable testimonial to WAKLEY's public merits.

In 1846 WAKLEY obtained leave to bring in a Bill for the Registration of Qualified Medical Practitioners and for amending the Law relating to the Practice of Medicine in Great Britain and Ireland. This was his greatest Parliamentary work; it never became law, but it led directly to the very important Medical Act of 1858.

A select committee, on which WAKLEY had a seat was appointed to inquire into medical matters generally and he enjoyed the pleasure, not often accorded to agitators, of cross-examining his old enemies, the Presidents of the London Corporations. This was a complete triumph for WAKLEY.

Twenty-one years previously he had formulated certain complaints against the College of Surgeons, and was expelled from hospitals and reviled, sixteen years before he was violently assaulted in the theatre of the College, now it was his duty to call upon the heads of this body for an account of their stewardship, and to cross-examine them as to the management or mis-management of their affairs.

In 1852 WAKLEY's Parliamentary career came to an end, the terribly laborious life he had led as coroner for Middlesex, as regular attendant at Westminster and as Editor of the *Lancet*, was telling seriously on his health. For fifteen years he had worked relentlessly. He had spoken and written volumes, he had driven literally thousands of miles to hold courts. A serious collapse decided his course of action, and in a brief letter he took farewell of his constituents, thanking them for their loyal support during eighteen years of political life.

WAKLEY's career in Parliament was an unmitigated success. He never attached himself to any party. He was a most adaptable and obliging member in small things, and in large followed a clear and well-defined policy of the Radical sort.

He was interested in, supported, and spoke upon a very large number of subjects of reform, and always with success.

A very outspoken appreciation of WAKLEY in the House of Commons, from the pen of Mr. G. H. FRANCIS, appeared in "*Fraser's Magazine*," and was afterwards published with similar essays in a volume entitled "Orators of the age."

SOME FACTS ABOUT THE ORIGIN OF MALARIA.

BATTEN denies that the poison of malaria enters the system wholly by way of the stomach, and in support of the theory that an entrance may also be effected through the respiratory tract he mentions his experience on the vessel *Valley City* during 1864-65. The ship was cruising along the coast of North Carolina, and although all the water used on board, either for drinking or cooking purposes, was boiled and filtered, yet the number of cases of malaria invariably increased whenever a long stay was made in any river.

COMMENTS AND NEWS.

MEDICAL JOURNALISM.

THE late Mr. ERNEST HART, with whose name the great success of the *British Medical Journal* is closely associated, and which he so ably edited for many years of a busy life, may be accepted as a competent guide on all questions concerning medical journalism.

The following remarks of his, lately reproduced by the *Philadelphia Medical Journal*, will have a special interest, coming as they do so soon after his removal from our midst:—

"The mission of the medical journalist is a great one, it is no longer an accidental function of an otherwise busy man's life. Even the ablest men who have taken that view of journalism have failed to make much mark in that calling. I refer to men of such capacity and standing as JENNER, QUAIN, SPENCER WELLS, BARNES, and JONATHAN HUTCHINSON—all of our later time. It offers a career that repays and requires undivided devotion; one that may fulfil high ambitions and subserve large usefulness. I speak of it as a mission; for no man can reach the ideal of medical journalism who only writes to live; he must live to write."

"The ideal journalist needs to cultivate many qualities which it is not always easy to combine. He should have rapidity of initiative and promptness of decision, for slow deliberation is the grave of opportunity. He needs quick and catholic sympathy; for this is a great source of power; but a corresponding capacity for just indignation is its necessary correlative and qualification. Magnanimity is a necessary editorial quality, for often the best way to remedy injuries is to forget them. Journalism entails much sacrifice. An editor needs, and must have, many enemies; he cannot do without them. Woe be unto the journalist of whom all men say good things. A man, says OLIVER WENDELL HOLMES, whose opinions are never attacked is beneath contempt. For every real thought on every real subject knocks the wind out of somebody."

"An editor must quickly form opinions, and firmly express them, but he does well not to enter into controversy. 'For controversy,' it has been well said by Dr. OLIVER WENDELL HOLMES, 'equalizes fools and wise men in the same way—and the fools know it.' It is a prudent thing to refuse to be drawn into controversy, especially in the pages of one's own journal. Don't lose time in altercation, for in much altercation truth is lost. Let every man have his say, let him contradict you, let him attack, provided he does so in the limits of courtesy and of good temper. Learn from him, and let others learn. Do not answer him or put tags to his letter, unless some rectification of facts is necessary."

An editor is often asked by young writers. "What style would you recommend me to adopt? and what advice can you give me for writing in your journal. It has always seemed to me advisable to recommend the avoidance of style, and to advise those who seek counsel, to avoid straining after style, and to try and say what they have to say as clearly as possible, and to seek mainly the accurate expression of precisely the shade of meaning which it is intended to depict."

On medical ethics he remarked:—"Do unto others as you would have them do unto you, is the golden rule which is enclosed within the basket of general as of medical ethics. But society has found it necessary to formulate a vast number of accepted laws of conduct which are none the less necessary for daily use because they may all be found inscribed in the Ten Commandments."

They specially commendation of principles which every man might wish out if his intellect were always keen, his judgment well balanced, his interest calmly self-judged and easily put aside when they conflict with the general interest. So perfect a being might be content to be a law unto himself; but for others less perfect it has been found in every walk of life that it is well to have at hand, stored in the memory or laid down for reference, decisions and rules already settled by the wisdom, the experience, and the judgment of the wisest and best of our predecessors and our contemporaries—that is, the code of medical ethics, and wise men will not despise it. A strict adherence to the rules of etiquette is sometimes, with shrewd scorn, stigmatised as trades-unionism. We can be well content to leave that phrase as it stands, but let us translate it into its proper language. Medicine is not a trade; it is a profession. And unions such as ours, such as yours, unions which are called the Association of Medical Journalists, or which are called the American Medical Association or the British Medical Association, typify and embody professional union. We accept and convert to our own honor and dignity and to the welfare of the public, the very phrase which is hurled at us as if it were a reproach. Yes, we here are all for medical union. Our duty as medical journalists is to promote professional union."

THE GROWTH OF THE TYPHOID BACILLUS IN THE SOIL

DOCTOR JOHN ROBERTSON, Medical Officer of Health, Sheffield, has published some very suggestive experiments on this subject (*British Medical Journal*, 8th January 1896).

He noticed that the disease had a special tendency to occur in certain areas at varied intervals, these areas he calls "Typhoid Areas," to elucidate the question as to where the actual propagation of the disease-producing organism took place, he collected thirty samples of soil from the most "probable" of these areas.

In none of these samples was he able to find the bacillus typhosus. "Within the past few months," he says, "Professor DELEPINE has been able to demonstrate the presence of *B. typhosus* in the soil of an infected area."

Dr ROBERTSON next proceeded to try if he could grow the typhoid bacillus in the ordinary soil of the district.

The field where the out-door experiments were carried on had not been manured for over ten years, each experimental patch of ground had the turf removed, and nothing was allowed to grow on it.

The method of procedure was to mix a twenty-four hours' old bouillon culture with 1½ gallons of tap water and drunch the ground with it. One patch was inoculated in the surface, one at a depth of nine inches and one at a depth of 18 inches, the soil being carefully replaced.

This was done on the 30th May 1896, on 28th August following, samples were taken and the bacillus typhosus found in all with comparative ease.

On 20th October samples were again taken with similar results, but on 27th November the bacillus could not be found.

Towards the end of August 1896, three more patches were inoculated as before, and these patches received, at intervals of about a fortnight, until 3rd June 1897, doses of various dilute organic solutions, while none of the three patches first inoculated received any organic matter.

On 3rd June samples were taken from each of the six patches. In the first three no typhoid organism could be found, in the last three it was found in every case. The same results were arrived at on 11th July.

Dr ROBERTSON thinks that the results obtained throw some light on the natural history of the bacillus typhosus. "They prove," he says, "that the typhoid organism is capable of growing very rapidly in certain soils, and that apparently under certain conditions the organism can survive from one summer to another."

He draws attention to the fact that the organisms which survived were constantly fed with organic matter, and suggests that a leaking drain might easily fulfil the duty of feeding the bacillus if it were in the neighbouring soil.

The results, however, throw no light upon the difficulty experienced in finding the bacillus in the soil of the "typhoid areas," and as it was found with "comparative ease" in the inoculated soil, we are driven to the conclusion that it was not present in the thirty samples of soil taken from the most "probable" of these areas.

Investigators of the typhoid bacillus lay great stress upon the difficulty of finding and isolating this organism, and constantly remind us that the fact of their not being able to find it, in the face of these difficulties, means nothing. If such be the case, any conclusions drawn from their investigations are worthless; for on their own showing it is open, and even justifiable for anyone to assume that the bacillus was actually present in all the cases where they got negative results.

If on the other hand it can be found with "comparative ease" when it is really present, why do they so particularly emphasise the difficulty of isolating it, and ask us to assume its presence, though not actually demonstrated, whenever it suits their convenience or what they consider to be the probabilities of the case?

SANITARY SCIENCE, THE MEDICAL PROFESSION AND THE PUBLIC.

A VERY able address was given on the above by Dr. HERMANN M BIGGS of New York. He remarked that, "it may perhaps be justly said that no class or profession has contributed as much as the medical profession to the advance of civilisation, to the prosperity of nations, and to the preservation and prolongation of human life."

Sanitary science aims to prevent disease. Formerly four-fifths of all deaths were due to preventible causes, in large cities one-third are still due to them.

DISRAELI once said in the House of Commons "The public health is the foundation on which reposes the happiness of the people, and the power of a country. The care of the public health is the first duty of a statesman."

The high standard of public health has, without doubt, largely contributed to place the British nation foremost in civilisation.

After alluding to the deadening influence on business and the enormous loss attending an infectious epidemic in any large city, Dr. BIGGS said, with the numerous close and rapid lines of communication which now exist between all parts of the civilised world, the rapidity of extension of one of the medieval epidemics would be frightful to contemplate, should sanitary conditions and lack of sanitary knowledge render such an epidemic possible.

All the formidable array of preventible diseases have been confined by the energies of the sanitary authorities within much narrower boundaries. The great plague of modern civilisation,—tuberculosis,—shows a steady and continuous decline in its death-rate, small-pox in former times with all its terrors before the discovery of vaccination, was scarcely more to be dreaded than tuberculosis is now, its death-rate was relatively smaller than that of tuberculosis to-day.

In the seventeenth and eighteenth centuries the average

small death-rate was observed throughout the outbreak, which probably varied from 50 to 60 in London. At the present time it is only about 17.

More than 45,000 people died in Paris during one epidemic of small-pox in the last century, and a third of the population of Ireland in another, 10 per cent. of the population of a city or country were often destroyed during one epidemic.

The most serious array of preventible disease with which we have to contend at present are those which are highly contagious, such as measles, scarlet fever, and whooping cough, and a group of infectious diseases partly communicable, such as diphtheria, typhoid fever, summer diarrhoea, pneumonia, and influenza.

In the control of whooping cough, measles, scarlet fever, there are exceptional difficulties to contend with; these difficulties arise in part from great crowding in tenement houses.

In Birmingham the death-rate from these diseases was reduced from 425 per 100,000 to 72; the decrease was attributed by Dr. HILL to compulsory notification and removal to hospital where necessary.

The past triumphs of preventive medicine have been achieved mainly through cleanliness.

For a long period the death-rate of the British Army in India was 69 per 1,000, as the result of a Royal Commission improvements were made in the housing, clothing, food, and occupation, and the death-rate has fallen to about 14 or 15 per 1,000.

SANITARY AUTHORITIES IN RELATION TO THE MEDICAL PROFESSION.

THE attitude of the Board of Health of New York City toward the medical profession has been in many respects more advanced than that of any other sanitary body in the world. The broad position has been taken that it is the function of the Health Department to furnish to physicians all such specific and general information and assistance in relation to the infectious diseases as can be afforded by thoroughly equipped bacteriological laboratories, in which the work is fully abreast of the most recent observations in scientific medicine. The sanitary authorities of New York City were the first in the world to assume this position, and while their example has been widely followed in the great cities of this country and Great Britain, yet nowhere else has this position been frankly taken and consistently followed to the extent that it has been here. It has been the attempt of the Health Board to introduce new measures or to adapt existing measures to the new requirements of every additional observation with regard to any of the infectious diseases which had a practical bearing on prophylaxis or therapeutics. Two considerations, as I interpret the action of the department, have mainly influenced the Board in the adoption of this position: (1) The desire to extend as rapidly as possible the knowledge of the most recent discoveries in regard to the infectious diseases and the means for their restriction, prevention, and cure. (2) The desire to afford the general practitioner of medicine, without charge, such expert assistance and special information as may be useful to him in clinical work, which could not be otherwise obtained, excepting at greatly increased trouble and considerable expense.

The duties and responsibilities of the sanitary authorities with relation to the general public are numerous and comprehensive. To a very great extent the general welfare of the community is in their hands. Everything which is detrimental to health or dangerous to life, most broadly interpreted, is properly regarded as coming within their province.

Sanitary authorities must protect the community from the individual, "the greatest good to the greatest number" furnishing the first rule of action.

A glance at the functions performed by sanitary authorities shows how broad is their scope: Primarily, sanitary science aims to insure to a community and to each individual an abundant and pure supply of air, light, water, and wholesome food. In the great aggregations of population found in our large cities the preservation of the purity of the air and insurance of an abundance of light and good ventilation involves most comprehensive measures relating to the character of the habitations—their cleanliness and the abundance of their surroundings, including the streets; the provision of efficient plumbing; good sewerage; sufficient air-space to the individual, that is, the prevention of overcrowding; protection against noxious vapors or odors arising from offensive trades, slaughter-houses, gas-houses, decomposing animal and vegetable matter and the purity of the atmosphere, so far as suspended solid particles are concerned.

The public, and even the medical profession, have not yet fully learned the lesson, though it seems almost axiomatic, that different diseases require to be controlled by different methods, and the more accurate and extensive our knowledge of the nature and causes of the different infectious diseases, the more unlike become the intelligent measures devised for their prevention.

THE PHYSIOLOGICAL ACTION OF CHLOROFORM.

SAYS the *Lancet*:—"There is no doubt that in spite of the vast amount of valuable work which has already been done to elucidate the mode in which chloroform affects the body, there are still many questions connected with its action which require further elucidation. Dr. KEEFE of Springfield, Massachusetts, published at the Berlin Congress, 1890, his criticisms upon the much-discussed theory of chloroform syncope. He has more recently issued a pamphlet in which he discusses some of the views recently advanced. Dr. KEEFE contends that death in early anesthesia, or as he prefers to call it 'before complete sopor,' is frequently caused by respiratory arrest, while in later stages of anesthesia death arises from cardiac syncope. This view is opposed to the commonly accepted idea that cardiac syncope may occur quite early, while arrest of respiration usually results from accumulation of the drug in the blood. Death in ordinary anesthesia results, he thinks, from the action of chloroform upon the nerve endings in the lungs and principally upon the medullary centres rather than upon any direct action on the circulatory or respiratory organs themselves or upon the muscular fibre contained in them. Dr. KEEFE has performed some experiments which lead him to believe that cardiac failure in the lower animals always occurs in the 'post-soporose period.' The fact that Dr. KEEFE has not published details or photographic records of his tracings lessens the weight of these findings as against those of others who have arrived at contrary conclusions and have kept a careful record of their research. Indeed, it must be admitted that in the present stage of the controversy what is required is rather experimental work than a *priori* reasoning upon the conclusions of others. It is of great moment in all complex inquiries such as that which Dr. KEEFE has undertaken that not only the conclusions should be in our hands, but the full evidence upon which the conclusions are based. Dr. KEEFE's views are distinctly interesting and novel, and we shall welcome a fuller account of them, especially if accompanied with details of his experiments and reproductions from photographs of his respiratory and circulatory curves."

KASHMIR MEDICAL MISSION.

We have received an admirable little Report of this mission, the work done by it in 1897, and of the general progress that has become so marked in Kashmir.

"The Mission Hospital," we read, "forms one of the most important public buildings in Kashmir."

"Year by year it has increased in size to enable it to cope with the demands made upon its accommodation and resources by an ever growing multitude of patients. During the past year 86,488 visits from out-patients have been recorded, 1,886 have been taken into the wards of the hospital as in-patients and 44,324 meals have been supplied free. The large number of surgical operations, 8,876, shows how far the confidence of the people has been secured."

"Seven hundred and ninety-four eyes were operated upon for entropion and trichiasis. The total of eye operations comes to 1,198. Of these 88 were for cataract. We still adhere chiefly to the *von Graefe* method of extraction, occasionally, however, omitting the iridectomy. Extraction of the lens in its capsule is sometimes done, chiefly in those cases in which the nucleus is small. Bone operations (167) always bulk largely in our list. More than one-third of these are for disease of the tibia, osteitis, epiphysitis or varying kinds and degrees of necrosis."

"About 96 per cent. of our cataract operations were successful."

The State Leper Hospital has been making steady progress. In Kashmir there is no compulsory segregation of lepers. Those who come to the hospital do so voluntarily and stay just as long as they like.

The following table shows the gradual increase in the number of those admitted to the hospital:—

Year.	Total in-patients.	Average number of beds in constant occupation.	Deaths.
1891 ...	63	11	1
1892 ...	55	14	2
1893 ...	82	15	2
1894 ...	89	23	...
1895 ...	108	30	...
1896 ...	118	35	...
1897 ...	141	45	5

PROPOSED LONDON MIDDLE-CLASS HOSPITAL.

The *British Medical Journal* says:—"We have received a circular letter from the 'Secretary, Middle-Class Hospital Committee, 44, Southampton Buildings, W.C.,' stating that a movement has been set on foot for the establishment in London of a hospital for middle class patients, able and willing to pay a moderate residential fee. The circular states that there is at present no alternative between paying from five to ten guineas a week for private accommodation, or 'having recourse to the common ward so repugnant to people of independent spirit.' The appeal now made 'to the wealthy and middle classes' is for charitable help to the extent of providing the initial funds for founding the institution which it is believed would be entirely self-supporting, if not even financially prosperous. Provisional guarantees and promises of support are invited. It is added that subscriptions have already been promised, and that several eminent physicians have expressed their fullest sympathy with the project, which, however, is yet only in the 'theoretical stage.' We readily respond to the request to bring the project to the notice of the medical profession, but the information before us is not sufficient to warrant any expression of

opinion as to its merits. These will depend upon the nature of the regulations for admission, and about this vital matter nothing is said. The idea seems worthy, at any rate, of public discussion, if it is understood that admission to the hospital is to be limited to cases in which the emergency is grave, and the relative poverty of the patient adequately vouched for. But if these essential points are not secured, this proposed middle-class hospital would only add another to the sham charities with which London is infested."

MEDICAL MEN AND CHEMISTS.

We learn from the *Medical Times and Hospital Gazette* that large posters are being placarded in some of the principal towns of Lancashire warning the public against quacks, in which this reference to chemists occurs: "Chemists are not allowed to prescribe for diseases, they are only licensed to sell drugs, &c." The above and the following note in the same paper show how some medical men regard chemists:—

"A medical man, who practices at a fashionable southern sea-side resort, writing on Christmas Eve, says:—"I have recently had two cases of pericostitis treated by chemists, who called it influenza. They are clever men these chemists; just fancy standing behind a counter, not even touching the patient, and being able to tell all about his ailments. Röntgen is not in it. I suppose it is the background of gold-labelled bottles that gives such powerful light. 'Fools rush in where angels fear to tread.' We rarely see a chemist's legs, unless he comes round to us or descends to our level in order to examine a patient.' He is anxious to know if anything can be done to check the practices of these reckless diagnosticians. The most effectual means I am acquainted with of keeping chemists from going beyond their province is to hold them responsible for the consequences of their blunders. If through the ignorance or neglect of a chemist a person's illness be prolonged, or he suffer injury to eye or limb, the person so injured could claim a substantial sum as damages. Let a chemist be mulcted in, say, two or three hundred pounds for his blunders in prescribing, and he probably will afterwards confine his medical administrations to the members of his own household."

THE PRESCRIBING OF ALCOHOL.

We give the following extracts from a pamphlet issued by the National Temperance Association, which convey a useful warning, and one which the wise physician will do well to bear in mind:—

"I do not expect that he shall look upon his patient simply as an organism, however complex and interesting, and confine his studies and endeavours to skilful handling of that organism or mechanism so as to retain it in, or restore it to, perfect working order.

I do not expect that he shall risk the upsetting, by careless prescription of alcohol, of a man's newly-acquired habits of self-control, nor yet the awakening of a dormant, perhaps unsuspected, inherited appetite for the drug. But I do expect that he shall, where possible, make himself acquainted with the personal, and even parental, antecedents of his patient; and I do entreat him, where that is, as it must often be, impossible, to keep on the safe side and keep off the administration of alcohol unless his science utterly fails him in finding another and efficient remedy."

"We would not trespass upon your professional judgment, or oppose our partial knowledge to your fuller culture. I, personally, ask only that, knowing the action of alcohol, its wonderful witchery, its ever-strengthening spell, its terrible power—as a source of disease, as a moral tempter, as

a destroyer of virtues, as a degrader and animal poisoner—you should avoid it to the utmost, and, even if you will not lay it entirely down, that you should jealously guard it from ignorant and unsuspicious hands."

SURGEON-COLONEL A. CROMBIE, M.D.

A CORRESPONDENT writes:—"In your last issue you commented on the official life and work of Dr. CROMBIE. You practically summarised his term of Indian service as a failure. Now I do not think Dr. CROMBIE can be pronounced a failure. First of all, he held many excellent civil appointments. He rose to the rank of Brigade-Surgeon Lieutenant-Colonel. He made a pile of money as a general medical practitioner in Calcutta. Any one who

sees the resemblance of "our dear departed" in the following sketch, will observe from its clear and distinctive outlines, that its subject was burdened with many cares, further that erudition and an emollient disposition are well delineated. I send these few lines and this sketch, as a simple but determined protest against your remarks on Dr. CROMBIE."

We very humbly apologise to the subject of the sketch for our imperfect appreciation of its deep and hidden qualities of heart and soul. We generally speak of men as we find them. We prefer to call "a spade a spade," and after due and careful consideration of all we wrote of Dr. CROMBIE, we do not feel disposed to alter our word picture of him, however much it may differ from the physiognomy of our correspondent's sketch. We say without hesitation, however, that the sketch in no way depicts Dr. CROMBIE's truly imposing figure and personage. He was a tall and handsome man, and in this opinion we think we may well expect the complete and cordial concurrence of his rotund confrère, who among his many sided proclivities as a general practitioner, lord high chancellor of midwives, secretary and electioneering obstructor, adds the very enviable qualification of senior showman of the India Club. We omitted to breathe the fervent hope that Surgeon-Colonel CROMBIE may live healthily and long to enjoy his handsome pension as a military officer in civil employ, especially for his service, "with the colors"! We emphasise that sentiment now.

STRAITS SETTLEMENTS BRANCH OF THE INDIAN MEDICAL ASSOCIATION.

THE usual monthly meeting of the Straits Settlements Branch of the Indian Medical Association was held on the 16th March at 8-30 P.M.

The members present were Messrs. A. B. LEICHTNER, W. R. ARNOT, J. A. REARDON, H. J. GIBBS, W. A. ABRIA, R. A. WALKER and C. J. BATEMAN.

Mr. J. V. PESTANA was unable to attend owing to his being on duty for the night.

The Honorary Secretary read the circular calling the meeting and the minutes of the previous meeting which were then confirmed.

Mr. ABRIA read his paper on the malpractices of native midwives, for which he was accorded a vote of thanks by the members. Question papers on medicine and midwifery were next set to the members by Messrs. PESTANA and BATEMAN.

Owing to want of time, the papers on dislocations of the shoulder were not gone into, and it was resolved that they should be postponed to the next meeting. It was also resolved that there be an interchange of questions between Singapore and Penang, and that the members for Malacca be asked to contribute 50 cents a month towards defraying the cost of the *Lancet*.

It was decided that the following subjects should be discussed at the next meeting:—

Medicine.—Plague and Cholera.

Surgery.—Dislocations of shoulder.

Midwifery.—Normal labor, the puerperal state and its management.

A. B. LEICHTNER, Chairman.

H. J. GIBBS, Honorary Secretary.

The Editor would be glad to have Dr. Abria send his paper for publication in the *Record*.

A CASE OF COMBINED INTRA AND EXTRA-UTERINE PREGNANCY AT TERM.

ROYSTER (*American Journal of Obstetrics*) reports that a negress, aged 34 years, was delivered by a midwife of a healthy male child. Forty-eight hours afterwards, inasmuch as the midwife felt in the abdomen another child which she was unable to deliver; she sent for a physician who, by introducing his hand into the uterus, made out that a living fetus at term was outside of this organ. He advised operation which was refused. The fetus lived more than a week, and then movements ceased. One week later, as the woman's temperature had begun to rise and death seemed imminent, she consented to operation. Celiotomy was performed and a female child, weighing four and one-half pounds, was successfully removed. The placenta with its membranes was attached to the anterior abdominal wall, and it would not have been necessary to open the peritoneal cavity in order to remove the whole. This was done, however, accidentally. The patient recovered. The history in this case reveals the fact that during the third month of pregnancy, while squatting down to pass urine, the patient had had a sharp pain in the right side which caused her to call for help. She fell, fainting, and was carried into the house and put to bed, but recovered within a few hours. There was no external loss of blood.

THE UGLY FAMILY.

We regret that space does not permit us to do more than briefly notice a very able and interesting lecture given under the above title, by Mr. P. DURAISAWMY MUDALIAR, under the auspices of the Srivilliputtur Reading and Lawn Tennis Club.

The ugly family referred to is the family of Narcotics, and Mr. MUDALIAR had some apt and weighty remarks to make upon the many evils they are responsible for. As he justly remarks, "it requires a sound discretion to learn the fundamental principles of hygienic rules." "Narcotics," he says, "are employed as medicines or administered with a view to induce sleep or alleviate pain, when in the hands of a skillful physician, a drug that can do this must be of value

but in the hands of others it may become a weapon of danger."

The narcotics treated of are alcohol, opium, tobacco, ganja, chloral hydrate and cocaine, and the evil results due to their use are clearly set forth.

The lecturer dwelt at considerable length on the progress of the Temperance cause in India, and eloquently urged its many advantages upon his hearers. We have much pleasure in wishing all success to the Temperance cause and such able advocates as Mr. MUDALIAR.

THE MEDICAL INSTITUTIONS OF THE TOWN OF MADRAS.

SAYS the *British Medical Journal*:—"These are fourteen in number, and include general and special hospitals for Europeans and natives. The special hospitals are for women and children, eye diseases, leprosy, and venereal diseases; 17,805 in-patients and 168,348 out-patients were treated during the year, the death-rate among the former being 4.92 per cent. The proportion of men, women, and children treated were 50, 33, and 17 per cent. The transactions of these hospitals, administrative and professional, are recorded in great detail by Surgeon-Major-General Sibthorpe and the medical officers in charge. The work done is evidently large in amount and excellent in quality. Brigade-Surgeon-Lieutenant-Colonel BRANFORTH's report of the Maternity Hospital is, as usual, very able, exhaustive, and interesting. The year 1896 was a healthy one, and free from epidemic visitations. Nevertheless, the attendance of patients was not diminished, and medical, surgical, and obstetric relief sought without abatement. Venereal diseases constituted 305 per cent. of the total treated. The voluntary general hospital is eagerly resorted to by diseased females, but they seldom come until disease is well advanced, and often leave before a cure is completed. The preventive value of the institution is, therefore, inconsiderable. These hospitals are worked at a cost of about 4½ lakhs of rupees, of which Government contributes over three-quarters.

QUARTERLY REPORT OF THE PENANG BRANCH OF THE INDIAN MEDICAL ASSOCIATION.

1. SEVEN meetings were held during the quarter ending 31st March 1898
2. The following members were present at most, if not at all, the meetings, viz.—Messrs. J. F. CARNEGY, J. W. W. HOGAN, F. RODRIGUES and M. E. SCRIVEN.
3. Mr. NORRIS of Butterworth attended the meetings twice and Mr. C. T. DESOUZA of Balik Pulau once.
4. The subjects taken as for discussion during the quarter were—Fever, puerperal fever, water, diseases of the brain, diseases and injuries of the shoulder and hip-joints.
5. The following resolutions were passed—
(a). That weekly meetings be held on Thursdays at 4-30 P.M. in order to discuss on certain diseases and injuries.
(b). That the Association should subscribe to the *Indian Medical Directory*, *The Practitioner* and *British Medical Journal*.
(c). That five days be allowed to each member for the perusal of a journal.
6. Mr. J. F. CARNEGY exhibited a case of osteoarthritis with dislocation of the shoulder joint, and a case of artificial anus of one month's duration in a subject of scrofula hernia, in which the gut was severed by an injury to the scrotum.

THE PRICE OF NATIONAL HEALTH.

SAYS the *British Medical Journal*:—"The subject for discussion at the monthly dinner of the 'Aristo-Club' on

Wednesday, 2nd March, was 'The Price of National Health.' The subject was introduced by Mr. WEAVER DUFFIELD, M.A., London, who pointed out that a statistical study of the subject showed that if the value of life were reckoned on Dr. FAIR's estimate, a total minimum loss of over £10,000,000 was incurred by the nation from deaths due to preventable disease, an amount which exceeded in value the whole spirit trade of the United Kingdom and was double the trade in copper. Dr. ROBERT SAUNDY, in opening the debate on the address, pointed out that it was a mistake to suppose that the resistance of civilised was less than that of uncivilised nations. The latter lived on the verge of starvation, and when they were attacked by zymotic disease the mortality was usually enormous. The evils of zymotic disease were far greater than would appear from consideration of the chairman's figures, for in addition to the immediate, there was a subsequent mortality accounted for by the power of such acute attacks to set up chronic organic disease."

UNRIGHTEOUS GOVERNMENT IN INDIA.

THE C. D. ACTS AND OPIUM.

THE recently issued Annual Report of the Canadian Baptist Foreign Missions contains the text of the Resolutions of their late Annual Conference, among which are the two following, unanimously adopted, on matters of supreme public importance—

I. This Conference would put itself on record as most emphatically opposed to all legislation that ignores the Seventh Commandment. We believe that British soldiers should not be guarded from the results of sin by any such legislation, but that, on the contrary, they should be taught to abstain from impurity, and we urge that provision should be made to allow more of them the blessings of family life.

II. This Conference views with deep sorrow the continuance of the terrible traffic in opium, carried on by the Government of India, in this land, and also in the Empire of China. While regarding the traffic as an abomination wherever engaged in, we cannot hide from ourselves the added hatefulness that comes from forcing such deadly doings on a neighbouring people in spite of the opposition and entreaties of their rulers. We pray GOD to awaken His people in Great Britain and India, in regard to this iniquity.

A GRAVE PUBLIC DANGER.

THE following letter appeared in the *Daily Telegraph*. We quote it because it so exactly bears out a recent article which appeared in our columns:—

"TO THE EDITOR OF 'THE DAILY TELEGRAPH'"

SIR,—Having just escaped a serious accident, will you kindly allow me space in your columns to describe it for the good to the public?

I am nine-tenths of the younger women of the day I have been using xylonite (imitation tortoiseshell) combs to keep back my hair, quite unconscious of the risk I thereby ran. But a few days ago I was kneeling in front of an ordinary sitting-room fire and within five minutes the heat ignited my comb, which flared up, setting my hair on fire, only the prompt action of a brother, who threw a rug over me and stifled the flames, saving me from being severely burnt. We had some difficulty in disentangling the remnants of the comb, which burnt rapidly, destroying all the hair near it and also burning the skin itself.

Considering the extensive use of these combs by all classes and their very inflammable nature, surely legislative action should be invoked to restrict, or even prohibit entirely, their manufacture and sale.

Yours, &c., OWEN RUSSELL."

BAD PAYS MEDICAL OFFICERS.

Bad Pays *the Recorder*.—With reference to the question of the salary and allowances of the 100 medical officers on duty at plague examination camps, it is to be noted that police officers get an additional Rs. 200 a month for this work, and it is to be remembered that this amount represents to them so much pure gain, while the medical officer, withdrawn from civil employ, loses all his other allowances and private earnings. We have already drawn attention to the fact that combatant and military medical officers, who do not sacrifice so much, get in return Rs. 200—or exactly double the honorarium paid to their civil confrères. It will be conceded that the work done at the plague examination stations is of a most important character; the least carelessness might result in the importation of the plague into Calcutta, with consequence to the inhabitants and the trade of the metropolis not pleasant to contemplate. Under these circumstances it is not too much to ask the Government to rectify a genuine grievance affecting men on whose shoulders rests a very heavy responsibility.

PROPOSED MEDICAL SERVICE FOR THE CROWN COLONIES.

THE Committee elected at a public meeting, held at the Imperial Institute on 2nd March 1898, to deal with the desirability of establishing a medical service in the Crown Colonies, met for the first time on 21st March. The Committee consist of Sir Joseph Fayrer, Bart. (Chairman), Sir Wm. des Voeux; Sir Guyer Hunter; Sir Dyce Duckworth, Surgeon-General Reade, C.B.; Dr O Chadwick, C.M.G.; Dr J. Anderson, C.I.E.; Dr V. Corbould; Dr W. Felken; Mr. John Furley; Dr. H. P. Hawkins; Dr. A. P. Hillier; Mr. A. Keith; Dr. H. M. Murray; Dr. H. W. McLeod; Mr. T. H. Richards; Dr. W. J. Simpson; Mr. W. G. Spencer; Dr. G. Thin; Mr. J. G. Turner and Mr. J. Cantile (Honorary Secretary). The Committee drew up the following resolution, to be forwarded to the Secretary of State for the Colonies:—"That it is desirable to organize the Colonial medical services on lines parallel to the other public medical services."

CONDEMNING THE CALCUTTA MUNICIPALITY AND SUPPORTING THE GOVERNMENT.

AT the last meeting of the Council of the Imperial Anglo-Indian Association, Letter No. ¹⁸⁹⁸ ₃, dated 25th March 1898, from the Secretary to the Government of Bengal, Municipal Department, forwarding copy of Bill to amend the Calcutta Municipality Consolidation Act of 1888, was read and considered.

After discussion the Council *Resolved* that in view of the past failures of the Calcutta Municipal Corporation, and in view of such failures being clearly attributable to the absence of a suitable European representation on that body, the Directors of the Anglo-Indian Association hereby record their hearty approval of the proposed Municipal Bill, and they further desire to express their thanks to the Bengal Government for the able and careful manner in which the Bill has been drafted. A copy of this Resolution is to be forwarded to the Bengal Government.

DEATH OF A PROMINENT MAHOMEDAN DOCTOR.

THE *Pharos*, of Karachi, says:—"Death has been rather busy amongst us owing to the recrudescence of the plague, and one of our greatest and best-known men has now gone to swell the roll of its victims. It is with extreme regret that we announce the death from plague of Dr. J. F. MINNA, the Acting Turkish Consul for Karachi. Death was as sudden as it was unexpected, and it laid the victim low in a very few hours. The unpleasantly event took place on the night of Thursday last. In the death of Dr. MINNA the Mahomedan

community of Karachi have lost their most prominent leader, and the most self-devoted and enthusiastic worker in their cause. His place will be hard to fill. Peace to his wishes. We condole the bereaved family of the deceased from our heart of hearts."

UNREGISTERED MEDICAL PRACTITIONERS.

SAYS *the Chemist and Druggist*:—"In the Queen's Bench Divisional Court, on 31st March, Mr. JUSTICE WACHMAN applied, on behalf of the General Medical Council, for an order calling upon the police magistrates of Westminster to show cause why the magistrates should not hear and determine a complaint made against Wm. MAUNSELL COLLINS, under the 40th section of the Medical Act of 1858, for wilfully and falsely taking and using medical titles implying that he was registered under the Medical Act. The magistrates refused to issue a summons on the ground that there was no obligation upon a medical practitioner to be registered, and that the continued use of the title, after having been struck off the register, was no offence under the Act."

Their Lordships granted a rule nisi.

IMPORTANT NOTICE TO DEFAULTING SUBSCRIBERS.

OUR Manager regrets being compelled to notify **BAD PAYS** by a new method. He is tired of old methods, as **BAD PAYS** thrive on secrecy. He notifies that subscribers to the *Record*, who have not paid their dues for over three years, will have their amounts notified to them through the *Record* in a regular list. He gives one full month's notice of this threat, which will be put into execution on the 1st May next.

The above notice has not been put into force with this issue of the *Record* as a large number of defaulting subscribers have paid their dues, while others have asked for a short period of grace. The Manager therefore desires to postpone publication of defaulters' list for one month.

PAPAW AND PAPAIN.

THE *Produce World*, in recommending Indian and Ceylon planters to go ahead with the cultivation of the papaw-tree, says "the pepsine derived from this fruit is the foundation of most medicines for curing digestive derangements, and is now quoted at 8s per lb." We hope the planters will not be misled by this. Papain is not pepsin, and is not largely used in Western medicine; but there is a big field for it in India where caste prejudice prohibits the use of animal products such as pepsin.

THE CLEANING OF SPECTACLES.

SPECTACLES and eyeglasses should be kept perfectly clean and clear, otherwise the eyes will be strained and injured. A well-known optician says glasses and spectacles should be placed in a wash-bowl and soaked in warm water. Then they should be washed with soap and rubbed with a soft nail brush. Polish them with tooth powder and give them a final rub with tissue paper. A few drops of ammonia may be added to the water in which the glasses are soaked.

BENGALI LADY DOCTORS.

The attractiveness of the medical profession for Bengali ladies may be gathered from the fact that among the forty-six students who passed the recent final or diploma examination from the Campbell Medical School, there are no fewer than seven native ladies: Miss Hemangini Masumdar, Srimati Kiran Soohi Devi, Mrs. Bidyalata Mallick, Srimati Nirmalesunder Das, Miss Probodh Bala Pal and Miss Hari Das Mallick. The Dacca Medical College furnished only one successful female student, Miss Kundambini Banerji; the Outback Medical School two, Mrs. Anderson and Miss S Rath Saranghy; and the Temple Medical School, Patna, the same number, Mrs. M. S. Sudhama and Janaki Bai.

THE BENGAL PLAGUE COMMISSION.

Mr. E. B. Gardiner, Under-Secretary to the Government of Bengal, in the Public Works Department, is appointed to be Secretary to the Plague Commission, Bengal, *vis* Mr. W. Banks Gwyther, on furlough. The Lieutenant-Governor is pleased to appoint the following gentlemen to be members of the Plague Commission, Bengal:—Surgeon-Major B. H. Charles, *vice* Surgeon-Lieutenant-Colonel J. Lewtas; Surgeon-Captain E. W. Pilgrim, *vice* Surgeon-Major A. W. D. Lenby; Surgeon-Lieutenant-Colonel R. D. Murray, *vice* Brigade-Surgeon-Lieutenant-Colonel J. O'Brien.

SHORT ITEMS.

The will of Mr. Ernest Hart has been proved, and shows personal estate of the gross value of £15,966, and of the net value of £13,114. The executors of the will are his widow, Mr. Stephen Hyam, solicitor, and Sir Ernest Clarke. Mr. Hart bequeathed to the trustees of the British Museum the signet ring of Ananophet, King of Thebes, and he appointed the trust fund of the settlement made on his first marriage to his sisters. After a few legacies to his relatives and servants he left his residuary estate to Mrs. Hart.

The Indian Medical Service doctors are slowly being sent back from military to civil duty, but the demands made by the plague, which is continuing to spread in the Punjab, despite the labours of the army of police and doctors engaged in endeavouring to check its progress, are so heavy, that it has not been found possible to re-open furlough as yet. The matter, however, is becoming urgent, as the number of doctors who have been denied furlough and been compelled to resort to sick leave, owing to broken health, is already excessive.

Sir George Robertson, K.C.S.I., M.C.S., Surgeon-Major I. M. S. the "brave civilian" of Chitral, has written a history of the famous siege from the point of view of one who was actually besieged in the fort. The work will be published by Messrs. Methuen in the autumn. Sir George Robertson, it is well known, is an officer of the Indian Medical Service. He was educated for the profession at Westminster Hospital, and has had a very distinguished career in India.

Professor Robert Koch has sent from Dar-es-Salaam a report of his research on the surra disease of cattle, which he was able to study during an expedition to West Usambara. A series of inoculation experiments have convinced him that though mules are subject to the disease, donkeys enjoy immunity from it. This is important, as donkeys are the animals most useful for purposes of transport in the Usambara district.

The Committee of the Indian Antivivisection Society has addressed a circular letter to the native princes of India asking them to desist from giving their patronage and support to the Indian Princes' Victoria Health Institution on the ground that they should not support an institute where animal life may be tortured and sacrificed with the best intentions imaginable.

We regret to announce the death, on 2nd April, of Professor Salomon Stricker, the distinguished Professor of Experimental and General Pathology in the University of Vienna. Professor Stricker's name has been a household word among students of medical literature for so many years that most readers will probably be surprised to hear that he was only 65 years of age.

Horse-meat was served at the annual banquet of the Kansas City Veterinary College, 5th March. Though the

banquet was elaborate, not a morsel of meat other than horse-flesh was served. From soup to roast it was all horse. The students and faculty of the college, who gathered around the board, made merry and insisted that it was appetizing.

There are many Anglo-Indian missionaries in India. Robert Robinson and Dennis Osborne—India's Spurgeons—shine to the glory of their Master and to the honor of India. But Phoebe Rowe of Mussoorie was a bright jewel among Anglo-Indian lady missionaries. She has just gone to her rest, and her memory is blessed.

Readers will doubtless be pleased to hear that there is a decided falling-off in the number of students entering upon the study of medicine in Great Britain. The number of students registered last year was the lowest recorded for more than twenty years, and was fully three hundred below the average registered during the preceding ten years.

Dr. Patrick Manson of China will commence a course of lectures on Diseases of Tropical Climates at St. George's Hospital Medical School on 17th May. The course is intended for medical men who purpose practising in the tropics or in Eastern Asia. It will be illustrated, as far as possible, by clinical cases and by demonstrations of parasitic organisms.

Brigade-Surgeon H. C. Gillespie, M.D., Army Medical Department, who died at Richmond on 22nd March, was a graduate of the Royal University of Ireland. He entered the army in 1864 and retired in 1884. He served in the 70th Regiment, and in the Afghan Campaign of 1878-80 (medal).

Deputy-Surgeon-General Henry Cayley, F.R.C.S., formerly Professor of Military Medicine in the Army Medical School, Netley, has been appointed to deliver a course of lectures on Tropical Medicine at the Middlesex Hospital Medical School during the coming summer session.

On the motion of Dr. Blaney, the Bombay Medical and Physical Society have adopted a Resolution, that a congress of the profession be held in Bombay in December to consider the most appropriate means for dealing with plague epidemics in Indian cities, towns, and villages.

Sir William Turner, F.R.S., is elected President of the General Medical Council, as was anticipated would be the case. His eminent fitness for the position had been acknowledged on all hands, and that the Council shared in this opinion is shown by the fact that his election was not opposed.

Surgeon-Captain Moir has reverted from military employ, and his services have been replaced at the disposal of the Bengal Government. It is unlikely, however, that his health will permit of his resuming his appointment at the Calcutta General Hospital at present.

A plague scare has been caused in Calcutta because a few cases uncommonly like plague have ended fatally. No official opinion on the subject has yet been pronounced.

Some blood of these cases has been sent to Mons. Haffkine. There is no Government Medical Officer in Calcutta capable of making a bacteriological diagnosis. So we must wait on Bombay for a stranger's opinion, and on his fiat the fate of our city depends.

Surgeon-Major K. C. Sanjana has been appointed to act for Surgeon-Major Van Geyzel as Chemical Examiner, Madras. The permanent appointment of Dr. Sanjana is District Medical Officer, Tinnavally. Surgeon-Major J. L. Van Geyzel has left for England.

Surgeon-Colonel McGann will be posted shortly as P. M. O., Bangalore, Surgeon-Colonel Branfoot taking his place at Bangalore. Surgeon-Colonel Johnson will take the place of Surgeon-Colonel Bateman as P. M. O., Madras.

Surgeon-General Cleghorn, at present at home on leave from India, and staying at Saint Ives, Cornwall, was thrown off from his bicycle and found lying on the road in an unconscious condition. The latest report is he had not received any severe injury and was doing well.

Mr. J. Tempest, M.D., U.S.A., F.C.S.M., of Oswald-whistle, was sued under the Apothecaries' Act on 7th March and mulcted in the penalty of £20 for practising as an apothecary.

The following have taken the degrees of *Doctor of Medicine* and *Bachelor of Medicine* and *Master in Surgery*, Aberdeen, respectively:—William Cardiff Hossack, M.B., C.M. Poona, and Edward Wood-Mason, Calcutta.

Professor Esmarch of Kiel, one of the veterans of surgery, intends to retire from his professorship very shortly. Esmarch is 75 years old, and has held his chair at Kiel for more than forty years.

In infants, according to Eustace Smith, pain in the head is indicated by wrinkling of the brow; pain in the chest, by sharpness of the nostrils; abdominal pain, by a drawing of the upper lip.

Surgeon-Colonel Maxham, lately Principal Medical Officer at the Cape, succeeds Surgeon-General Walsh as Principal Medical Officer, Bengal.

Surgeon-Major J. B. Gibbons, Superintendent of the Campbell Medical School and Hospital, Sealdah, is allowed privilege leave for three months, from the 26th April.

Surgeon-Captain H. W. Elphick, A. M. S., who was assaulted during the recent plague riot near Hardwar, is seriously ill.

We notice in the list of passes of the First Professional examination of the Edinburgh University that Mr. Maung Ba, a Burmese student, has passed in chemistry.

The Belgian Government offers a prize of \$10,000 to any one who will discover a chemical that will take the place of phosphorus in match-making.

A home for the Sisters of the Punjab Nursing Association has been opened at Kamuli. Three lady nurses have arrived from England.

Apostoli claims to prevent cutaneous lesions in skiagraphy by forming metallic circuit with the earth.

Miss M. M. Traill Christie, M.D., has arrived in Calcutta for service under the Bengal Government.

Current Medical Literature.

MEDICINE.

Causalgia.

SILVIO describes two cases in which localised sensations of heat and cold were felt on the external aspect of the right thigh. The author coins two new words for the particular type of disease—namely, "kauma-nesthesia and psychro-nesthesia," but they are clearly allied to the group of cases associated under the name of "causalgia" by WALKER-MITCHELL. The first case was that of a healthy man, aged 44, who was suddenly attacked three years ago, whilst standing, with a burning sensation in right thigh, at first somewhat limited in area, but eventually extending almost the whole length of the thigh; at the same time there was a feeling of deadness in the skin. Sensibility to pain and heat was normal, tactile sensibility slightly weakened. The burning sensation ceased almost immediately on resting the weight of the body on the other leg or on sitting down. Friction over the part drove away the sensation for a short time. The attacks were intermittent, and occurred chiefly during the winter months. In all other respects the patient was quite healthy. Some twenty years ago, he suffered for about a year from a sensation as if drops of water were trickling down the internal aspect of the right thigh. The second case was that of a healthy man, aged 62, who for the last twenty years had suffered at intervals from a sensation of cold along the external aspect of the right thigh, induced, as in the previous case, by standing, and always relieved when lying down in bed. Never any pain or anomalous heat sensations in the affected part. The sensibility to various kinds of stimuli appeared perfectly normal, both in the affected area and in the rest of the body. Massage and thermo-mineral baths appeared to give relief, but did not cure.—*Brit. Med. Jour.*

Syphilitic Jaundice.

SOME attribute this condition to (a) compression by enlarged glands in the portal fissure, others to (b) papular eruptions in the intestinal tract, some to (c) exhibition of mercury, and others to a variety of causes; but WERNER, who bases his conclusions on 57 cases occurring among 15,799 early syphilitics, fixes the frequency at about 0.87 per cent. and thinks that syphilitic jaundice is characterised by (1) its appearance in the early secondary stage, (2) the presence of fresh specific manifestations, (3) the influence of treatment and (4) its sudden development without gastric disturbance. Sometimes the jaundice preceded, at other times it followed, and in others took the place of a relapse; but its intensity varied much, and though it sometimes increased when anti-syphilitic treatment was commenced, it could not be due to mercury, because it reached its acme and rapidly disappeared before the treatment ceased, and hepatic enlargement was not a striking feature while 1.7 per cent. were a typical case. Xanthopala was observed in 6 per cent., and in 44 per cent. the jaundice occurred within 6 months after the infection, while in 82 per cent. there was marked glandular enlargement with cutaneous affections in 36, affected mucous membranes in 32, and affections of both the skin and mucous membranes in 32 per cent. Ordinary catarrhal jaundice may occur in the syphilitic or jaundice may be an early manifestation of cirrhosis of the liver, but the jaundice occurring in either of these conditions or in late syphilis is quite distinct from that of early syphilis.—*Monat. Med. Woch.*

Treatment of Epilepsy.

DR. PAUL FLEWISG states that, by his bromide-opium method of treatment, in a series of fifty cases, he has had six

additional results with omission of attacks for over one-fourth year. All the patients presented the following: (1) long duration of the disease, some over twenty years; (2) other treatment, and particularly by bromides has been without avail; (3) all kinds of psychical phenomena were present, such as weak memory, lack of nerve tone, irritability, morbid fear; (4) a "toxic" constitution, generally with anemia. As a rule, he does not begin with the combined opium and bromides treatment, except in those cases in which the disease has apparently developed through fear, sorrow, etc.; but starts with the ordinary bromide treatment. He uses the opium when bromides do not affect the disease, when bromidism begins, etc. The reasons for the good results of this treatment are as yet not positively known. The writer regards diet, rest in bed, rectal enemata, etc., as important accessories to the treatment. It may be that the opium produces its good effects in overcoming the nervous irritability and the causeless fear of these patients, for most epileptics are psychically perturbed. The patients must be treated as if quite ill, i.e., they must be under the continued observation of the physician and of a reliable nurse.—*N. Y. Med. Rec.*

Treatment of Tuberculosis and other Infections with the Oxytocinase.

NOTHING that when tuberculous peritonitis is subjected to laparotomy, the access of air oxidizes the tuberculin present in the peritonitis into antitoxic oxytuberculin which cures the local and the general tuberculosis. HIRSCHFELDER tried to realize this oxidation outside the organism with cultures of a very virulent tubercle bacillus which he reared in perfectly sterilized bouillon mixed with oxygenated water (ten degree test) of which more and more was added every 12 hours until at the end of 86 hours there was an excess of oxygenated water in the bouillon mixture, which becomes non-toxic in itself but antitoxic in action, provided all the tuberculin is oxidized. Now phthisis being the result not of a pure tuberculosis but of a mixed infection, he sowed the expectorations of phthisical patients and treating the cultures (so obtained) in the same way as those of KOOR's bacilli he obtained a liquid (*oxysepsin*) whose subcutaneous employment was not attended by local pain or fever. The amelioration of the general condition was so rapid and so agreeably astonishing, especially after the combined injection of oxytuberculin and oxysepsin that HIRSCHFELDER believes that this treatment would be very successful in pneumonia, streptococcal infections and empyema.—*N. Y. Med. Jour.*

Beri-beri.

BOLL and LAACH observed two cases of beri-beri in Norwegian sailors who had returned from countries to which this disease is peculiar. BOLL believes that the infection is due to the drinking-water. The two sailors had spent three months in a port where beri-beri was endemic, but no one on board the vessel contracted the disease. During this time they used drinking-water brought from Europe. A month after the vessel had been supplied with water from this port, and when out at sea, the disease showed itself on board.—*Univ. Med. Jour.*

Venesection in Nephritis.

BAGGELL thinks that the importance of the venous stasis in the early stages of nephritis is not generally realized. It is his practice to relieve the pressure in the venous cava inferior by opening the dorsal vein in the foot and withdrawing 300 grams of blood (adult), repeating the operation if there is reason to believe that the renal stasis still persists.—*Jour. Amer. Med. Assoc.*

SUMMARY.

Large Doses of Iodine in Eye Affections.

PACHSTROMER remarks that large doses (3 g. to 25 g. a day) of iodine are often well borne even where the usual doses call forth symptoms of iodism. The first case in which the use of large doses of KI gave striking results was one of orbital tumour, thought possibly to be sarcomatous, which was increasing in size under small doses of KI. Removal of the orbital contents was proposed, but PACHSTROMER was led to try much larger doses of KI first of all; this brought about some shrinking of the tumour in a few days, and the immobile eye became less fixed. Iodide of sodium (7 or 8 g. a day) was now combined with the iodide of potassium, and within a fortnight the protrusion of the eye had so far receded that the lids could be closed. A fortnight later the swelling had completely disappeared. For a time the treatment caused profuse night sweats. Another class of case in which this treatment has been very beneficial is epiaeritis more particularly when there is much thickening, with secondary involvement of the iris and cornea. In paresis and paralysis of ocular muscles similar results have been obtained, but not so uniformly. PACHSTROMER begins straightway with large doses of KI in combination with bromide; 20 g. KI and 75 g. KBr. in 300 g. of water, a tablespoonful directly after meals, three times a day, either plain or in salted water or milk; the dose is increased by a tablespoonful a day till 8 or 10 g. of KI are being taken. After a fortnight iodide of sodium in the same or larger doses is ordered, and continued, perhaps, for several months.—*Brit. Med. Jour.*

Is it ever impossible to pass a Catheter through the Urethra into the Bladder?

DR. BUCKSTON BROWN discussed this question before the Harveian Society at a meeting of recent date. He thought that it was never impossible to pass an instrument, even in the worst cases of stricture of the urethra, unless the urethra had in some part of its course actually ceased to exist. If an instrument was once passed, the case could be brought to a successful issue without any perineal incision, and, that being so, the patient was saved all the risks of hemorrhage and of that terrible misfortune, a perineal fistula. In the most severe cases of prostatic enlargement the urethra was simply tortuous. The difficulties were fully described, and instruments were shown by which they could all be overcome. In no prostatic case was it allowed that the urethra was impassable by instruments, and therefore there was rarely any real need for any form of prostatectomy or for castration. All the other forms of urethral obstruction were discussed, and the question which formed the title of the paper was answered emphatically in the negative.—*Med. Brief.*

Surgery of the Stomach.

M. DOYEN gives his experience with regard to the result of 144 cases of surgical operations upon the stomach. Of these, 66 were malignant and 80 non-malignant. There were 22 deaths in all and 80 of these were in cases of cancer. Of his last 55 cases 50 were successful, 5 of the patients being in extremis when they came under treatment. Gastro-enterostomy is a proper treatment for dilatation and ulcer with or without hæmatemesis. BOUXX's method is the only satisfactory one; it avoids all danger of infecting the peritoneum. M. DOYEN makes use of the linear compression forceps which were originally made for compressing the pedicle of ovarian tumours. Recovery is undoubted in cases of various dyspepsia or where there is obstruction without pyloric stenosis. The patient must lie on his back and

are often mistaken for the latter. The operation is also of great value in the case of patients suffering from intestinal obstruction, hemorrhoids, cancer, after its performance the urinary function is re-established.—*Lancet*.

The use of Gloves in Reconstructive Surgery.

WILKINSON attaches much importance to the use of gloves in surgical work, especially in the examination of cavities such as the vagina and rectum, in dealing with septic wounds during a course of operative surgery on the dead body, and in the performance of any aseptic operation. By this precaution the surgeon may effectually guard both his patients and himself from various dangers, and so prevent in the first place the infection of a fresh and clean wound from the contact of his fingers during an operation on the living subject, and, in the second place, infection of his own fingers by a foul wound or contact with the cadaver. A suitable glove for such purposes must, it is pointed out, fulfil the following conditions: It should be rendered impermeable by the addition of some waterproof substance, either applied as an external layer, or diffused through the whole thickness of its material; such material should be very soft and pliant, and, at the same time, not likely to be readily torn; it should not compress the skin too much, and render the hand warm; and finally, it should be capable of being readily and thoroughly disinfected.—*Brit. Med. Jour.*

Treatment of Empyema.

LEWASOHEW, on account of his success in the treatment of serofibrinous pleuritis by the removal of the exudate and the injection of a like quantity of normal salt solution, advocates the same measures in empyema, except in septic cases and where there are strong adhesions of the pleura. He removes the pus, washes the cavity with the salt solution until the fluid returns clean, and then leaves as much of the salt solution in the cavity as the pus removed. This operation will have to be repeated in five to ten days. Usually the third time effects a complete cure, though it may have to be done four or six times. The advantages of this method of treatment are evident. The duration of treatment is very much shorter; there is no change in the shape of the chest; the pleural layers are not adherent, and the lungs are completely movable, elastic, and can be inflated to the greatest volume which they had before the illness.—*M. T. & H. G.*

Direction in which Cancer of the Breast Spreads.

GEROTA has made investigations to determine the course of secondary infection from cancer of the breast. He finds that the lymph-vessels are intimately associated with the branches of the internal mammary artery. This explains the occurrence of the infection of the retro-mammary glands and the early adhesion of the pectoral muscles; and further, the occurrence of secondary nodules in these muscles. He also found that the glands of the thorax do not have independent sets of lymph-vessels but that there are in intimate relation with one another, which explains the spread of cancer from the right side to the left side, or the reverse.—*Med. News.*

Compression of the Sciatic Nerve.

DR. ABULHADI has improved upon digital compression for sciatica by substituting a double-pad apparatus for the fingers. He has applied it to forty patients: two were improved, six were quite improved and thirty-two were cured. He recommends compression of the posterior cavity beside the point where the sciatic nerve emerges in the thigh. The general condition of the patient and the location of the pain are better criteria for the success of the measure than electric tests or the duration of the affection.—*N. Y. Med. Rec.*

Quinine Sulphate as a Pain-Expeller in Strengthening Labor Pains.

While quinine sulphate has little or no power for inducing labor pains, SURYAN is of opinion that these alkaline contractions have once begun the administration of quinine causes them to become rapid and energetic. He obtained excellent results from its use in all cases of prolonged labor due to uterine inertia. While quinine strengthens the labor pains, it does not tend to induce abortion. Unlike ergot, it causes intermittent, and not tetanic contractions, and may therefore be prescribed without danger during the second stage of labor. Its action begins in about one-half hour; the drug is therefore best given in two doses of eight grains each, within a period of ten minutes. Quinine is indicated if, after rupture of the membranes, labor is unnecessarily prolonged on account of uterine inertia, the mother is exhausted, and there is danger of the child becoming asphyxiated. While quinine has a tendency to produce post-partum hemorrhage, this is easily controlled by massage of the uterus.—*N. Y. Med. Rec.*

Blood Pressure in Pregnancy, and the Catamenia.

JEDOROFF notes that the ovaries not only develop ova, but also secrete a chemical compound which plays a part in general nutritive changes. Hence ovary juice actually remedies constitutional disturbances during the menopause, especially when that change is artificial, being due to removal of the ovaries. Ovarian juice, when administered to guinea-pigs, increases arterial tension and diminishes cardiac activity. The substance extracted from the uterine mucosa, from menstrual blood, and from the mammary glands promotes a diminution of tension and increases in cardiac activity. JEDOROFF inquires if the elevation of arterial tension before the appearance of the catamenia and its fall when they appear do not represent a balance of the influence of the ovary juice and of a less known uterine substance. For the elevation of tension about a week before the flow precisely corresponds with the period of maximum ovarian activity, and therefore with the time when most ovary juice enters the circulation. On the other hand, the fall in arterial tension some four or five days before the "show" corresponds with the period of maximum uterine activity, when the menstrual decidua is developing. Ratzersbach finds that arterial tension progressively increases after the fifth week before term, and remains higher than in pregnancy during the first days of child-bed. For at the end of pregnancy the uterus loses its glands, so that the ovarian function prevails and arterial tension increases.—*Brit. Med. Jour.*

Fatty Degeneration of the Uterus during Pregnancy.

L. M. BOSS, in the examination of three human uteri, one removed at the eighth month of pregnancy and the other two at full term, found the process of fatty degeneration of the muscular fibres in active progress. He asks whether this is a physiological condition, and if it be so, whether it may not explain the wonderful rapidity with which involution of the uterus after labor normally takes place. Further, it may be asked whether in this fatty degeneration there exists an explanation of some cases of inertia uteri in labor. BOSS has attempted to investigate the subject by experiments on animals (tying the uterine blood vessels), but does not regard the results as applicable to the human status.—*Brit. Med. Jour.*

Painful Peritoneal Adhesions.

ARE usually due to inflammation of one of the abdominal viscera, and may be set up by laparotomy, but ROZE JOSE

BERNARD and GORDON (*Lyon Medical*) who were very successful with their cases, refute BRIDEN's suggestion that continuation of the abscess, apart from inflammation, has set up intra-peritoneal adhesions and, quoting their own good results against the objection that operative interference is likely to set up fresh adhesions, advise scrupulous antiseptic precautions during operation subsequent to which active peristalsis of the bowels by means of purgatives and enemata. The diagnosis is difficult and the adhesions are sometimes not discovered till abdominal section for some other reason; and even when their presence is suspected, they may often be allowed to disappear by spontaneous absorption; but if after months of patience the pain gets worse, operation is justified. The pain is variable, thus it may be fixed and continuous and bear no relation to intestinal movements, or it may be intermittent like colic and precede but be relieved by the act of defecation. The adhesions may become more painful during menstruation or produce constipation by interfering with the intestines, or, if attached to the bladder, may cause cystitis and dysuria.—*Brit. Med. Jour.*

Comparative Indications for Classic Cesarean Section and Poirre's Modification.

CARSTENS concludes a paper upon this subject with the following general rules:—1. Cases operated upon at private houses, with poor facilities and by inexperienced abdominal surgeons, should be subjected to the PORRO operation, the extra-peritoneal clamp method being used. 2. Cases of deformed pelvis, perhaps requiring a similar operation in the future, should be subject to the PORRO operation, even if operated upon in a well-equipped hospital, unless the patient decides otherwise. 3. Cases requiring abdominal section on account of removal of tumors only should be subjected to classic Cesarean section if the operation can be performed in a hospital, or in a private house where all proper facilities can be obtained. 4. Classic Cesarean section should also be performed if the patient desires it, no matter what the future may bring forth.—*N. Y. Med. Rec.*

Foreign Bodies in Utero.

DR. MITTERMAIER describes two very interesting and rare cases. In the first case a silk ligature was left in the uterine cavity by an operator after ligating the pedicle of a submucous fibroid previous to its removal. This ligature became a nucleus of infection, causing suppuration, pyosalpinx and septic fever. This necessitated a radical operation, from which the patient recovered.

In the second case a physician, after curetting his patient, made use of a glass catheter for purposes of irrigation. The catheter broke and the fragments could not be got at. MITTERMAIER delivered the fundus through an anterior vaginal incision, split open the body of the uterus with scissors, and thus exposed the uterine cavity in its entire length. Five pieces of broken glass were removed, the incision closed with catgut, and the fundus of the uterus sewed to the vaginal wound. This patient also made a good recovery.—*Post Graduate.*

Nausea of Pregnancy.

ONE-THIRD of all pregnant women are free from morning nausea during the entire pregnancy, and forty-five per cent. remain free from it during the first three months. If it occurs, it presents itself in seventy per cent. of the women in the first month of pregnancy, seldom in the second, third, or fourth months, and very rarely in the fifth and sixth months; in from nine to ten per cent. it begins in the last three months of gestation.—*N. Y. Med. Rec.*

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.

Functions of the Thyroid Gland.

DR. DE CROIX reported to the Academy of Sciences of Paris that he had made numerous experiments to determine the physiological relations between the nerves of the heart and the thyroid gland. He thinks that he has discovered two important functions of this organ not previously known. First, the thyroid gland produces iodothyryl, which accelerates the functioning of nervous centres which regulate the beating of the heart and the circulation of the blood. The function of the thyroid gland aids in transforming the salts of iodine in the blood into an organic compound, which is iodothyryl, and in relieving the nervous centre of an exceedingly dangerous toxic substance. The heart, by the intervention of the nerve filaments that it sends to the two laryngeals, directs the production of iodothyryl indispensable to its normal functioning. Second, the thyroid bodies, situated at the entrance of the carotid arteries into the cranial vault, constitute an apparatus intended as a protection to the brain against the danger of a sudden flow of blood; as the latter are provoked by too great heart action or by a notable contraction of the circulatory vessels. This preservative function of the thyroid glands is likewise ruled by the heart. In occasioning marked dilatation of the thyroid vessels, the heart intervenes as a safeguard of the cerebral organs either (a) in working, so to speak, the sluice gates in case of sudden danger, or (b) in increasing the production of iodothyryl in the case of persistent danger. Two important points in the treatment of goitre resulted from the researches of Dr. DE CROIX. In the vascular and hyperæmic form of this affection, it is necessary carefully to avoid the employment of thyroid product and to have recourse to the internal employment of iodine. On the contrary, the thyroid products will be very useful in cases of atrophy and of stromous cachexia. In cases of immediate danger section of thepressor nerves in the vascular forms of goitre, and of the sympathetic nerve in the atrophic forms, may be tried; but for these atrophic forms, extirpation of the gland will always have a more immediate and lasting effect than section of the sympathetic nerves.—*N. Y. Med. Rec.*

Estimation of Albumen in Urine.

WASSILIEFF says the albumen may be estimated gravimetrically by mixing the urine with four volumes of ninety-five per cent. alcohol, warming the vessel by five minutes' immersion in hot water, filtering off, drying, and weighing the precipitate, and deducting the weight of the ash.

A rapid volumetric method consists in diluting ten to twenty cubic centimetres of the urine (acidulated with acetic acid if alkaline), mixing with two drops of a one per cent. solution of fast yellow, and titrating with a twenty-five per cent. solution of salicyl-sulphonic acid until the brick-red color produced is permanent.

One part of albumen in 80,000 of urine will show a distinct turbidity.—*Treatment.*

Nerve Cells in Alcoholic Neuritis.

In the *Comptes Rendus des Séances de la Société de Biologie*, DEJERINE recently related an interesting observation. A man given to considerable alcoholic indulgence began to suffer at the age of forty-one years from severe multiple neuritis affecting all four extremities. There was considerable atrophy with contractures and general hyperæsthesia. In the course of the next three years there was slow improvement, so that the upper extremities again became normal. The lower, however, remained as before, complete-

ly May 11, 1895, following fair death, caused as a result of cirrhosis of the liver. Microscopical examination revealed considerable alterations in the cutaneous and motor nerves. The spinal cord, examined by NIELSEN, MARCHI's and the WRIGHT PAL method, revealed no alterations in the cells or in any other part, and the case shows that in spite of very great alteration in the peripheral nervous system the anterior cornual cells may remain unaffected in alcoholic paralysis.—*Lancet*.

Amyloid Degeneration.

PROFESSOR LUBARSCH, of Rostock, who has been conducting an extended series of experiments on dogs, rabbits, and guinea-pigs, endeavouring to produce amyloid degeneration, has published his results in the *Archiv für Pathologische Anatomie und Physiologie und für Klinische Medizin*.

As in human pathology, amyloid degeneration does not always follow chronic suppuration even of long standing. Only a portion of the animals revealed amyloid substance in their organs after being subjected to artificial chronic suppuration. In the experiments the chronic suppuration was produced either by injection of oil of turpentine or bacteria, mainly staphylococci. It appears that amyloid degeneration once established may disappear again.

In concluding, the author expressed his thanks to the Elizabeth Thompson Science Fund of Boston for supporting him so liberally in his costly experiments.—*Med. Age*.

Anthrax.

No immunizing substances found in the blood either of animals treated with PASTEUR'S vaccine or of those who had passed through an attack of anthrax. In animals treated for weeks and months with increasing doses of virulent anthrax cultures so that an active immunity is acquired, such protective substances are present in the blood. The serum obtained from a sheep thus treated conveyed a certain degree of immunity when injected into rabbits. Attempts at cure of the disease in rabbits were without effect. In 2 out of 7 sheep in which 100 to 150 cubic centimetres of normal serum from a lamb were first injected, then a small quantity of a virulent anthrax culture, both animals succumbed. Three other animals were given a single dose (50, 100, and 200 cubic centimetres of serum), and later a virulent anthrax culture. All these animals recovered. The sixth and seventh animals were also injected with smaller virulent cultures; later with anthrax serum. Both recovered.—*Univ. Med. Mag.*

Plague Bacillus.

(a). KLEIN describes the characters of the plague bacillus. He was unable to produce any marked immunity in guinea-pigs by the injection of small non-fatal doses of living culture by the blood of a guinea-pig which had twice passed through the typical disease, or by injections of sterilized cultures.

(b). In the same volume BUCHANAN describes his investigations in two cases of bubonic plague which occurred in London in October 1895, ascribing the cause of infection to some plague-infected article among the personal belongings of the victims.—*Treatment*.

Typhoid Bacillus in Milk.

CAUTLEY finds that the typhoid bacillus will live in milk under the conditions that ordinarily prevail in a household. When artificially added in large amount to milk in the natural condition, its presence in the living state can be demonstrated for several days. There is no indication that the organism multiplies under these conditions—in fact, it is probable that the numbers diminish.—*Treatment*.

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

Public Laundries and Infected Linen.

M. VALLIN submits a report on this subject to the Municipality of Paris. In that city, as soon as an infectious disease is notified, a member of the disinfecting staff is sent to the infected house with a bag to receive the linen soiled during the disease. This is removed at stated intervals, another bag being left in its place. The linen is disinfected and then sent to the laundry. Though considerable advantage is taken of this measure (in 1895, 10,000 of such disinfections were made), many have objected to it, on the ground that stains, e.g., of blood or faeces are fixed in the fabric during steam disinfection. This is now obviated by such stains being removed by rubbing and rinsing in water previous to disinfection, which may easily enough be done in the house before the linen leaves it.

But great danger may arise from soiled linen in such diseases as tubercle, suppurations, diarrhoea, etc., which are neither notifiable nor considered by the general public to be infectious. This necessitates certain preparations with all linen sent to public laundries. The most dangerous operation is sorting out the articles prior to washing. He recommends—(1) That the bag containing the soiled linen be washed each time it comes to the laundry, and the clean linen returned in it. (2) The sorting process be done in a separate room cut off from eating or sleeping apartments. (3) Each bag to be opened under a fine spray of water, so as to sufficiently moisten the clothing, and thus prevent the escape into the atmosphere of any dust containing micro-organisms during the process of sorting them out.—*Brit. Med. Jour.*

Water from a Biological Point of View.

WHILE formerly the quality of water as to purity was thought to be a matter of chemistry and determinable by chemical analysis, the whole tendency of modern research has been, as Dr. A. H. VERDER, has shown in a paper read before the American Microscopical Society, to cause the question of the spread of disease through the agency of water to be regarded rather as a biological one. The danger is determined by the presence of certain living organisms and of conditions on which their continued existence depends, and not upon the quantity of them. The smallest possible inoculation may be fatal through their power of self propagation, and there is no fixed dose. But if their growth is hindered by unfavorable conditions, they may become harmless, no matter how many of them there may be. The purification of water depends on the destruction of these organisms or the production of conditions unfavorable to their growth.—*Appleton's Science Monthly*.

Asses' Milk for Infants.

RIC. KLEMM, urges the claims of the once fashionable but of late years much neglected asses' milk as the best food for young infants. Tuberculosis, he urges, unknown in the ass; the milk resembles that of the human female in reaction, in chemical composition, and in its behaviour in natural and in artificial digestion. This similarity is most marked in the character of the casein and in the relative proportions of casein and albumen—a point of the highest importance, and that in which cow's milk differs most from woman's. Not needing dilution, as cow's milk does, the excess of water necessarily given with the latter, and the consequent diuresis familiar to mothers and nurses of bottle-fed infants is avoided. Its only defect is in the lower percentage of fat, which, though not felt in the first three or four months of life, must be compensated in some way later. This question he leaves unsolved; but we would suggest the simple

addition of fresh cream, which, besides the fat, contains practically the whole of the albumen present in the milk, with if the separator be used instead of the old process of skimming, none of the casein. We may take this opportunity of urging that whenever it is deemed expedient to give cream to infants, separated cream should be insisted on, since it is obtained from perfectly fresh milk, whereas the cream does not rise spontaneously so as to admit of its removal by skimming until lactic-acid fermentation has commenced. The albumen, which is the chief nitrogenous constituent of woman's milk, and incomparably more easily digested by the infant than any casein, especially that of cow's milk, is present in cow's milk almost exclusively in the form of the envelopes of the fat globules, by which their integrity and suspension is maintained, until broken in the process of churning, when they blend to form butter.—*Practitioner*.

Dogs and the Public Safety.

ANY law which tends to protect the public from the likelihood of being bitten by stray and possibly rabid dogs should find general favor in this Dog Regulation Bill, as the Government have named their measure framed for this purpose, is an improvement on such fragmentary and spasmodic Acts and Orders as have preceded it. Put briefly it enables county councils to make regulations facilitating the identification of dogs and their owners, and assists the police and the public in getting rid of ownerless and destructive animals, while it leaves to the Board of Agriculture the powers which it had already under the Diseases of Animals Act, 1884. These include the prescribing and regulating of dog muzzling and also the prescribing and regulating of the seizure, detention, and disposal of stray dogs, so that the Board presumably will not only be the sole muzzling authority, but will be able to step in and deal with stray dogs in any place where the local authorities have not taken steps to diminish their numbers. The Board will, we imagine, have the power to order universal muzzling; at any rate it will act with more authority and scientific knowledge than is usually at the disposal of local authorities and, if necessary, upon a larger scale. There are, of course, many matters of detail in the Bill that will be criticized and more carefully defined when the Bill reaches the committee stage, as, for instance, the branding to be allowed for purposes of identification, and inserted presumably for the benefit of hounds, while the arbitrary powers given to the police to diagnose and destroy suspected cases found upon the highway will probably be curtailed, but apart from minor alterations, the Bill is more likely to find public favor and be enforced by the police than the muzzling orders that have preceded it. The practical question of enforcement remains the chief difficulty.—*Lancet*.

Termination of Liability for Care at Hospital.

ST BARNABAS HOSPITAL v. MINNEAPOLIS ELECTRIC COMPANY is the title of an action brought to recover for the care and treatment of one of the employees of the defendant company, whom it had taken, after he had been seriously injured, to the hospital named, where he was received as a patient for an indefinite period, no length of time being mentioned, at the company's request and upon its promise to pay for his care and treatment. Subsequently, and while the patient was yet incapable of being removed or discharged from the hospital without great danger to his life or health, the company gave notice that thereafter it would not be responsible for his care or treatment. Could the company thus terminate its liability, especially at such a time? The supreme court of Minnesota holds not. It holds that under the circumstances it was an implied condition of the contract that the company could only terminate its liability by removing the patient or when he could be dismissed by the hospital without serious danger to his life or health. In order to relieve itself from liability for care and treatment furnished after the notice on the ground that the patient had means of his own to pay for it, the court further holds that the burden was on the company to prove that he had means out of which the hospital could and should have collected its pay. But for the hospital to maintain its action, the court intimates that the burden belonged to it to prove that the patient could not have been dismissed without great danger to his health or life until the date of his dismissal, or that at least it could not recover pay after the notice against the company beyond the time to which it proved that such condition extended.—*Jour. Amer. Med. Assoc.*

TERRAPININ AND FERRATIN.

Ferratin in Anemia.

From 2 to 4 grains of this drug given three to four times daily without any other medicine is highly recommended by BOLLE, who quotes three cases: (1) A girl aet. 13 with simple anemia of a marked degree, was cured in 30 days. The red blood corpuscles ran up from 2,000,000 to 3,000,000 per c. cm., while appetite improved, constipation disappeared, and so also the sensation of fatigue and the cheeks and mucous surfaces were tinged with a healthy red color. (2) In a girl aet. 16, with anemia and constipation for three years, improvement was not noticed till the 21st day under ferratin, and by the 40th day cure was complete. (3) A youth of 17 was had with insomnia, anorexia, headache, and too easy fatigue, which prevented his joining in sports; but 2 grains of ferratin four times daily gradually improved his condition, so that in 30 days his bad symptoms disappeared and the blood count showed the red corpuscles had increased from 2,800,000 to 3,400,000 per cubic centimetre.—*Chim. Med. Rec.*

Decomposition of Iodoform by Light.

WHEN ethereal or alcoholic solutions of iodoform are exposed to light, decomposition takes place, the iodoform being gradually decomposed and the solution becoming brown and losing a good part of its therapeutic value; but FLAURY notes that after a time the action of light appears to be nullified, because the change in color prevents the violet and ultra violet rays, which are the most active passing beyond the surface, and thus stops further action; but if there be present some body that will combine with the iodine as fast as it is liberated, the decomposition of the iodoform goes on till the whole of its component iodine is liberated. Hence in dressing wounds with iodoform solution metal syringes or douches should not be employed.—*Jour. de Pharm. et de Chim.*

Potassium Bichromate as an Expectoant.

In laryngitis and bronchitis Dr. J. E. WEAVER found bichromate of potassium very useful, especially when the secretion is stony and hard to raise; but he values the drug most in tonsillitis with a rapid onset when the tonsils are rough, raw and angry-looking with macropurulent exudates from the follicles. In bronchitis and laryngitis he gives a teaspoonful every two hours of a mixture of 1 grain of the salt in $\frac{3}{4}$ of water; but in tonsillitis he adds the finely powdered bichromate to water until the latter is of a dark lemon or light orange shade, and of this solution he gives a teaspoonful every hour till it nauseates the patient when he lessens the dose. For this treatment he claims marked improvement after the third or fourth dose. The drug is also a story antiseptic.—*Med. Record*.

Acute Mania.

R Sulphonal gr. xv.
Sodii bicarbonatis gr. iv.

M. For one cachet. S. From one to three such cachets daily. In cases that are rebellious much larger doses are given.—KADT.

Toothing Powder.

Hydrag. subchlor.,
Pulv. antimonalis,
Pulv. pot. nitr.,
Pulv. smoch. alb. aa. partes aequales.

Dose Under 1 year, 2 gr.; over 1 year, 4 gr.
This is better without the nitre.

Laville's Gout Cure.

THIS patent preparation is said to have the following composition:—

Take of—

Quinine	7-7 gr.
Chinabone	98 gr.
Colocynthis	38 gr.
Lime salts	7-6 gr.
Coloring matter	4-4 gr.
Alcohol	3 i. & dr.
Water	2 i. & dr.
Port wine	124-6 fl. dr.

—National Druggist.

James Cornum.
The following application will be found useful in acute
cornea

Oil of	gr. viij.
Oil of	3m.

To be applied over the nasal mucous membrane after preliminary cleansing of the surface.

Bay Rum.

Ol. myrsine acris	3ij.
Ol. pimentis	m.xx.
Spt. mochari	37.
Spt. vini tenuior, ad	Oj.

M. Corn and Wart Paint.

Ac. salicylic	3iv.
Pulv. resina	3ij.
Tr. cannab. ind. ad	3iv.

This is used by painting on the corns in the same manner as the ethereal corn-cures.

Antiseptic Varnish.

R. Powdered lac	900 grains.
Balsam of Tolu	75 "
Thymol	22 "
Alcohol	750 "
Ordinary ether	1,500 "

M. Filter.

Liver-Mixture.

Ac. nit. mur dil.	5ij. m.xx.
Ext. cinchon liq.	3ij.
Tr. podophylli	3j.
Ext. tarax. liq.	3j.
Glycerini	3j.
Inf. chiretta ad	Oj.

Mix and filter bright

One tablespoonful two or three times a day after meals.

Antiseptic Cream.

Powdered boric acid	1 oz.
Powdered oleate of zinc	1 oz.
Lanoline	2 oz.
White vaseline	2 oz.

Mix.

Therapeutic Brevities.

HÆMOGLOBIN is a pleasant tasting and stable liquid preparation of hæmoglobin.

EPIDERMIC is made by mixing equal parts of white wax glycerin, mullage acacia and freshly distilled water.

ACERDOL, which appears to be pot. permang. containing free potash, is a new disinfectant.

EUPHTALMIN or methyl vinylicac etonalkamine hydrochlorate is a new mydriatic.

IODOGALLICIN, the new bismuth compound of oxyiodo-methyl gallol is a valuable antiseptic powder.

CAPROL and **CHLORALCYANHYDRATE**, which are new chloral compounds with tannin and prussic acid, respectively are suggested as hypnotics, but have not been extensively tested.

OSIN, or ext. osium liquidum is a dark brown bitter tasting liquid, which has given good results in diabetes.

GRINWHA SYLVANSTRAN, common to Assam, is suggested as a means of disguising quinine and other disagreeable medicines, since it has, when chewed, the peculiar property of temporarily neutralising the sense of taste as regards bitter and sweet things, while sour and saline substances remain unaltered.

EMULSIONENYDIN is highly commended as a substitute for potassium iodide every one of whose therapeutic effects it possesses, without any of the evil effects such as iodism, etc.

Correspondence.

THE RIDICULOUS MEMORIAL OF SEVENTY-NINE MEDICAL WOMEN.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—It may be a sign of the times, if so, it is a very unwelcome one, that 79 medical women should separate themselves from the great majority of medical practitioners, and repudiate the traditions of the profession they have joined by entering the political arena and presenting a memorial to the Secretary of State for India, protesting against the measures recently enacted for dealing with venereal disease in the Indian Army.

The importance of this memorial does not arise from the influence, power, or number of the feeble hands by which it was presented, it arises from the fact that behind it is arrayed, all of what Mr. Bismarck would call the unctuous self-righteousness of England. It arises from the unscrupulous manner in which such literature is distributed throughout the length and breadth of the land, amongst Rectors and Curates guiltless of all knowledge of the world, amongst women of all classes, and even amongst unmarried girls.

Were this memorial merely sent to those who could gauge it at its proper value, nothing would ever be heard of it.

Putting all these questions on one side, it is my intention, with your kind permission, to point out in your columns, which are always open to fair comment from whatever side it comes, the utter worthlessness of this memorial.

It is full of fallacies of the worst kind, its statements are untrue, and its inferences illogical.

It would take up too much of your space were I to discuss every point in which this memorial lays itself open to severe criticism. I will therefore content myself with noticing a few, which appear to be of most importance.

This memorial endeavours to show that venereal disease differs in certain respects from other infectious and contagious diseases, so that the methods applied to keep them in check are inapplicable to venereal disease. In the first place the memorial says:—"With respect to venereal disease, it lies to a large extent within the power of the individual to avoid infection. With other contagious diseases there is not the same power of voluntary escape."

Now this sounds plausible enough, but it is untrue to a very important extent, and it is this very point that these 79 medical women totally ignore, or are callously blind to what their natural instincts should have told them was their first duty.

Can the woman who marries a diseased man, without knowing that he is diseased, and thereby contracts venereal, be said to contract the disease voluntarily? Can the children born of a syphilitic parent be said to have it in their power to avoid infection?

The authors of this memorial know that some 8,000 cases of venereal disease are imported every year from India to England; they also know the insidious and terrible results that half-cured gonorrhoea may inflict

upon women after marriage ; but instead of taking every means in their power to protect innocent women and children from these fell diseases, they actually accuse them of being willing participators and of contracting the disease voluntarily.

To sustain the distinction they have set up between venereal and other contagious diseases, they say :—

"Other contagious (contagious of course meaning 'infectious and contagious,' as stated a few lines higher up in the memorial), diseases are, as a rule, easily recognised, rarely or with difficulty concealed, treatment is voluntarily sought, and no question of conduct or character is involved."

Now supposing that all these propositions were true, which they are not, supposing that venereal diseases were very difficult to recognise, that they were frequently concealed and that treatment was not sought voluntarily, surely if such were the case, it would form no argument to permit these diseases to go free and uncontrolled ; on the contrary, it would be an admirable reason for closer and stricter legislative measures.

It is, however, manifestly absurd to state that venereal diseases are more difficult to recognise than typhoid fever for instance, and if it is a fact that the infectious diseases are rarely concealed, and that treatment is voluntarily sought in England, it must be remembered that this is so under compulsion, and that it was not the case until concealment was made illegal, and a law passed, with penalties attached to it, for the notification of certain infectious diseases.

But England is not India, and we have all had a bitter experience of the talents of the native of India for the concealment of all forms of infectious disease.

Now as for the question of conduct or character, I fear that these medical women hold very narrow views, analogous to their view of the word morality, which has no meaning for them except *sexual* morality.

Supposing a person, suffering from scarlatina, or in charge of a scarlatina patient, uses a public conveyance, to the danger of the other occupants, is there no question of conduct or character ? Supposing a person lets lodgings which have just been vacated by a case of infectious disease, without giving information or having them disinfected, is there no question of conduct or character concerned ?

Both these acts are contrary to the law of England, is it not immoral to wilfully break the law and to endanger the lives of others ?

No case can be made out for treating venereal diseases differently, from a legal point of view, to other infectious diseases, the admitted difficulty of dealing with them only renders strict legislative measures all the more imperative.

The only logical position that could be taken up by these memorialists is, that prostitution should be made illegal, as it is an immoral trade and one dangerous to health and life ; this position is however denied to them, and they cannot take it up, because exactly the same arguments could be used against the liquor trade, against "file cutters," "button-makers," "lead-miners," etc., in fact against some fifty different trades, all of which are known to be injurious to the health and to shorten the

lives of those employed in them, but all of which it is impracticable to pronounce illegal.

In these cases the law does not stop the trade, but it takes every possible precaution to preserve the health of the workers. No doubt it is very unpleasant for a person carrying on an unhealthy trade, to have his premises inspected, but in the interests of others, the law considers it necessary, and the law must logically apply the same rules to the trade of prostitution.

Another funny argument used by these 79 medical women virtually amounts to this—it is impossible to stamp out venereal disease ; therefore you should not try to check it. They maintain that "it is practically impossible to say when any woman, who has once been affected with venereal disease, is free from all likelihood of infecting others."

It may be presumed, I think, that French authorities on this subject are quite as well informed as these medical women, and what is their opinion ?

Dr. COMMERCE thus states it, in the *Annales d'Hygiène Publique*, January 1898 :—

(1) "La Syphilis est rarement engendrée par la prostitution réglementaire."

(2) "La Syphilis est presque toujours engendrée par la prostitution clandestine."

These medical women try to make out that soldiers are not properly treated for syphilis. This is utterly untrue, they are treated far more carefully than the same class in civil life ; they spend long periods in hospital at the expense and to the loss of the State, which from the necessity of earning their livelihood is impossible for their civil brethren.

Of all the curious things in this memorial, the most curious perhaps, is the assertion, that when a woman is diseased, it is better for those who consort with her that she should be allowed to go free, and not compelled to stay in hospital. But enough, the purity intelligence is on a par with the purity conscience, and both are alike incomprehensible.

Let these medical women open their eyes and see what is beyond dispute, that there is more sexual immorality in every large town in England, than in any cantonment in India, and that the reason there is less disease is simply that prostitution is more general.

Yours &c., A MEDICAL MAN.

—:O:—

MILITARY ASSISTANT SURGEONS' MEMORIAL.

TO THE EDITOR, "INDIAN MEDICAL RECORD"

SIR,—Amid the various amendments to our wretched Memorial of 8 years back, which have of late received currency in your journal, the last certainly "takes the biscuit," and I trust the following comments arising out of it may be accorded a corner in your columns.

To my poor comprehension a memorial, in order to ensure a hearing, should prove itself to be a genuine and unanimous appeal for the redress of actual and pressing grievances under which the memorialists are writhing ; and not a "crying after the moon," in the hope of wringing from the authorities some trifling or trivial substitute. Such, we earnestly meant ours to be ; and, I venture to say, you, Sir, and our generous supporters believed like-

...this proposal of... and the... and the... of its... And hence, I hold, this policy should be... The memorial in its entirety... should be... If it... every respect and the most reasonable and... of our most pressing needs, then we can accept nothing less—by degrees and instalments if you will, i.e., if the exigencies of the State compel—but without abatement of one single iota!! On the other hand, were it a sham agitation, devoid of just grounds for complaint, except in a mere fraction of its bulk, then we not only deserve to have got nothing, but the movement would have met with severe reproof from the authorities. That it was the former and not the latter is amply proved by the action of Government in the matter, their comments thereon and recommendations to the Secretary of State in Government despatches.

With what bitterness of spirit then, have we looked on at the wreck of our hopes, and the frantic sacrifices of our own men in the disaster. To use a nautical simile, the successive casting away of spars, masts, and rigging till finally we are presented with the appalling spectacle of a clever officer—mayhap despairing of redress for the many, to put the most charitable construction upon his action—calmly and without the least compunction, heaving the sailors overboard, like so many Jonahs, to lighten the unseaworthy hulk that she might bring safely into port, at least the hopes and aspirations of his section of the crew. This policy may be intended to conciliate the powers above—though for the reason stated I doubt its success; but how will it be viewed by his quondam shipmates who form the majority, and on whom the hardships of the voyage pressed most severely? "What care we?" methinks, would hardly be his reply!

I admit one, and only one qualification to my insistence on the memorial in its entirety, and even that is rather in the nature of an appeal to the services at large to renounce a gift we have little reason to be grateful for, than a proposed amendment to our demands. It is on the much vexed question of commissions to subordinates; and coming as it does, after the above comments, it becomes necessary that I should at the outset disown anything in the nature of a spirit of retaliation in advancing my views, for I should be cutting off my nose to spite my own face, and I might be accredited with common sense enough not to be guilty of such folly.

I have long held, and have reason to believe the opinion is fast gaining ground, not only in ours but in all the subordinate services, that the system of granting commissions to subordinates, as at present obtains, is not only a farcical mistake, but a serious wrong from whatever point of view it may be looked at—wrong to the commissioned grades of the army at large, wrong to the individual selected, and wrong to the service of which he may be a distinguished member; and I maintain that it is becoming the burning question of the hour for the unhappy possessors of this distinction with one voice to renounce the hollow sham that it at present is—an honour indeed!

Space will not permit of my going into details here, on the above points, but in a future paper I hope to do so to justify the reform I advocate. The principle in its inception is a just and equitable one, of granting commissions as rewards for special ability and long and meritorious service, but unfortunately it has aborted, and herein lies the objection.

In a word, my point is, such men should be lifted clean out of the subordinate ranks into the executive services, or let alone, as is, and always has been, done in the army. Then we should have a goal we could look forward to with pride, and one worth striving for. At present it is a white elephant.

The argument is clear. If a man is a fit recipient for such distinction, he ought to be able in every way to adapt himself to his new position and be a fit associate for his brother officers, and poor indeed must the service be that could not produce such examples; and per contra, if he is incapable of this, he is not fit for such elevation and should not get it, did his service, partially free from official blemish, extend over half a century! Nay, it would be a charity to himself not to make a gay of him and have him ostracised; and would save everybody else, both in and out of his service, many a pang of humiliation.

Yours &c., A FORLORN HOPE.

(We believe every occasion will be made by instalments.—ED. I. M. R.)

10:

BRITISHERS AND THEIR DESCENDANTS

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—While India is being so strangely agitated about the Anglo-Indian Cause at the present time, it may serve a useful purpose to give prominence to the following remarks from the *Bengal Times*, whose doughty Editor, Mr. E. C. KEMF, is one of the staunchest friends of the cause.—

"Pride of nationality is one of those self-respecting emotions that sends a thrill of conscious superiority through every heart. (*Veni Romanus sum*, embodied a suggestion declaratory of an inalienable, an undeniable right, guaranteeing certain privileges which had prescriptively grown into every Roman citizen's constitution and had solidified with his maturity. For their retention, he would do and dare, he would live or die, and it is noteworthy that, our own laws and constitution, framed after a model enunciated in that 'seven-hilled city's pride' survive to us to-day, in their under deteriorated force and pristine integrity. We do not now refer to that agglomeration of nationalities, we style an Englishman. By pure descent of race and blood, it would be difficult to find any such representative character. A British slander there is, one born in England, hence, an Englishman, it is not difficult to meet, but where shall we look for one descended from an unadulterated origin? Pict, Scot, Scandinavian, Flemish, Norman, Saxon, Dane—all have contributed to produce this being, who, with a natural pride of race and nationality, styles himself what he demonstrably is not—an Englishman! Yet, apocryphal as it may seem, he who combines in himself so many races, is apt to look down with seeming contempt, upon his brother's son, with a suspicion of Oriental parentage in his composition, and to deride him as an inferior—an offshoot from his own pure (?) proud stock! And not only is this absurd exclusiveness manifested in his bearing towards his kinsman, but he must needs invent a designation for him, to widen

still further a gulf having its origin in silly sentiment. His brother's son is not an Englishman—that is a title reserved for himself and such as he, a national composite culminating in racial satire—but a *Eurasian*, a non-descript called into official entity by a caprice. Dr. WALLACE has recently described this operation with cutting sarcasm:—

"Some years ago, a member of the Bengal Secretariat thought he would coin some epithet for the new race of British descendants in India, who were fast becoming a power in the land; so he thought the word '*Eurasian*' would suit, and it was launched in the classical nomenclature of State documents as the name and title of this new race. But its deep and insidious sting was ever felt as a stigma and a curse by the men and women and children who were henceforth to rally round this hybrid standard. This name, once accepted, was intended to alienate the honored designation of '*Britisher*,' and the process of isolation, ostracism and degradation would in time have been rendered complete."

Years flowered on, and this objectionable and offensive term continued to be applied, not only to those of combined race, who showed perceptibly their Asiatic origin, but it had begun to extend itself to all born and reared in India, in whom a tinge of Oriental admixture was scarcely perceptible. But a day of retribution was at hand. Working themselves into positions of trust and emolument, these so-called '*Eurasians*' fairly demonstrated to Government that however meek and lowly minded, however unassuming and non-combative in asserting their claims to State preferment, they had made themselves absolutely necessary to their employers, since there was not a department under Government in which their services could be dispensed with, in any circumstances, without creating inextricable confusion; and as heads of departments felt how indispensable they had become, a few occasional sopas were ungraciously cast to them and a few thickly veneered office memos, compensated them for work their superiors in office could not undertake without their active and zealous co-operation. Dr. WALLACE, in his very able address, thus continues to trace their progress:—

"Finding that the term '*Eurasian*' was not sufficient to politically emasculate our people, another official cynic conceived the idea that the '*Domestic British Community*' should be induced to accept the designation of '*Statutory Natives of India*,' under the seductive inducement that, with the acceptance of this classification of our people, they should lose nothing but rather gain the right of admission to the '*Statutory Civil Service*,' which was about to be inaugurated for the sole benefit of '*Natives of India*.' The so-called '*Statutory Civil Service*' turned out to be one of the biggest shams of the Victorian era."

Doubtless, there was a certain unworthy ingenuity of conception enfolded in this partition of exclusiveness. Covenanted men, who ruled public departments, bethought them that their own sons, nephews, cousins and a host of young enterprising spirits were preparing at home for life's battle, and where could that battle be better fought than on '*India's coral strand*'? These men had dreamed dreams which did not need any Joseph to interpret them. They felt that they had claims of kindred pressing upon them, and since he is worse than an infidel who provideth not for those of his own household, they resolved such a reproach should not attach to them. In these circumstances, distinctions of class, race, education, &c., were brought to bear as levers of exclusiveness for Brahmins, and of disability for their Indian-born and Indian-educated cousins. Besides, India with its strict

caste exclusiveness, had centuries before prescribed hereditary succession, not in ancestral property alone, but in avocation. In London we had a Court of Directors, an India Office and a school of young men but awaiting an opportunity to be shovelled out to India for installation into office then held by their patrician seniors, as warming pans, but destined at no distant date to lapse to younger energy and more vigorous enterprises. Nominations were not difficult to procure, and examinations in those 'good old days' usually limited themselves to tender enquiries as to latest family advices from India—a simple and satisfactory method of conferring qualification, which was not without its advantages. It was demonstrably less vexatious than vulgarly persistent questions in mixed mathematics, natural science, history and those other proxy subjects which irritate our young Civil Service Hons into lashing their tails at Civil Service Commissioners."

Yours &c., SCOTIA.

MILITARY RANK FOR ARMY SURGEONS. SOME SCOTCH OPINIONS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—The two appended letters from that well-known Edinburgh paper, *The Scotsman*, bearing on Military titles and rank for Army Surgeons will no doubt interest your readers:—

I,

Your correspondents all seem to overlook the main point of the dilemma in which the War Office authorities are placed by the refusal of well-educated young medical men to join the Army Medical Department. The question now is, not whether the army doctors are silly or unreasonable in their demands—they may be so, and in my opinion they are so—but the Army Medical Department is an absolutely essential and vitally important branch of the army, and must be kept complete and up to the mark if we are to have a well-equipped army at all.

If your correspondent "*Observer*" really wishes to afford any assistance to the authorities, he would discontinue his silly and useless sneers at the demands of the army surgeons, and would endeavour, if possible, to suggest some way out of the present serious impasse, instead of merely trying to show off his acquaintance with JOHN STUART MILL and his system of logic, of which it is to be hoped he knows a little more than he does of the Army Medical Department. The real cause of the present unpopularity of the Army Medical Service is the abolition of the regimental system, and nothing else whatever. As long as that system was in force, the medical officer shared in whatever prestige attached to his regiment. He belonged to it, was part and parcel of it, and looked on it as his home. Since the regimental system was done away with, the popularity of the Army Medical Service has steadily deteriorated, and the men who now join it come from a lower social stratum, and possess markedly inferior professional attainments.

When I joined the service at the time of the Indian Mutiny, we were called Assistant Surgeons and ranked merely as Lieutenants, and never hankered after military titles or any booh of the sort. Both pay and pension were much smaller than they are at present; but notwithstanding this, the service was sufficiently attractive to highly educated young medical men of good social standing.

Among the twelve or thirteen men whom I more particularly remember as joining the service at the same time as I did, almost all were M.D's. of Edinburgh University. Several, like myself, were members of good Scottish country

families, while all the others were either the sons of military officers of position or of clergymen or professional men of well-established standing.

Men of this class do not join the service now-a-days, and as far as M.D. of Edinburgh University, I doubt very much whether there is a single one in the whole of the British army. I consider the demands made by Dr. FARQUHARSON'S deputation last week as puerile and absurd. Nothing will restore the prestige and popularity of the Army Medical Service except the restoration of the regimental system. The usual reply is that it broke down utterly during the Crimean War. But I should like to know what department did not break down utterly during that disastrous war.

TWENTY-FOUR YEARS' SERVICE.

II.

If not too late before a great mischief (perhaps difficult to repair) is done, will you permit a few lines on the other side of an argument for which the pros are so glibly and often, so misleadingly stated, by the advocates of pure military rank for army doctors.

It is perfectly true that candidates are not forthcoming; true also that the Army Medical Staff has fallen very low in military esteem; and that in military clubs and socially the present representatives of the noble and gentle art of healing are by no means heartily received or cordially welcomed.

Will they be more so if dubbed Colonel, Captain, General and what not?

Obviously, the animus against them will be all the greater and more general, believing, as officers do, that a fit of militarism has already weaned a large number of the doctors from study of their own most worthy profession to seek after the gew-gaws and shallow fripperies of a soldier's life and surroundings, to the manifest deterioration of both their own professional skill and of the estimation which they can only earn by being devoted surgeons and physicians, and by taking a pride in being known as such, without seeking to masquerade under false colors.

So deep would be the disgust of the army if doctors were dubbed Captains, &c. pure and simple, that it is more than probable that officers would cease to use these titles, certainly in social intercourse they would drop them.

The profession of soldier and of physician or surgeon are as wide apart as the poles, and require absolutely opposite qualities, manners, and behaviour.

No soldier denies that the highest courage is required from, and shown by, the military surgeon, and in classing him as a non-combatant there is no imputation on him that he does not more than share many of the risks and perils incidental to a soldier's life. The chaplain and the priest do the same, and as an old ranker said to me, I look on a doctor as next door to a priest.

Where the combatant officer should be somewhat fierce and sharp in manner, the doctor must be gentle; where one is better employed learning the trade of arms, the other should be studious; where one may safely air his ideas and thoughts in the freedom of the mess, the other should hold his tongue as to the whole of his professional work.

In all professional aptitude the doctor in the army has greatly deteriorated since he commenced to ape another profession, until it is now extremely rare for an officer to trust himself to one of them for the slightest treatment if any respectable civil practitioner is available. Socially the medical profession in the army has become intensely unpopular, and I have seen letters from surgeons written to claim invitations to entertainments as a right, when these

have not been voluntarily offered! The attempt to scale the heights of social popularity by force and Royal Warrant is now being made, though Lord HASTINGTON expressly stated, sensibly enough, that this could not be secured by any possible abuse when he was pictured on the point as Minister of War.

The road to higher consideration and more appreciative treatment is in quite the opposite direction to that which the doctors are now taking, and their course, even if facilitated, can only land them in a deeper slough than that they now occupy.

It is somewhat remarkable that in the sister service of the navy, where the necessity of maintaining a constant and strict discipline cannot be shirked, there has been no demand for doctors to be called admirals and commodores. The reason is, of course, obvious; that not far one moment in the navy could the whole and sole command of the captain over every department within his ship be questioned.

In the army the importance of command is not so obvious in peace time, but it becomes so in war, and the functions of command are as necessary to the young Lieutenant in charge of a detachment as they are to the General of division.

In no case could they be shared with the doctors.

If this proposition be true, the attempt is merely being made to obtain a fictitious and nominal rank for purposes of display.

This will gain the doctors no increased consideration, and the pursuit of this object will further wear them from their professional duties and the respect that the conscientious and devoted discharge of duty invariably brings, and to no one more than the good army surgeon.

There is a ludicrous side to this distressing subject, which was well brought out by the late Sir GEORGE OSBENNY, a past master of the art of policy, both military and civil. Relating how NAPOLEON would not allow even the rank of Lieutenant-Colonel, lest the dignity of real Colonel—the commander of a regiment—should be infringed, and how that great leader refused to acknowledge a regiment without its colors and its Colonel, even sending one corps back to retrieve its dead Colonel from a village whence it had been driven, Sir GEORGE passed to the question, "Where is your Colonel?" If it had been asked in our own service, answering it humorously enough, "The Colonel is making a poultice—"

Doctors claim that we have long fallen away from so high an ideal, and this is true, but two wrongs do not make a right, and if discipline has been already injured by some rude shocks to military pride and the cheapening of rank, surely this is in itself no reason why a deadlier blow still should be dealt, and such the proposal, paltered with by Lord LAIRDOWNE, would undoubtedly be.

Yours &c., Y.

—:O:—

BOGUS INDIAN PRACTITIONERS: KABIRAJES AND THEIR FRAUDS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Two kinds of deception have now become most prevalent in India. One is deception in religion and the other is deception in medicine. As many cunning religious preachers make fortunes by their *gairis* dress, deceitful practices and eloquent lectures; so many uneducated *kabirajes* fill their purse by self-styled titles, fraudulent advertisements and spurious medicines. I am a friend of our *Aryan Aroedic* system of treatment on scientific principles, and I honor its true votaries, but I hate these *kabi-*

and the public.

First, let us consider the education and lives of these *kabirajes*. Do they really go through any system of education, and do they pass any examination? Surely no. Most of them in their student-life remain in the houses of some respectable *kabirajes*, their pupils and non-pupils. This is the only qualification of a *kabiraj* now. And see from what class these students are recruited. Not generally from the intelligent and successful, but from the dull and unsuccessful students who have failed to shine in other spheres of life, and who wish to get an easy push in this world. The high sounding titles which they put after their names are almost all self-styled, and not acquired by passing any examination.

Secondly, let us consider the nature of their medicines. One of the most fortunate *kabirajes* of Calcutta most extensively uses the allopathic medicines, with *kabirajes* names only. I know the *kabirajes*, who are loudest to decry the use of quinine by their advertisements, describing it as a deadly poison, and the most forward to use it under a disguised *kabiraj* name. These unscrupulous *kabirajes*, who warn the public not to use quinine, the great redeemer of India from malarial poison, in any disease; but who themselves at the same time use it extensively with a false *kabiraj* name, are greatest enemies of our country. The public should know well that, but for quinine, India would have been a great desert. Alas! Our best friend has been described by these selfish *kabirajes* as our worst foe. Now we see how genuine is the nature of their medicines! I know that now it has become a gentlemanly fashion to make money by deceiving the ignorant public by lectures and advertisements. But deception in medicine is surely criminal, or it ought to be so. I ask you, Sir, is there no remedy to put a stop to such fraud on the part of the *kabirajes*?

Yours &c., HARA KALI SEN, C.M.S.

RANIGI, 25th April 1898.

HIGHLY PLACED ANGLO-INDIANS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—Here are a few more names for our record of successful and well-placed Anglo-Indians. My lists are confined to men trained in India:—

1. W. B. Hamilton, Presidency Magistrate, Bombay.
2. S. A. Kyte, Deputy Collector, Poona (Retired List), now Police Commissioner, Baroda State.
3. William Ashby Ingle, Senior Deputy Collector, Sind Commission, Cantonment Magistrate, Quetta, &c., (Retired List), now Municipal Secretary, Sukkur.
4. Arthur Henry Phussett, C.I.E., City Magistrate, Poona, President of the Municipality (just retired.)
5. E. H. Hearn, Superintendent, Deccan Revenue Survey, Poona.
6. William Almon, Assistant Collector, Abkari, Bombay.
7. William Bedford, Chief Superintendent, Accountant General, Bombay.
8. Walter Quambrough, Manager and Director, Agra Bank, London.
9. M. T. Carroll, Manager, Messrs. William Watson and Co., Bombay.

10. John Ballard, Superintendent, Government Printing, Bombay.

11. H. F. Brown, Superintendent of Police, Bombay.
12. Patrick Ryan, Barrister-at-Law, Assistant Secretary, Government, Bombay, Presidency Magistrate, Bombay, &c.
13. Nathaniel Spencer, Judge, Small Cause Court, Bombay.
14. Charles Levett Yeates, Assistant Secretary to Government, Bombay.
15. J. Boyce, Superintending Engineer, Punjab, Government Flotilla, Sukkur.
16. Charles Gilder, (Rev.) Chaplain, Candy's Church and Indo-British School, Bombay.

Yours &c., W. H. T.

KARACHI, 15th April 1898.

(Bombay is publishing a formidable list of "men who have built the Empire." Will other informants add to our store of knowledge?—Ed. I. M. R.)

10.

HOW TO SUCCEED WITH A PHARMACY BUSINESS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—In your last number you published a letter re chemist's shops in India. Perhaps those interested in this line will find the following maxims of great benefit. They are extracted from the *Montreal Pharmaceutical Journal*:—

"If you see a customer enter, turn your back and look at some bottles on the shelf. It has an air of sociability.

Always have the floor of your store mopped up in the busy time of the day. It impresses the customer with the idea that you value cleanliness. The same rule would also apply to your windows.

If a lady asks for a postage-stamp, exclaim, "Don't you see that I am busy?" If the directory is wanted, shout, "Couldn't you see it when you came in?" Perhaps she doesn't feel humble enough already at asking the favor of you, and these little pleasantries will put her in the proper mood.

Distribute two or three cats over the store. It makes fun when a customer brings in a dog.

If a lady asks about perfumes, take an atomiser and spray some in her eyes. When she sees how lavish you are with it she will appreciate its value.

Never put up a prescription in less than half an hour after you receive it. You are the best judge of its urgency.

Never change the contents of your showcase. Customers who have been coming in for several years might miss sight of old friends.

If you are selling tooth-brushes, always rub them across your hand or sleeve to show how pliable the bristles are. It enhances the value to the buyer.

Carry out these rules for six months, then apply for an increase of salary."

Yours, &c., D. O. C.

THE C. D. ACTS IN INDIA.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—In your last issue (15th April) there is a long letter by one who arranges to himself the high-sounding title—"A Hater of Frauds." If he will kindly come out of the gloom in which he has enveloped his identity, I will try to dispel the moral gloom in which he lives. I

suppose the others of created beings with an evil, there are those who will sell light darkness, and darkness light, and whose moral strabismus is so chronic that it becomes past operation:

If he had even read past numbers of the *Record*, he would have been a little less butteques and extravagant.

It is so easy to write oneself down "A Hater of Frauds." I suppose he includes Dr. BLACKWELL's name in the list of frauds. Why, my dear Editor, the whole history of the Government Prostitution Regulations is interwoven with attempts at fraud. From dear old Lord ROBERTS, who had to eat his words when he posed as innocent ignorance before the Commission, to the proved disobeying of orders from 1859 to 1893; and with the present unholy attempt to bring them back by throwing the dust of pious intentions in the eyes of outsiders, and doing away with the name of "Lock" Hospital, substituting for it the vague term "Cantonment," there has been a deal of "fraud" somewhere of which Dr. BLACKWELL has had no share. Has "the Hater of Frauds" had any? Perhaps our Editor might publish Dr. B's. article and let it speak for itself.

Yours &c., WM. HUNTLY, M.A., M.D.
NUSSEERABAD, 26th April 1898.

—:—

BURDENSOME DUTIES AND ILLEGAL ORDERS. TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Perhaps it is as well you should know the following as one of the irregularities going on in the Station Hospital, Deolali. I send you this to comment on and publish if you think proper or not.

Recently an order was issued by the S. M. O. here that "Soldiers admitted into hospital should hand over all valuables belonging to them to the Assistant Surgeon in charge and he was to forward the same to the depôt Adjutant for safe custody." This order arose from the Assistant Surgeon objecting to hold himself responsible for losses, as he was not provided with any means of securing the valuables. On the first occasion arising, the money, &c., was taken over and a trustworthy A. H. corps ward attendant was despatched to the orderly-room to hand over the money, &c., but the authorities there ordered that for the future an Assistant Surgeon was to carry out this work and hitherto it has been done but with a good deal of reluctance, yet none of these Warrant Officers have openly protested against being made to go over each time a patient desired to have his money, &c., put into safe custody. Furthermore when the man was leaving hospital a W. M. O. received it personally from the depôt Sergeant-Major and bringing it to the hospital handed it over to the patient. It is a well known fact that the staff of the hospital is far below that authorised number, and during the trooping season is actually overworked, also in the non-trooping season there is as much work as they are able to get through, and in addition to this to have a duty of such a nature thrown upon them when it could be easily trusted to a ward servant or dooly bhaier, how often do we know of over a thousand rupees being entrusted to these men and very seldom have they failed to do it to the entire satisfaction of their superiors. I leave it to you to treat this subject as you think best.

Yours &c., JUSTICE.

A SUPPOSED LADY DOCTOR.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—The *Baluchistan Gazette* of 8th April 1898 says:—"At her recent examination in Persian by the Lower Standard, Miss STROTTSBURY, L.M.S., (Lady Dufferin Fund) has, we believe, passed well, and we congratulate her accordingly. We take this opportunity of also complimenting Miss STROTTSBURY on the success she has attained in her profession and her increasing popularity in this town. We believe she was the means lately, under Providence, of saving the life of the daughter of our respected townsman, Mr. WASUPAN MUDLIAR, Treasury Head Accountant, who was attacked with that fell disease in Quetta, pneumonia; and we hear nothing but praise of Doctor Miss STROTTSBURY on all sides."

You will be glad to give this a little corner in the *Record*. It does the girl credit for the manner in which she has tackled the Pushto and Persian examinations. And yet they say Anglo-Indians are not worth anything? Have any of the largely paid English lady doctors imported into the country on salaries twice as high as that given to our girls, ever attempted anything of the kind in India, to master the language of the people among whom they are put to work?

Miss STROTTSBURY, it might be mentioned, a few months ago, passed successfully first the lower and then the higher examinations in Pushto. She is probably the first woman who has ever passed in this language.

Yours &c., ANGLO-INDIAN.

—:—

THERAPEUTICS OF PHULWA.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I send this note in reply to Dr. MACLEOD's query in your paper of the 15th April.

Phulwa is a concrete oil expressed from the seeds of the Indian butter tree (*Bassia Butyracea* N. O. Sapotaceae), the tree is called in the Kumaoni language, where it principally grows, *chayard* tree, the fruit exactly resembles loquat. The ripe pericarp is sweet and from its juice a kind of gur is manufactured, from the seed oil is expressed which, on solidifying, looks like tallow and is called *phulwa*.

As an article of diet, it is used by the poorer classes in place of "Taj," oil, and by unscrupulous "ghose" vendors as an adulterant of ghee. Medicinally it is not much used but is highly valued for its physical properties as a lubricant and emollient. In fact it is the hill man's substitute for glycerine or lanoline in the treatment of chapped hands, feet and face—a condition which is so common in winter.

I have used it as a basis for suppositories and soluble bougies, and also mixed with sweet oil, as a basis for various ointments.

I do not think there is much difference between cacao butter and phulwa.

Yours &c., H. D. PANT, L.M.S.,
Assistant Surgeon.

GONDA, 23rd February 1898.

ANGLO-INDIANS AS MISSIONARIES.

TO THE EDITOR, "INDIAN MEDICAL JOURNAL."

SIR,—I do not intend at present to publish the long list of successful Anglo-Indian missionaries of this land, but I desire to have a record made of the work of two missionary women of high repute. Here is what the *Weekly Guardian* says:—

"The Methodist Episcopal Church has honorably interested herself in the spiritual welfare of the Anglo-Indian and country-born European population of this land, and from this community have come forth of her noblest workers, both men and women. Of the latter, one in North India, and one in the South, have been conspicuous for years in successful spiritual work, *i. e.*, Mrs. Barbara Brown, of Lucknow, and Mrs. GRACE STEPHENS, of Madras.

The Christian community at large will be genuinely grieved to hear of the death of the former."

Yours etc., A MEDICAL WOMAN.

THE PLAGUE IN CALCUTTA.

As we go to Press, we have received the official announcement that the Bengal Government has pronounced Plague to be in existence in Calcutta. The announcement was made at noon on the 28th April, and is based upon the bacteriological opinion of Mr. Haffkine, to whom the blood of one of the suspected cases was sent for examination, and which Mr. Haffkine declares contains the specific plague bacillus. This opinion is further supported by the statement of a few official medical officers. Orders have been issued by Government for house-to-house visitation, segregation and inoculation. Up to the present time nine fatal cases are reported. A panic has been caused and a tremendous exodus of natives has commenced.

Book Reviews & Medical Trade Notices.

ELEMENTS OF LATIN FOR STUDENTS OF MEDICINE AND PHARMACY.

By GEORGE D. CROTHERS, A.M., M.D.,

Teacher of Latin and Greek in the St. Joseph (Mo.) High School; formerly Professor of Latin and Greek in the University of Omaha.

and

HIRSH, H. BICE, A.M.,

Instructor in Latin and Greek in the Boys' High School of New York City.

(Publishers: The F. A. DAVIS Co. Philadelphia Pages 28, 242.)

A VERY clear and simple exposition of the use of the Latin language in medicine is contained within the covers of the little volume before us. A vocabulary and general index are appended, and, while grammar and glossaries of medical and anatomical words are included, the art of prescription-writing is fully explained. Altogether the work is an exceedingly handy one, for medical men, it is well known, are not always over careful as regards their treatment of Latin.

PHYSIOLOGY AND PATHOLOGY OF THE GASTRO-INTESTINAL SYSTEM.

By Dr. ROBERT GUNSTURT.

Director and Principal Teaching Surgeon of the Royal Infirmary, Victoria.

Translated with the permission of the Author.

By A. S. LAYTON.

With a Preface by D. J. LAMON, M.D., F.R.C.S. Lond., &c.,
Professor of Pharmacology in the Queen's College and
Victoria University.

(Publishers: JOHN WRIGHT and Co., Bristol. Price 2s.)

This excellent little book, dealing, as it does, with various ethical subjects, will be found of equal value to both physicians and their patients. We recommend to both these classes the careful study of the author's valuable observations of such points as Gossip; Harmful Influence of Persons surrounding the Patient; Corruption of Doctors by the Public; and Medical Aid Societies and their medical officers. Dr. GUNSTURT seems hopeful that when a new generation arises, the evils complained of will shakeless right themselves, but it will of course be a question of time.

Books in our office awaiting review:—

Webster: Diseases of Women.

Waring: Operative Surgery.

Bugler-Smiths: Ovariectomy.

Sauers: Diseases of Women.

Pearse: Relapsing Fever.

Hughes: Malta Fever.

Walter: Practical Psychology.

Macdonald Yearsley: Diseases of Men.

Monson: Cardiac Failure.

Pandian: Indian Village Folk.

Orothers and Bice: Medical Latin.

Chovin: Physical Diagnosis.

Brindley James: Rheumatism.

Gribble and Patrick Hehir: Outlines of Medical Jurisprudence for India.

BEEF-TEA TABLETS.

Messrs. BRAND & Co., of 74, South Lambeth Road, have sent us some samples of "Beef-tea Tablets" for examination. We find that the tablets consist of a well-prepared meat extract containing meat fibre and some wheat flour and dried in the form of cakes. The tablets contain only 5.5 per cent. of moisture, and were found to be free from chemical preservatives, as claimed by the manufacturers. The retail price of each tablet is 2d., and one is stated to be sufficient to make a breakfast cup of "beef-tea."

LACTOPEPTINE.

NOTHING but complete satisfaction can possibly result from the administration of RICHARD'S Lactopeptine which, in regard to its ingredients, is little more or less than a valuable combination of all the best known digestive agents. After a trial of twenty-one years, this up-to-date medicine maintains its place in popular favor in cases of Heartburn, Dyspepsia, Indigestion, Cholera, and wasting diseases. It is pleasant and easy to take, especially in its form of 5 grs. tablets. We can confidently recommend it to the medical profession generally. Order from John M. Richardson, 44, Abchurch Lane, London, E.C. 4, (Lancette Agents), Messrs. Baillière & Co.

GOVERNMENT OF INDIA.

Surgeon-General.—Lieut.-Col. B. B. C. Craythorne, M.B., and Surgeon-Major B. B. C. Craythorne, M.B., to be Surgeon-General, Calcutta, 1st Oct. 1898.

Surgeon-Lieut.—Charles John Mills, Algernon Francis, William Henry Bandy, Francis Hammond Watson, Arthur Gifford, Edgar John Munn, William Carr, John Archibald Hamilton, to be Surgeon-Lieut.

Surgeon-Major.—Surgeon-Lieut. Frank Walling, and Charles Montague Mather to be Surgeon-Major.

Surgeon-Lieut.—Surgeon-Lieut. Samuel Evans and James Thomson to be Surgeon-Lieut.

Surgeon-Lieut.—Col. Sir George King, M.B., I.M.S., retired from the service, 30th Feb. 1898.

Surgeon-Capt.—Gilbert Capel Hall, M.B., I.M.S., retired from the service, 12th March 1898.

The undermentioned medical officers have been permitted to retire from the service.

Surgeon-Lieut.—Col. Sir Alfred Swaine Lathbridge, M.D., I.M.S., 1st April 1898.

Surgeon-Lieut.—Col. James Moorhead, M.D., I.M.S., Civil Surgeon, Bengal, 30th May 1898.

The services of the undermentioned officers are replaced at the disposal of the Govt. of Bengal:—

Surgeon-Major T. Grainger, M.D., M.S.

Surgeon-Capt. E. H. Brown, I.M.S. (Bengal).

Surgeon-Capt. C. E. M. Green, F.R.C.S., I.M.S.

Surgeon-Capt. D. M. Moir, M.B., M.S., I.M.S.

Surgeon-Capt. O. R. Stevens, M.D., F.R.C.S., I.M.S.

The services of Surgeon-Major J. A. Cunningham, M.D., M.S., I.M.S. are replaced at the disposal of the Govt. of the Punjab.

The services of Surgeon-Major R. Pemberton, I.M.S. (Madras), are replaced at the disposal of the Govt. of Madras.

Surgeon-Col. T. H. Hendley, C.B., I.M.S. (Bengal), to be Insp.-Genl. of Civil Hospitals, Bengal, from 9th April 1898.

The services of Surgeon-Major C. M. Thompson, M.B., I.M.S. (Madras), are replaced at the disposal of the Govt. of Madras.

The services of Surgeon-Major Karaji Cursetji Sanjana, I.M.S. (Madras), are replaced at the disposal of the Govt. of Madras.

BENGAL GOVERNMENT.

Surgeon-Capt. R. Bird, B.Sc., Med. Officer, Med. Coll. Hosp. and Offg. Prof. of Physiology, Med. Coll., Calcutta, is allowed, privilege leave for three months, 21st April 1898.

Asst. Surg. Chuni Lal Das, Gaya Pilgrim Hosp., held charge civil station of Gaya from 24th March 1898.

Surgeon-Major J. B. Gibbons, Supdt., Campbell, Med. School, and Hosp., Scaldah leave for three months, from 25th April 1898.

Mr. R. B. Gardiner, Under-Secy. to the Govt. of Bengal, P. W. D., to be Secy. to the Plague Commission, Bengal.

The Lieut.-Govt. is pleased to appoint the following gentlemen to be members of the Plague Commission, Bengal:—
Surgeon-Major R. H. Charles, vice Surgeon-Lieut.-Col. J. Leyland.

Surgeon-Capt. H. W. Pilgrim, vice Surgeon-Major A. W. D. Leaby.

Surgeon-Lieut.-Col. B. D. Murray, Brig.-Surgeon, Col. J. O'Brien.

Surgeon-Lieut. R. F. Wilson made over charge Banohi Jail to Surgeon-Lieut.-Col. F. B. Swaine, 6th April 1898.

Asst. Surg. P. Fitzpatrick, Med. Officer at the Sandheads, privilege leave for one month and 23 days, from 18th April 1897.

Asst. Surg. P. Fitzpatrick, Med. Officer, Sandheads, leave for one day.

Asst. Surg. R. G. C. Mills acted as Med. Officer Sandheads from 30th April to 6th June 1897.

Asst. Surg. R. G. C. Mills did duty Fanny, Genl. Hosp. from 18th to 20th June 1897.

Asst. Surg. John Alexander Dutt made over charge Darbhanga Jail to Surgeon-Capt. C. E. M. Green, 12th April 1898.

Asst. Surg. Alexander Nath made over charge Bhatnagar Jail to Surgeon-Major T. Grainger, 12th April 1898.

Asst. Surg. John Nath made over charge Bhatnagar Jail to Surgeon-Major T. Grainger, 12th April 1898.

Asst. Surg. John Nath made over charge Bhatnagar Jail to Surgeon-Major T. Grainger, 12th April 1898.

Asst. Surg. Chuni Lal Das, Gaya Pilgrim Hosp., held charge civil station of Gaya from 24th March 1898.

PUNJAB GOVERNMENT.

Asst. Surg. Mohd. Baksh to Jullundur, Genl. on special plague duty, from 12th April 1898.

Asst. Surg. Bai Sahib Bhagwan, Genl. on special plague duty, from 12th April 1898.

Hosp. Asst. Ganpat Rai, on special plague duty, from 12th April 1898.

Hosp. Asst. Sher Bah to Mansingh, Genl. on special plague duty, from 12th April 1898.

Asst. Surg. Harmand Das, Genl. on special plague duty, from 12th April 1898.

Hosp. Asst. Govindan Das, on special plague duty, from 12th April 1898.

Hosp. Asst. Abdul Hamid, Genl. on special plague duty, from 12th April 1898.

Hosp. Asst. Mohd. Karim, Genl. on special plague duty, from 12th April 1898.

Hosp. Asst. Umar-ud-din, Genl. on special plague duty, from 12th April 1898.

Hosp. Asst. Gurbaksh Singh, Genl. on special plague duty, from 12th April 1898.

The leave granted to Hosp. Asst. Chaudh. Kadir from 31st Oct. 1897 is extended up to 1st April 1898.

Asst. Surg. Nand Lal Udayan, doing general duty Mayo Hosp., Lahore, was placed on special plague duty at the inspection post at Beas, from 3rd April 1898.

Hosp. Asst. Abbas Ali Shah was placed on general duty at Peshawar, 14th March 1898.

Hosp. Asst. Abbas Ali Shah, doing general duty at Peshawar, four months' leave from 30th March 1898.

Hosp. Asst. Girdhari Lal, doing general duty Mayo Hosp., Lahore, and Lodhiana Pilgrim Hosp. special plague duty Jullundur dist., from 2nd April 1898.

The services of Hosp. Asst. Ganpat Rai being no longer required in the Milly. Dept., he reported his arrival to the Civil Surgeon, Simla, 5th April 1898, for special plague duty.

Hosp. Asst. Asht Khan was placed on special plague duty, Simla, from 2nd April 1898.

CENTRAL PROVINCES GOVERNMENT.

Medical pupil Vithal Baghoba Landay, Banda Branch Disp., Saugor dist., held charge Banda Poor-House, from 4th Sept. to 10th Dec. 1897.

Hosp. Asst. Ujagar Peshad to Chhindwara Poor-house, from 1st Nov. 1897 to 31st Jan. 1898.

Hosp. Asst. Sobharan, Birman Fair, was relieved of his duties there 22nd Jan. 1898.

Hosp. Asst. Khalil-ur-Rahman, Mandla Poor-house, to Dindori Branch Disp.

Hosp. Asst. Inayat Hussain, Dindori Branch Disp., to do duty under Civil Surgeon, Hoshangabad.

Hosp. Asst. Inyat Hussain to the Jail and Police Hosp. Hoshangabad.

Hosp. Asst. Hashmat Ali, Seoni Poor-house, was deputed on special duty Chhapara Cattle Fair.

Hosp. Asst. Hashmat Ali to do duty under Civil Surgeon, Seoni.

Hosp. Asst. Hashmat Ali to do duty under Civil Surgeon, Nagpur.

Hosp. Asst. Ramchandra Sitaram to do plague duty at the Indora Segregation Camp from 6th current.

Hosp. Asst. Hashmat Ali, Hinganghat Branch Disp., to Wundla dist.

Hosp. Asst. Mohan Lal, Hinganghat Branch Disp., three months' privilege leave.

The services of Hosp. Asst. Sayid Hussain are placed at the disposal of the P. W. D. for famine duty, Balaghat dist.

Hosp. Asst. Shonda Lal, Lohaghat Poor-house, Saugor, from 2nd July 1896 to 5th Feb. 1897, and doing duty under Civil Surgeon of Saugor from 9th Feb. to 21st March 1897.

M. S. P. AND OUNCE GOVERNMENT.

Asst. Surg. Mohd. Chaudh. Chaudhary, Baa Bahadur, Thompson Hosp. and Lecturer on Medicine, Med. School, Agre, privilege leave for three months from 4th May 1898.

Asst. Surg. Chetan Singh, Indr. Dwy., Meerut, privilege leave for three months.

Hosp. Asst. Suleman Khan, City Branch Dwy., Meerut, to hold charge Sadr Dwy., Meerut.

Asst. Surg. Bahadur Singh, from plague duty, Hardwar, to that at Saharanpur Ry. Stn.

Asst. Surg. Bankim Chandra Nayak, from plague duty, Hardwar, to that at Ghazabad Ry. Stn.

Asst. Surg. Chaman Singh, from plague duty, Saharanpur, to that at Hardwar.

Asst. Surg. Hari Ram, from plague duty, Ghazabad, to that at Hardwar.

Asst. Surg. Baldeo Singh to do plague duty at Bareilly, from 15th March 1898.

Asst. Surg. Ghulam Mustafa, from plague duty, Aligarh, to that at Hardwar, Saharanpur dist.

SUBMA GOVERNMENT.

Hosp. Asst. H. C. Bannerjee assumed charge Civil Hosp., Ma-ulha, Thongwa dist., 27th March 1898.

Hosp. Asst. H. C. Bannerjee assumed charge Jail Hosp., Ma-ulha, 27th March 1898.

Hosp. Asst. Karim Khan assumed charge of a portion of the Pynatan section, 22nd March 1898.

Hosp. Asst. Syed Nur Ali assumed charge of a portion of the Pynatan section, 24th March 1898.

Hosp. Asst. Peter Aquah assumed charge Civil Dwy., Pynatan, Pegu dist., 25th March 1898.

Hosp. Asst. G. C. Chackraborty assumed charge of duties with the F. W. Dept., Pegu div., 26th March 1898.

Hosp. Asst. Krishna Gir assumed charge Lock-up, Kyaukse, 16th Feb. 1898.

Hosp. Asst. F. A. Jeyela Rao assumed charge Police Hosp., Bhamo, 15th Feb. 1898.

Hosp. Asst. Abdul Khader, six months' leave from 7th March 1898.

Hosp. Asst. F. A. Jeyela Rao assumed charge of his duties with the Reinforcing Party, Military Police, at Bhamo, 26th Feb. 1898.

Hosp. Asst. Bishan Lal assumed charge Police Hosp., Sadon, Myitkyina dist., 18th March 1898.

Hosp. Asst. Bishan Lal assumed charge Civil Hosp., Sadon, Myitkyina dist., 18th March 1898.

Hosp. Asst. Behari Lal assumed charge Central Jail, Rangoon, 2nd April 1898.

Hosp. Asst. Jeet Singh assumed charge Police Hosp., Myitkyina, 24th March 1898.

Hosp. Asst. Rattan Chand assumed charge Outpost Hosp., Namkhan, Bhamo dist., 29th March 1898.

G. O. C. O.

Hosp. Asst. Muhammad Kasim qualified himself for promotion to the next higher grade, 1st Oct. 1897, and is entitled to the pay of the same.

Hosp. Asst. Rustam Ali and Dare Khan qualified themselves for promotion to the next higher grade, 16th April 1897, and are entitled to the pay of the same.

Med. student M. Kuppaswami Pillai has been admitted into the service as Sub-Hosp. Asst. from 17th July 1897.

ASSAM GOVERNMENT.

Babu Brajendra Mohan Goswami, a passed student of the Temple Med. School at Patna, is apptd. a Civil Hosp. Asst. in Assam and posted to Guahati for duty as a supy., from 2nd April 1898.

Privilege leave of absence for one month is granted to Hosp. Asst. Durga Gati De, in med. charge Koklamukh cooile depot, Sibesar dist., from 2nd April 1898.

Hosp. Asst. Mahamad Tahir, a supy. Nowgong dist., to Sibesar dist. to Koklamukh cooile depot, from 2nd April 1898.

Privilege leave of absence for three months is granted to Hosp. Asst. Amir Uddin Ahmed, Dair Dwy., Garo Hills dist., from 7th April 1898.

Hosp. Asst. Kamal Charan Pal, a supy., Garo Hills dist., to Dair Dwy. in that dist., from 7th April 1898.

Hosp. Asst. Inder Chandra Karmakar, having passed the Sept. Prof. Exam. of Hosp. Assts., is promoted to the 3rd grade from 2nd Jan. 1898.

NOTICES TO CORRESPONDENTS.

The charge for inserting a Domestic Occurrence is Rs. 1 for subscribers and Rs. 2 for non-subscribers, which should be forwarded in stamps with the announcement.

BIRTH.

HODGSON.—On the 13th April, at Khandala, the wife of Surgn.-Capt. C. O'C. Hodgson, A. M. S., of a daughter.

MARRIAGES.

ROUSE-STEWART.—On the 13th April 1898, at the Church of the Epiphany, Outack, by the Rev. Cyril Price, Francis James Rouse, Assistant Engineer S. N. Railway, to Edith Mabel, third daughter of Surgn.-Major W. D. Stewart, I. M. S.

THOMAS-COOK.—On 2nd April, at St. Stephen's Church, Ootacamund, by the Rev. C. H. Malden, Chaplain of Ootacamund, Captain F. H. S. Thomas, I. C. S., to Diana (Daisy), third daughter of Surgn.-Lieut.-Col. H. D. Cook, I. M. S.

MCCARTHY-COOK.—On 2nd April, at St. Stephen's Church, Ootacamund, by the Rev. C. H. Pelly, Bishop's Chaplain, assisted by the Rev. C. H. Malden, C. D. McCarthy, Indian Forest Service, to Annie Frances Tytler (Fanny), second daughter of Surgn.-Lieut.-Col. H. D. Cook, I. M. S.

HIGMAN-BARON.—On Wednesday, the 15th April, at Abu Road, by the Rev. L. F. Phillips, M.A., Chaplain of Muttra, Walter Henry Higman, Assistant to Traffic Supdt., B. B. and C. I., Railway, to Mildred Lucy second daughter of Thomas Baron, Civil Surgeon (Retired).

DEATHS.

BUSH.—On the 10th of April, Easter Sunday, Catherine, the wife of J. Graham Bush, of Moontal Estate, Assam, and daughter of the late Surgn.-Col. Hilson, C.I.E., I. M. S., aged 36 years.

FRASER.—At Burki Station Hospital, on the night of the 13th April 1898, of Bright's disease, Evangeline (Eva) the dearly beloved wife of 1st class Asst. Surgn. Edwin Walter Fraser, I. M. S. and the youngest and last surviving daughter of the late Asthetus Sparrows Esqr., aged 37 years 6 months and 8 days. Deeply and sincerely mourned by her sorrowing husband, children and relatives.

KILLOWAY.—On Monday, 4th April, at Dinapore, Victoria, Eileen, infant daughter of Assistant Surgeon S. Killoway.

NOTICES TO CORRESPONDENTS.

J. C. B. writes:—"With reference to your letter in the *Indian Medical Record*, dated 1st April 1898, in re to the [improvement of our department, I regret to see one of the chief points have been omitted. The words 3 years in the grade should be abolished, as the enhanced rate of pension of Rs. 200 and Rs. 250 now asked for will be attained by very few (if any), if the rule or this condition is allowed to exist, for by the time several of our hands approach the senior grade the age clause will affect them. I am sure there has been an oversight and I hope you will please endeavour to rectify it and oblige."

F. D. (Kamptee).—You will find all the information you need concerning medical education and medical qualifications in the new edition of the "Medical Register and Directory of the Indian Empire."

CLIMATE AND SOIL AREA

Marshes may, of course, be permanent or temporary, and in the latter the flora need not be distinctive; but if the condition is prolonged, healthy vegetation will not thrive, and gradually the flora must change.

Now all these marshy conditions, temporary or permanent, affect and alter the neighbouring atmosphere or local climate.

The practical difference between the atmosphere of drained land and marshy land is illustrated in the following passage from the evidence given by Mr. BAILEY before the Metropolitan Sanitary Commission, talking of Stirlingshire and Perthshire he said:—"Few cases of ague now occur, in the undrained condition of these districts they were subject to dense fogs, especially in the autumn when much rain had fallen, but since the general introduction of drainage these fogs are seldom seen."

In other words when the sub-soil water is sufficiently high to be subject to the direct force of evaporation, large quantities of moisture are given off, which at night settle down in the form of a cold, damp fall.

I have now shown that when man by his operations on the soil has driven away malaria, or when he has induced it, he has at the same time brought about a coincident change in the local climate.

The influence of trees remains to be considered

Trees.

There are many curious and amusing things to be met with in the literature of malaria, and the portions that deal with the influence of trees are not exceptional in this respect.

It may be worth while to recall some of the ideas that have been expressed, as evidence of the confusion of mind, the "anarchy of thought" to use a phrase of Dr. QUAIN'S which characterised our predecessors' attitude to these protean forms of disease.

It does not surprise us to find a considerable divergence of opinions on the subject, for this is the characteristic feature of every side of the malarial question, in this case we have a divergence amounting to a direct contradiction.

Some people would cut down trees to remove malaria, some would plant them for the same purpose.

Some hold that trees neutralised the poison, others that the poison was particularly virulent close to trees, everything was topsy turvey, JULIA DE FONTENELLE,⁸ CHARGEX,⁹ LEWIS,¹⁰ and SPRENGER,¹¹ maintained that some subtle chemical change took place, caused either by the trees absorbing the poison, or exhaling some principle which neutralised it.

Another and larger set of writers hold that trees were merely passive agents and acted as a screen or filter, so as to obstruct the passage of the miasm. How often do we read of that magic barrier or belt of trees? JOHNSON,¹² MACCULLOCH,¹³ WILLIAMS,¹⁴ DRAKE,¹⁵ MONTFALCON,¹⁶ ARNHEIM,¹⁷ DUNN,¹⁸ supported this view.

FRAGUSON¹⁹ tells us that trees have a special attraction for the poison, that it adhered to lofty, umbrageous trees. "This is so much the case," he says, "that it can scarcely be separated from them, it is wonderful to see how close to the most pestiferous marshes they will venture provided they have an intervening belt of trees."

BLAIR,²⁰ and MOREHEAD²¹ believed that the proximity of trees was dangerous, the former says that the poison

accumulates under trees, the latter that it is attracted by the foliage of trees, and that the miasm is derived from them, and between them and the ground.

While LA ROCHE²² talks of it being entangled in jungle and brushwood and that when this is cut down, the workmen who stand up are not affected, while those who sit or lie down are.

Such ideas are not likely to appeal, in their entirety, to the present day reader, but I may well ask what have we got to put in their place? What clearer light has been thrown upon the subject?

Some one may reply—why, we have got the Eucalyptus Globulus of course!

Well, I have not forgotten the Eucalyptus Globulus or the Eucalyptus Rostrata, and it is impossible to do so, it is the standing dish of every modern writer who touches on the subject, it is the sole source of comfort they can find, on all possible and impossible occasions it is dragged in, it is the universe panacea, and if some of these writers had their way, the whole world would soon be covered with it.

This extensive vogue originated in the observation made by some ingenious individuals, that in Australia there was no malaria, but there was plenty of eucalyptus, while in other parts of the world there was plenty of malaria, but no eucalyptus, from this the idea was quickly taken up that the eucalyptus must possess some valuable property which was antagonistic to the development of malaria.

The fact that the climate of Australia is suitable to the eucalyptus and unsuitable to malaria, and that this is the cause of the presence of the former and the absence of the latter is much too simple for up-to-date science; something more abstruse is looked for.

Accordingly the Italian and French Government took up the matter on a large scale, and extensive experiments in eucalyptus planting were set on foot in Italy, Algiers and other places.

While it appears that a certain measure of success has been achieved, there have also been some failures and disappointments.

The tree is not suited to all climates, and in Algiers whole plantations, upon which large sums of money were expended, after a few years, promising growth have succumbed to the rigors of an exceptional winter.

This is a point of the greatest importance, where the planting of eucalyptus trees is meditated, and from this point of view a very unfavorable opinion of the eucalyptus was expressed by THOMAS-GODFREY in 1855. It is to be noted however that LATREILLE, in his recently published work "Trait du Paludisme" speaks highly in its favor.

The eucalyptus appears to possess the very valuable property, it is a quick growing tree and a great absorber of moisture, as the so-called miasm is to this latter property that its beneficial action is attributed; it is simply looked upon as another means of draining the soil.

The idea that it has any specific action, I believe, is not accepted.

In all these discussions on the eucalyptus there are two very important things overlooked. One is that the eucalyptus engenders a miasm which is itself malarial, also

gives some idea of the faculty of destroying the soil; the other, that the soil would do as well, always provided it was suited to the climate and soil.

The treatment of malaria is not very rich in this subject at present, which is to be regretted; there are however a few well authenticated observations which are sufficient for my purpose.

First of all let us consider the country in the neighbourhood of Rome which has been more written about in connection with malaria than any other part of the world.

On the authority of many ancient writers, we know that malarial fevers were always present and that marshes prevailed extensively.

The populous and flourishing state of the country in the early Roman days is a sufficient proof, if one were needed, that malarial fevers were then in extent and severity insignificant.

At the first census of *NAVIUM TELLUS* the city of Rome numbered 80,000 citizens capable of bearing arms.

In the days of the *Volscians* there were twenty-three towns and villages in the Pontine marshes, amongst these were Ardea, Lavinium, and Antium, the last, *STRABO* says, was a pleasure resort of the *Cæsars* and *Patricians*.

More significant still is what the same author tells us of *Ravenna*. "A town more surrounded by marshes than any other, yet so healthy on account of being encircled by woods, that it was selected as the best place to train the gladiators." "Mirabile igitur, hoc locus iste habet, quod in palude, aer est innoxius" he says, expressing his surprise that the air of such a marshy place could be healthy.

An important change has come over this district, in the old days it was freely wooded, at present it is almost bare, and to this absence of trees must chiefly be attributed its present feverish state.

True a certain amount of responsibility must be borne by neglected drainage, but as it is evident that in spite of all the care bestowed in drainage in olden days, marshes always existed and existed extensively, it follows that some other and more important factor must be found to account for the different degrees of unhealthiness.

There is no lack of evidence to show, both that the *Agro Romano* was well wooded, and that the people were fully alive to the beneficial action exerted by trees.

A special set of laws, (The Law of the Twelve Tables) was directed towards the preservation of wood.

According to *THEOPHRASTUS* the plains of Latium were covered, and especially towards the sea, by forests of laurel and myrtle of such a size as to be used in ship building.

LANCINI,¹ mentions that in former times there existed on the South side of Rome a thick forest. It extended from *Franetti* and *Albano* to the *Tiber*. He believed in the healthy property of trees.

STRABO, as I have mentioned gave them the credit for the healthy state of *Ravenna*, and curiously enough in 1667 we find *DODDUS* "advocating the measures that have been adopted in recent years, viz., the planting of trees."

The successful result of the planting of the *Eucalyptus* at *San Remo* in the eighties is the corollary of all this.

The ancient woods protected the country from the worst ravages of malaria; they were destroyed wantonly by the hand of man, with the fatal results known to all, and now at this late hour trees have been again planted and the malaria has diminished in their neighbourhood.

The *eucalyptus* has served the purpose, but other trees would have been equally successful.

In no part of the world has the removal of trees been conducted on such an extensive scale as in the United States and Canada, and the invariable result has been malarial fevers.

"It is a well-known fact," *RYAN*² says, "that intermittent and bilious fevers have increased in Pennsylvania in proportion as the country has been cleared of its woods in many parts of the States." *LEWIS*³ for California and *STANTON* for Canada have the same story to relate, as immigration spread further west and the forests were cleared, malarial fevers regularly broke out.

I may mention one or two instances related by *ARMAND*,⁴ "The town of *Blidah* was at one time embedded in extensive orange groves, which made it a delicious oasis at the foot of the *Atlas Mountains*, its salubrity was so celebrated that it became a favorite resort of the ancient *Deys* of *Algiers*."

An earthquake in 1825 destroyed a part of it, and in 1830 war wrought havoc amongst its buildings and orange groves, which it took twenty years to repair, during these years it became unhealthy, but when restored to its former state, healthiness returned."

"In the province of *Oran*, a league from the salt marsh of *Misserghin* says *M. SOUSSEYER* (*Mém de Méd Militaire*), was the ancient pleasure resort of the *Deys*, the abundance and purity of the water, the shade of its venerable olive trees made a sojourn there as agreeable as rare in the province of *Oran*, so dry and barren; but the trees have been cut down, there is no longer the same shelter from the burning sun and the camp at *Misserghin* now pays its annual contribution to the endemo-epidemic fever of the hot season." The healthy properties of trees and sheets of water is summarised in the following observation of *FLEURIAN DE BELLEVUE*, that in France and Italy when marshes are well furnished with water and covered with trees planted very close to one another on the banks and causeways, so as to shelter them from the action of the sun, they are as innocuous during summer as the best soil well dried.

Again, we read that in North Carolina, when malaria is very general, "the families that live on the "Dismal Swamp" employed in making shingles, without a patch of clear or dry ground, "enjoy better health than the people who live on their new plantations near the river or swamps; their immunity is attributed to the dense forest in this region." (*WILLIAMSON, History of North Carolina*).

The evidence is, I think, sufficient to prove conclusively the inestimable value of trees in the prevention of malaria, but until their *modus operandi* is clearly understood, it is impossible for any real advance to be made.

In studying malarial phenomena it is always necessary to bear in mind, the general division of continental climates into tropical, sub-tropical, and temperate; and to

distinguish clearly between them. It will be found that the same rules will not apply to temperate and tropical climates; and many errors and much misapprehension have arisen by supposing they would. As for countries which lie intermediate, and which are said to have sub-tropical climates, as Algiers, it is evident that an allowance must be made for the fact that the climates vary from place to place, the temperate preponderating in one district and the tropical in another.

Without further enlarging on this subject I may draw attention to the fact that the instances I have given regarding the action of trees have all been taken from temperate or sub-tropical climates, and I may say that in such climates the influence of trees upon malaria is universally acknowledged.

There are many good reasons for believing that this influence is altogether a climatic one.

The truth at this point may appear to some to become somewhat obscure, if so, it must be attributed to the small amount of attention that has been paid to the subject. As the writer in the *Encyclopedia Britannica* says: "Little comparatively has been done anywhere in the examination of the great practical question of the influence of forests on climate, by means of carefully devised observations."

Such being the case, there is still much to be learnt, and anything I may say must be regarded rather as tentative, than final.

It is clear that forests help to make climates more equable. We have seen that "the two chief causes which tend to counteract the effects of terrestrial radiation are forests and sheets of water," "hence the conserving action of forests on climate making the nights warmer and the days cooler, imparting in short to the climates of districts clad with trees, something of the character of insular climates." (*Encyclopedia Brit.*)

Where there are trees the effects of nocturnal radiation are not so intense, because, "the effects of radiation are not confined to a strata of air a few inches thick, but are distributed through a strata equalling in thickness the height of the trees."

The healthiest situation for a house is on the side of a hill, with trees above it, trees on the slope above the house fulfil an important function, they check and break up the currents of cold heavy air produced by nocturnal radiation, which would otherwise flow directly down upon and surround the house; protected by the trees the air about the house is warmer at night, and not subject to sudden chill at sunset.

It is easy to understand that the much vaunted barrier of trees which is supposed to obstruct the passage of malaria, must act in this manner, if in addition the trees possess any other power. It remains to be demonstrated.

The following table of some thermometric observations I made at Darjeeling illustrates these points: (1) the influence of trees on temperature, (2) that two places within 80 yards of each other may have different climates; (3) some peculiarities about the temperature in ravines to which I will refer at another time.

The observations were made with maximum and minimum thermometers kindly lent me by the Meteorological Reporter to the Government of India, the thermometers were placed in open work boxes facing the sun, and raised nine inches above the ground; it was my object to submit them as much as possible to the same conditions that would affect a man lying on the ground.

In most meteorological observations every care is taken to avoid the influence of solar and terrestrial radiation, and every precaution is taken for this purpose. This system, however essential it may be to obtain for true comparative records of air temperature, is unfortunate for the elucidation of the question of the influence of climate upon health, for the thermometers are carefully shielded from the very effects most likely to cause disease, and most frequently associated with malaria.

For the observations two knolls were selected at the same elevation of 7,600 feet and eighty yards apart, one was bare, the other was fairly thickly wooded. The third thermometer station was at the mouth of a small ravine 800 feet below.

It is interesting to observe that in twenty-seven observations the mean daily range under the trees was only

1917, while over the open ground it was as much as 85° F.

The minimum under the tree was of course much lower, and the minimum higher, both is of course only what everyone would expect.

The one climate was very much more equable than the other and presumably much more healthy.

THE NECESSITY FOR SPECIAL EDUCATION IN TROPICAL MEDICINE.*

BY PATRICK MANSON, LL.D., M.D. Aberd., F.R.C.P. Lond.,
Lecturer on Tropical Diseases at St. George's Hospital.

GENTLEMEN,—I have been asked by the authorities of this school to speak a word of welcome to those of you who to-day commence your systematic medical studies. I congratulate you on two things—one, your choice of medicine for your profession; the other your choice of St. George's for a school. Though the medical profession is by no means a bed of roses, perhaps more than any other, it is one which to him who follows it in the proper spirit is full of good things. It is intensely interesting; it is a recreation as well as a study; its influence on society is rapidly increasing; it is a fairly satisfactory means of getting a livelihood; and, above all, it is full of boundless opportunities for doing good. What reasonable man could wish for more? As regards your school, apart from its associations with the past—associations such as few can boast—I can confidently claim that of all the metropolitan medical schools none have shown of late years more energy, greater determination to keep with the times, or more far-sighted enterprise. Nor have the students been unworthy of their school, for St. George's men are known all over the English-speaking world as accomplished physicians and surgeons. More than this, and in a greater measure owing to the high tone of the school and of its social life, which has been carefully cherished by the teachers, they are known as good citizens, brave soldiers, loyal and devoted public servants, and, even better than that, as gentlemen.

* Being a lecture delivered at St. George's Hospital at the opening of the Winter Session, October 1st, 1901, and reproduced from the *Lancet* by request.

You come therefore to an *alma mater* of honorable repute; it must be your care to maintain and, if possible, to add to this reputation. In congratulating you on your choice of a school I do so on the strength of what, since I had the honor of being connected in a humble way with St. George's, I have observed here for myself. I have been especially struck with the energy I have already referred to and that foresight in the management. In every department I find these. Naturally the institution of a lectureship on tropical medicine has appeared to me more especially; but this, I see, only one evidence of the spirit that runs through the entire management. Laboratories, museum, teaching appliances, and teaching are all of the best and most advanced description; and I am especially pleased to remark that the students, so far as my opportunities have enabled me to judge, are not slow to avail themselves of their exceptional opportunities. The mere fact of my being asked to address you on this occasion, I believe, is but another evidence of the desire of the authorities to advance, to extend, and to improve the training they offer. They seem to be impressed with the desirability of something being done for one of the neglected departments of medical education, for tropical medicine, and as they know the interest I take in this subject, I have an idea that this is the reason why I have been asked to come here to-day. I fancy I am expected to ventilate the matter. This being so, the first remark I would make is, that the systematic teaching of tropical medicine, ere many years are over, will be universal in our medical schools. Those who can read the signs of the times and who are best able to judge, regard this as inevitable. Why? Because our country is the centre of a great and growing tropical empire; and, second, because tropical disease in many respects is widely different from the diseases of temperate climates, which, practically, are the only diseases about which at present the student receives instruction. There are dozens of diseases more or less special to the tropics—diseases which demand special knowledge for their diagnosis and successful treatment. Rather over a fifth part of the medical graduates of Great Britain and Ireland practise in warm climates or, being in the army or navy, may be called upon at any time to do so. Surely if tropical practice is so different from practice here, it is highly desirable that this vast army of medical men should be properly equipped for their special work. It may be said, and has been said, that as the principles of pathology and therapeutics are the same the world over they apply in India as well as in England. Quite true. But we have not to do merely with the principles of pathology and therapeutics. As a practical profession we are more concerned with their application which is quite another matter. Similar objections might be, and formerly often were, raised about giving special instructions in such branches as eye disease, skin disease, and so forth, but the advance of our art and the requirements of the public have long ago swept aside these objections. So it is now with the teachings of tropical medicine as a special subject, and so in the near future it will be. A principal reason why hitherto there has been so little done in this matter is this. Candidates for medical degrees know very well that they will not be asked any questions about tropical disease by their examiners, and

so they have not demanded instruction on this subject. And the reason why questions are rarely put on tropical medicine is that the leaders of the profession, those who man our hospitals, who fill the teaching chairs, who examine for degrees, who grant licences to practise, who make the regulations for the education of the youth of the profession, are, in almost every instance, men who have never practised in warm countries, and who themselves have never felt the necessity for a wider and more practical knowledge of the diseases peculiar to these climates. Not having themselves felt the want, they have been slow to acknowledge that such a want exists, and slower still to apply the remedy. But ask those who are best qualified to express an opinion on this subject. Ask the medical men who have themselves felt the responsibilities of practice in the tropics, and more especially those of them who have endeavoured to follow recent developments in tropical pathology. Ask them if they do not think that the medical man who goes out to battle with tropical diseases should have some special instruction and training for the very special and responsible work he has before him, and if they do not think that the medical authorities should take care that the men who do so go out to practise should be properly qualified so far as teaching can qualify. I am sure of their answer. Unfortunately, most of the men of tropical experience live and practise away from the great medical centres. They are hardly represented on the medical teaching, graduating, or legislating bodies, and so it comes that their opinions do not make themselves felt, and that a much needed reform is delayed. It is more especially of recent years, partly in consequence of the enormous expansion of our empire and partly in consequence of the advances in tropical pathology which have signalised the last two decades, that the claims of tropical medicine have become urgent. Formerly the little that was known about tropical disease could be carried in a waistcoat pocket. But of late years so great has been the advance that now-a-days the subject is quite as extensive and quite as special, so as to speak, as ophthalmology, dermatology, gynecology, or as any of those departments of medicine which claim and receive special teaching. More so. When the practitioner in this country is puzzled about a case it is an easy matter for him to call in some one known to be familiar with the class of case he is in trouble about. But in the wilds of Africa, in the islands of the Pacific, in lonely stations in India or China there is no consultant to fall back upon. The practitioner there has himself alone to depend upon. And woe to his patient and, if he has a conscience, to his future peace of mind if he is not up-to-date in his knowledge.

The course of instruction in general medicine usually received in this country is utterly inadequate to qualify for tropical practice. I say so emphatically, basing my assertion on my own experience, my own mistakes, and what I have seen and still daily see of the mistakes of others. Let me illustrate this by a few examples. Take that great scourge of mankind, greater, perhaps, than tubercle itself—namely, malaria. This is eminently a tropical disease. Every day the tropical practitioner is fighting it. Yet what does the student and future tropical practitioner actually know about

malaria when he is stamped as qualified to practice his profession even in the haunts of this disease? He may possibly recognise a tertian or a quartan ague, and he may know that quinine will cure them. Ten chances to one his malarial patients know all that quite as well as he does himself. But could he, any more than his patients, tell a malarial remittent from an enteric fever; could he diagnose a pernicious malarial attack from cholera, it may be, from thermic fever, from apoplexy? He has heard of the malaria germ, but has he seen it; could he recognise it; has he been taught to find it for himself; to make use of the fact of its presence or absence in the circulation as an infallible means of diagnosis? What would an examiner now-a-days do with a student who could not recognise and demonstrate the tubercle bacillus? He would pluck him. At all events, were I an examiner I would pluck him. And if I were an examiner and found that a student, intending by-and-by to practise in the tropics, could not recognise and demonstrate the malaria parasite I would do the same. For I know that the malaria parasite is just as important to him and his prospective patients as the tubercle bacillus is, and that the ability to recognise and demonstrate it is just as necessary for the tropical practitioner. In those terrible sudden forms of malaria which now and again will be sprung on him perhaps the only reliable means of diagnosis lies in ability to recognise the malaria parasite. Life hangs on it. Dr. ANDREW DAVIDSON, whose experience in tropical medicine has been very great, and whose judgment and knowledge are on a par with his experience, on my telling him I was to speak about these things to-day, and sympathising with my views, at my request sent me some memoranda on the subject. He relates a case which well exemplifies the necessity for knowing something about malarial disease before attempting to treat it. He writes: "I had not landed many weeks in Madagascar when I was called upon to see a patient who, I was told, had been suddenly seized with what was looked upon as an apoplectic fit. This was in the afternoon and when I saw him about an hour afterwards, he was lying unconscious, the body in a state of complete resolution. The skin was cool, the pulse and respiration were slow, and there was no stertor. His condition suggested cerebral hæmorrhage or thrombosis. It was, indeed, in a certain sense a case of thrombosis, for, as it turned out, the patient was suffering from the apoplectic form of pernicious malarial seizure, in which, as we now know, certain capillary areas in the brain are permanently or temporarily blocked by malarial parasites and pigment. The disease is by no means a rare one in malarious countries. It had long before been described by TORTI. I had read in GRAVES' lectures of the soporose or comatose seizure, in which fever is a prominent symptom. Here there was no fever, and the possibility that it was a malarial attack never entered my mind. What the precise brain lesion might be I could not decide. But something had to be done, and I saw nothing better than to place a drop of oron oil on the tongue, apply a blister to the nape of the neck, and warn the relations to prepare for the worst. I was gratified to hear next morning that, after remaining ten hours insensible, the patient had recovered consciousness; but what surprised

me most was that there was no paralysis. The patient's chief complaint, in fact, was the blister. In the afternoon of the same day the patient was seized with shivering, fever, and sweating. There could now be no difficulty either as to diagnosis or treatment. The patient probably owed his life to the fact that the apopleptic seizure did not recur and prove fatal, as it often does when treated on the lines I had followed. What I conclude from this is that grave mistakes would often be obviated by special instruction in tropical medicine." Dr. Davidson remarks: "Experience, no doubt, is a good teacher, only the fees are very heavy." The microscope would probably have diagnosed this case correctly, but then one must be taught how to apply it.

I could relate from my own experience many similar stories illustrative of the danger to life with which a working experience in malaria has been bought. As with malaria, so with many less important, though nevertheless very important, tropical diseases. What, I would ask, does the student learn of practical value about beri-beri, a disease which, if he is to practise in the tropics, he is almost sure to encounter often enough, although he may not recognise it when he does come across it? Beri-beri is a very important malady. Occurring both endemically and epidemically, it annually kills its thousands and tens of thousands. It makes the settlement of many fertile lands almost impossible. It kills off the planters' coolies like flies and makes his plantations unprofitable. It fills the hospitals and is a downright scourge in some of the fairest lands of the earth. But it is a disease which can to a great extent be prevented; and it is a disease which can by proper management be robbed of much of its danger. Its recognition, therefore, is of the first importance. Many times, in beri-beri perhaps more than in most diseases, early and correct diagnosis means the saving of life. When I first went to the East, all I knew about beri-beri was its name. This I had sometimes seen in books. I had wondered at its quaintness; perhaps medical student-like. I had waxed facetious about it and had punned upon it. So little did I know about beri-beri that I believed some medical writers who said that it was a kind of anaemia. Examiners, I was told, were not likely to ask any troublesome questions about the symptoms, pathology or treatment, so I skipped the chapter on beri-beri in "Aitken's Practice of Medicine" as being for my immediate purpose useless. Students then, as I suppose students now, worked to pass their examinations as their primary object; to learn their profession was altogether a secondary affair. Little wonder, therefore, I failed to recognise the disease when I first came across it. I well recollect my first case, and the horror and the shame with which it filled me, and still fills me. I was then in practice in Formosa. One day I was called to see a Chinese clerk employed in a European firm. I had known him well as an active, obliging young fellow. I found the patient sitting propped up in a chair, short of breath, dropsical from head to foot, with a cardiac bruit, irregular, tumbling action of the heart, and complaining of a feeling of distress in his chest. As there was no albumin in the urine, and as there was a loud bruit with manifest disturbance of the heart, I felt convinced it was a case of heart disease, and from other circumstances in the case one which treatment

would benefit. I prescribed and gave directions, and went away feeling, and probably expressing by my manner, that we Europeans knew a great deal more about disease than the old Chinese doctor who hitherto, with the assistance of the village idol, had been treating the patient. Next day I went to see the lad expecting to find an improvement. I thought, as I passed the door, that there was a strange hush about the house. I entered what was my patient's room. On the bed, covered with a blanket, there was something long and rounded and still which explained the hush I had noticed; and as I left the house sadder, wiser, and, I trust, humbler than I did the day before. Some years later, being then in general practice at Amoy and in charge of a large native hospital, I used to see a number of Chinese soldiers who came to hospital suffering from what appeared to me, in my ignorance, to be locomotor ataxia. Some could hardly walk, others could just stagger into the out-patient room, and some had to be carried in. The significance of the knee-jerk symptom in spinal disease was then a new discovery and in those days was regarded as a sure sign of locomotor ataxia. In all of these soldiers the knee-jerk was absent, and all of them exhibited what I took to be ataxic symptoms. If you would criticise my diagnostic acumen please bear in mind that in those days peripheral neuritis had not been invented. However that may be, I diagnosed these cases as locomotor ataxia, prognosticated that they would never recover, declared that there was no immediate danger to life, put them to bed, and prescribed strychnine in various forms. But by-and-by, in utter disregard of my prognosis and of my reputation, in the course of a month or two, some of those soldiers whom I had regarded and pronounced as hopeless cripples were walking about; some had even returned to their military duties. This is the pleasant, not to say the funny, side of my mistake. There is another side however—one not quite so funny. A good many of these patients died—died suddenly, just as my dropsical Formosa patient had done. I was mortified as well as puzzled. What was the nature of these cases? My books did not help me. I noticed that whereas some of these paralytic patients were wasted to shadows, others were swollen and oedematous. I also noticed that in most of them the muscles, especially the calf muscles, were tender. Occurring as this disease did as an epidemic, and confined to a very limited area (for most of the cases came from a damp, ill-constructed fort, the casemates of which served as a barrack), and knowing that the Chinese are very fond of pork, I thought that the muscle tenderness and the oedema might be symptomatic of trichinosis. I thought I might be dealing with an epidemic of trichinosis. Indeed, I went the length of searching the muscle for trichinae. If they can help it, the Chinese will not allow their dead to be dissected. I always entertained a great respect for what we in our civilised pride call "native prejudices;" but in this instance, in view of the importance of correct diagnosis, I thought I would run the risk of offending those for once. So with the aid of an old and seasoned native porter I smuggled one of the dead bodies into a piece of waste ground near the hospital, and there behind a wall excised a piece of muscle. Needless to say I found no trichinae. In this way I groped about for a long time in

error of a diagnosis. It was not till months had elapsed and not a few deaths had occurred that I recognised that I had to deal with an epidemic of beri-beri, and it was only then that it began to dawn on me that the poor dropical fellow who had died in Formosa some years before, had really died from beri-beri and not from heart disease after all.

For exactly the same reason—lack of proper teaching—the history of my education in the matter of beri-beri is that of most of the medical men of my generation who in lonely places in the tropics, essayed to practise their profession. And I am grieved to say that in this matter, even at the present day, it is just as it was thirty years ago. My education in beri-beri was got by experience: the young medical man of the present day has to learn in exactly the same costly way as I did and in the same stern school of experience. As Dr. ANDREW DAVIDSON says in his letter to me:—"The fees are heavy." Only the other day I got to know that there had been no improvement on the teaching of beri-beri in all these thirty years. This is how I came to realise the ugly fact. Beri-beri is very common, you may be astonished to hear, in the port of London, especially among the lascars and seedy boys who in many instances form the bulk of the crews of the large steamers trading to the East. The cases are often brought to the Seamen's Hospital. They come on written medical recommendation and are sent as cases of heart disease, kidney disease, almost anything but beri-beri. They are very rarely correctly diagnosed. Now the ship-surgeons who make out the certificates are usually men fresh from the schools and from their examinations, and therefore, presumably, well up in all that is newest in medicine. Here is a verbatim enumeration of some of their diagnoses: anasarca, rheumatism, pericarditis and fits, dyspnoea, cardiac disease, debility, asthma and anasarca, Bright's disease, locomotor ataxia, myelitis, tachycardia, apoplexy, paraplegia, progressive muscular atrophy, and, of course, hysteria. I transcribe these diagnoses from the admission registers. Not once in a dozen instances is the diagnosis correct. Now it does not matter so much whether the cases are correctly diagnosed or not provided they are sent to hospital. But there is every reason to believe that many of the cases of ship beri-beri are not sent to hospital, but are treated on board their ships, and that many die in consequence. When we admit a case of beri-beri from a ship we ask if there are any more cases of the disease on board and if there have been any deaths. We are generally told that there are no more cases on board, but that there have been deaths from heart disease, asthma, or some such name, which from experience we know under the circumstances stands for beri-beri. Sailors, we may be sure, are not shipped with active heart disease or with asthma such as would be likely to have a speedily fatal issue. I heard of one instance of a lascar who had been shipped in India as an affective seaman. Within a few weeks he died on board ship, and the cause of his death was officially logged as locomotor ataxia; as if locomotor ataxia ever ran its course in four or five weeks. The man died from undiagnosed beri-beri as many others have done. All this represents a very serious, not to say dangerous, state of matters. Most of these deaths are avoidable. No

beri-beri patient should be allowed to remain in the ship, whether house or ship, in which his disease was contracted; to allow this is like treating a case of alcoholic neuritis with brandy. To treat alcoholic neuritis properly you must first diagnose it, and similarly to be able to treat beri-beri properly you must also first diagnose it correctly. But without special instruction or without an experience bought with human life there is as little chance of being able to diagnose the one as there is to diagnose the other.

Filaria is another tropical disease which is often overlooked, and about which there are many absurd and even dangerous misconceptions. In most tropical countries in which the subject has been investigated, it has been found that about one man in every ten is affected with blood worms. In some places the proportion is as high as one in three, in others one in two, and I know of at least two places where nearly every inhabitant is victimised in this way. Surely, therefore, it is of importance, seeing that these parasites give rise in many instances to grave disease, that the medical practitioner should know something about them, be able to diagnose their presence, and recognise their effects. But ten chances to one if one asks a student, or even a medical practitioner, to set about examining a patient for filaria, he will prepare a very fine film of blood, such as would be suitable for the demonstration of bacteria, and that he would set to work to examine it with a twelfth of an inch immersion lens and an Abbe condenser. Now, although there may be tens of millions of filaria in the patient's blood, the chances are they will not be discovered by such means. Most people think that when they have to make a microscopic examination, the more microscope they have the better. As a rule, the reverse is the truth. Filaria should be sought for with an inch objective, otherwise they will be missed. Though the individual filaria are large as compared to bacteria, they are relatively few in the blood. You require, therefore, to include a large field with your microscope to have a reasonable chance of finding them. If a sailor could command with his eye only the narrow horizon visible from a small boat, he is not likely to see many whales in the sea, so he ascends into the crow's-nest at the mast-head, and, commanding there a wide view, he can see any whale that spouts for miles around. So it is in searching the blood for filaria—a large field is indispensable. But this is a self-evident fact hardly ever grasped by the student unless he has it actually demonstrated to him. He seldom arrives at it spontaneously. Now, exactly the opposite is the case for the malaria parasite. All this needs teaching, needs demonstration. The malaria parasite I tried to find for nearly ten years before, through accident, I finally succeeded. A Chinaman found my first filaria for me. I mention these things to show how necessary it is, if we would save time and make the best of our opportunities, to have someone to teach us even simple technique.

In connection with filaria and blunders in diagnosis from want of elementary instruction in tropical diseases I may refer to a case which I came across. The patient was a handsome young fellow, who some years before had joined a regiment of horse artillery then in India. He got on very well for a year, liked his work, and was

and the right hand in promotion. One day he got a worst pain, not with the fever a pain in his left groin, which he now and for the first time noticed to be swollen. In due course the fever subsided; but as the swelling, which grew and grew until it became the size of a fist. It interfered with his riding, and so he consulted the regimental surgeon. The swelling was soft and to a certain extent reducible. Accordingly a poultice was diagnosed and a truss applied. But the truss caused so much pain that it could not be worn. It irritated the swelling and brought on attacks of inflammation and fever. Getting no better he went to one of the Presidency towns to consult a surgeon of experience in tropical disease. This surgeon recognised at once the true nature of the swelling, diagnosed the case as one of varicose groin glands, confirmed his diagnosis by an examination of the blood, which he found to be full of filaria, and very properly advised the patient to throw away his truss and to give up soldiering. Now a very little instruction in tropical disease given to the regimental surgeon would have put him on the right track, would have spared this patient much suffering, time, and expense, and have reduced to some extent the military burdens of our over-taxed Indian empire.

One more illustration of my contention. In 1895 and again in 1896, Mr. GALGEY, Colonial Assistant Surgeon, St. Lucia, West Indies, sent certain valuable reports to the Government, part of which were subsequently published in one of the leading medical journals, pointing out that ankylostomiasis is very prevalent in St. Lucia and probably all over the West Indies, and narrating his experience of the wonderful efficiency of thymol as an anthelmintic. As many of you are doubtless aware, there is a form of pernicious anemia common among negroes and the natives of hot countries generally. The patient, without obvious reason, becomes breathless, weak, anemic, dropsical, and very likely, after a long and distressing illness, dies. Many years ago, GRIMSINGER showed that the Egyptian form of this disease was associated with—in fact, caused by—a blood-sucking intestinal parasite—the ankylostomum duodenale. In 1880, in consequence of the publicity given to this discovery by the epidemic of ankylostomum anemia among the workmen in the St. Gothard tunnel, this fact of the relation of the ankylostomum to a form of pernicious anemia was thoroughly established. In the same year BOZZOLO introduced thymol as an anthelmintic in this helminthiasis. Experience in Jamaica, Ceylon, Java, Brazil, the Straits Settlements, and elsewhere confirmed GRIMSINGER's discovery of the cause of this anemia and also BOZZOLO's discovery of its curability by thymol. But although these things were well-known in Italy and in many parts of the tropics, their importance was missed by the teachers of medicine in England, and as a consequence the medical men who went out even subsequently to 1880 to the West Indies, went out imperfectly informed in a matter of the highest importance to a considerable section of the people committed to their charge. Thus our fellow subjects, the poor negroes, did not have the benefit of an important advance in medical science and in practical therapeutics until Mr. GALGEY found, fifteen years after it was known in Europe, that ankylostomiasis was the cause of the anemia of the negro and that thymol could cure it. Who can estimate the

number of lives that might have been saved if tropical medicine had been taught to our West Indian colonial surgeons, and if they had gone out thoroughly informed on the subject of ankylostomiasis? Mr. GALGEY writes that in the six years 1890-95 there were 72 deaths in the hospital of Castries, St. Lucia. In the year 1896—that is to say, since he diagnosed the nature of these cases and treated them efficiently—he informs us that there was not a single fatal case of this disease. From this we are entitled to infer that the seventy-two deaths from pernicious anemia occurring in the preceding six years were from ankylostomiasis, and that these seventy-two lives might have been saved. That is to say, an average of twelve lives a year. Or, assuming that this mortality had been going on ever since 1880, the date of the discovery of the anthelmintic properties of thymol, we must conclude that in the hospital of Castries alone 180 people died whose lives might easily have been saved. But this is not all. There are four or five hospitals and dispensaries in St. Lucia, and as there is no reason to suppose that ankylostomiasis is confined to the Castries district of the island, we are forced to conclude that in these fifteen years about 900 have died unnecessarily in St. Lucia. St. Lucia is one of the smaller West India islands. Although I know that thymol has been in use for some time in British Guiana, I do not know that, except in the hospital in Kingston, Jamaica, it has been generally employed in the neighbouring archipelago. I also know that the existence of the ankylostomum has not been recognised, at all events until very recently in many of the islands. The avoidable mortality from ankylostomiasis therefore for the whole of the West Indies during these fifteen years must run into tens of thousands. This is a serious indictment against our present system of medical education, and the worst of it is that what holds good for ankylostomiasis holds good for a dozen other tropical diseases, some of them perhaps not so serious as ankylostomiasis, but some of them even more serious.

I fear that, as so often happens in medical lectures, I have spent so much of my hour in describing the symptoms and pathology of this disease of the body medical that I have little time left in which to speak of that very practical matter, the treatment. I hope, however, I have convinced you that we are speaking of a very grave disease in our educational system, and that there can be no question about the diagnosis and the indications for active and prompt treatment. I have my own ideas about the latter, but as the responsibility in the case is serious, I have called in a specialist of experience to prescribe. I need hardly say I fully endorse his prescription. Dr. ANDREW DAVIDSON writes:—"I do not think that attendance on a course of lectures on tropical medicine should be made a part of the ordinary curriculum. It seems to me, however, urgently necessary (1), that a course of lectures on the hygiene and diseases of warm climates should be instituted in each medical school; (2) that a certificate of qualification in these subjects be granted by the licensing bodies after examination to those who have attended this course of lectures; and (3) that the Government should encourage the study of tropical pathology by giving a preference to those possessed of this certificate if equally proficient in other subjects, and that

appointments made from home of medical officers for tropical and sub-tropical colonies should be restricted to men holding this qualification." If these suggestions are acted on, not only would vast benefits accrue to the natives of warm climates and to those Europeans who have to reside among them, but an enormous impetus would be given to tropical pathology and therapeutics, and, doubtless, indirectly to medical science in general. By instituting a lectureship on tropical medicine St. George's Hospital has done its share in encouraging this necessary reform in medical teaching. Other schools are following our lead; but be the schools ever so willing to second each other without the co-operation of the General Medical Council, they can do but little. As Dr. Davidson suggests—and it is the General Medical Council that can alone give effect to the suggestion—there should be a special examination and some kind of diploma for tropical medicine, and Government should countenance and encourage it. If this reform be carried out of one thing I am sure, and that is that those of you who in the future may go abroad to practise your profession will bless the General Medical Council for forcing you to qualify yourself for your work.

—————:0:—————

THE PROGNOSIS IN CARDIAC DISEASE.*

By J. E. GRAHAM, M.D., M.R.C.P. Lond.

Professor of Medicine and Clinical Medicine, University of Toronto; Physician to the Toronto General Hospital and St. Michael's Hospital.

THE fact that some of the most serious and suddenly fatal forms of disease are at times preceded by so few symptoms will always make the prognosis in cardiac disease one of the most difficult questions in clinical medicine.

In the first half of life valvular lesions are the result of endocarditis, and the prognosis depends largely on the nature and degree of the infection, the particular micro-organism present and the resisting power of the constitution. For instance, endocarditis resulting from scarlatina is not likely to recur, and other being equal, is on that account more favorable than the form due to rheumatism.

It is difficult to determine whether the systolic bruits, which occur during an attack of rheumatism, have been caused by changes in the heart valves or in the blood; and while the immediate prognosis of endocarditis occurring during a rheumatic attack is usually favorable, the liability to recurrence renders the future more uncertain, though after 40 years of age recurrent attacks of rheumatism generally cease, and if they do occur, they are not so likely to be accompanied by fresh attacks of inflammation of the endocardium. Rheumatic endocarditis is often fatal in young children owing to the pressure, also of pericarditis and myocarditis.

Though in nearly all the cases where it lasts from the beginning to the end of an attack of rheumatism, the endocardial murmur never disappears in after-life, the physician should not alarm the friends of the patient by predicting serious heart-disease simply because he dis-

covers a heart murmur during an attack of rheumatism. For even when the endocardial murmur exists throughout the greater part of an acute attack, complete recovery and perfect reparation takes place in a certain proportion of cases. Thus LATHEM records 17 and GIBSON 25 recoveries out of 63 and 51 cases respectively.

Then, as a very little over-exertion may very much increase the gravity of the prognosis, which during the period of establishment of compensation depends largely on the behaviour of the patient and the treatment adopted, it is imperative to ascertain (1) the (a) extent and (b) the duration of the lesion and (c) the changes it has caused in the heart itself. (2) presence or absence of other diseases, (3) condition of the other organs, (4) hereditary tendencies and (5) the temperament, life habits, surroundings and 'calling' of the patient.

Auscultation *per se* does not give definite conclusions and many writers complain that the stethoscope has done very little in the prognosis of cardiac disease; but when these two methods are combined with the powers of observation possessed by the older physicians, they are efficient aids to estimating the extent of lesion during compensation and, which is of more importance, the completeness of the compensation estimation.

In *mitral insufficiency*, which is the most frequent and the least serious of valvular lesions, the development of subsequent changes is slower than in any other. When not the result of mitral lesion, mitral incompetence is due to dilatation of the ventricle from anæmia, acute febrile diseases, old age or lesion in the other valves, and when found in acute febrile diseases or anæmia, complete recovery may take place, while in old age it may exist when there is only a moderate dilatation of the ventricle, and this condition, which always indicates a weakened myocardium, may exist for years.

The accentuation of the pulmonary second sound is of value in diagnosing a very slight from a very large amount of regurgitation; but when the right ventricle has given way to some extent, this sound may not be heard at all, and a most serious condition of the heart is indicated.

Irregularity of the pulse is a sign of failing compensation and the volume and tension of the pulse falls when there is much regurgitation.

The heart being nearly normal in size and there being no other evidences of serious lesion, the musical sound of the mitral murmur, produced by a narrow slit-like opening due to imperfect closure of the segment of the valves, is the indication of a 'slight amount of regurgitation,' which is also indicated by a late bruit, of an almost post systolic character, or a small volume of sound; but it must also be remembered that the musical sound may result from one of the chordæ tendinæ in the blood current, while in extensive mitral lesions of a serious nature, when the heart is much enlarged and the force of the valvular contraction is not great, a soft murmur of small volume may occur, a very loud mitral regurgitant murmur may exist when the lesion is slight. Thus FARROTT mentions a case who lived 20 years, during which his heart sounds could be heard across a billiard table, but died from acute dilatation due to over-exertion, and the author

* Read before the Toronto Medical Society and specially reported for the *Indian Medical Record*.

had a case whose 'late systolic murmur' could be similarly heard, but who recovered.

As far as volume of sound is concerned, mitral insufficiency may be divided into four classes: (1) A slight murmur in a fairly healthy heart indicates small lesion. (2) A loud murmur at the apex, under scapular angle and at the spine, tells of an extensive lesion, dilated ventricle and a strong myocardium. (3) When the bruit replaces the second sound a more serious lesion and want of closure of the valves are indicated; but (4) extensive disease and a weak myocardium are betrayed by the soft blowing sound with a dilated heart.

In aortic stenosis scant reliance can be placed upon the volume of sound, as an aortic systolic murmur indicates stenosis in a certain proportion of cases only; but a loud systolic aortic murmur decidedly lessening in volume betokens weakened myocardium and a serious prognosis, which latter may be enhanced if dizziness or fainting fits be present since they point to cerebral anemia. The absence of constitutional disturbances, together with the continued loudness of the murmur, offer a fairly good prognosis as long as there is compensative hypertrophy indicated by the size and shape of the left ventricle, the apex beat being downwards into the left. The pulse in aortic stenosis is small, long and tense.

Mitral stenosis has three stages: (1) where the aortic second sound is heard clearly at the apex, (2) where it is absent at the apex, and (3) where the pre-systolic murmur is absent, owing to dilatation of the right ventricle and tricuspid incompetence. The pulse is usually small and may be compressible or tense. Owing to the decreasing tendency of the opening and to the force of the right ventricle resisting the reflux into the ventricle while it fills the ventricle more rapidly in diastole, the prognosis is not very favorable and less so in children than in adults. If there are signs of pulmonary hemorrhage, hepatic enlargement and dropsy in addition to (a) the tricuspid regurgitant murmur, (b) the venous pulse in the neck, and (c) the absence of accentuated pulmonary second sound, prognosis is grave indeed.

Aortic insufficiency is less dangerous when it comes on in early adult life, because compensatory hypertrophy takes place more readily than in later years. When aortic disease results from syphilis, the prognosis is unfavorable and anti-syphilitic medication useless. The pulse should be carefully examined, and if it is distinctly collapsing in character it indicates a great amount of insufficiency; but the loss of elasticity of the vessels may prevent the collapse being noticed, while in cases of grave prognosis a collapsing pulse may be prevented by (1) aortic stenosis preventing the return of blood to the heart, and (2) failure of the heart muscle with too feeble blood propulsion to produce a collapsing pulse. The delay of pulse, due to emptiness, intonicity or enlargement of the vessels, is most marked when there is much regurgitation, and irregularity in the frequency and force of the pulse occurs in the latter stages of the disease.

When compensation has taken place, the size of the heart is in proportion to the regurgitation. The murmur is often more favorable when it is long and loud than when it is difficult to hear, and when it takes the place

of the second sound, the amount of the regurgitation is greater than when the click of the closing valves is heard in addition to the bruit; but the presence of the pre-systolic and systolic murmurs is of serious import as they indicate great dilatation of the left ventricle.

Aortic stenosis sometimes exerts a beneficial effect on regurgitation by preventing the rapid emptying of the aorta into the left ventricle. Tricuspid regurgitation is a severe lesion whose severity is all the more serious when it occurs as an independent disease, as it is the (1) result of serious changes in the mitral and aortic valves, and (2) the walls of the right ventricle do not undergo compensative hypertrophy as those of the left do. The following is the grade of gravity in the comparative prognosis of the different valvular lesions:—(1) tricuspid and (2) aortic insufficiency, (3) mitral and (4) aortic stenosis, and (5) mitral insufficiency.

The prognosis is always more favorable during childhood and early adult life, when valvular lesions are generally the result of inflammation, than in those occurring after middle life, and which are often caused by degeneration when the recuperative powers of the heart are much diminished. The presence of lesion of two sets of valves increases the gravity of the case, but patients suffering from double lesions have lived for many years. Mitral stenosis which comes on in childhood, is more serious than that which occurs in early adult life, and it is quite probable that from year to year changes do take place in the affected valves as the result of either chronic or sub-acute endocarditis. Rupture of a segment of valve is usually fatal, though cases are recorded where patients have lived for weeks after such a lesion.

The condition of the other organs of the body should be faithfully examined, as enlargement of the liver, venous stasis, oedema, albuminuria are unfavorable symptoms, which become serious indeed when they follow the period of compensation, though their prognosis becomes more favorable if they are results of overwork or if rest is followed by a decided amelioration of symptoms. The liver should always be examined carefully as it is often an indication of the condition of the right ventricle.

The social condition of the patient may be an important factor, and if he have ample means and the wish to take care of himself, he will probably live much longer than the one who has to struggle to support himself and family, yet the rich man may weaken his endocardium by becoming indolent or drinking too much. Tobacco acts deleteriously on the system, and is often the cause of serious changes in the heart. WHITTAKER notes that a man may smoke for 15 or 20 years without injurious effects when suddenly symptoms of nicotine poisoning may develop. Alcohol has an injurious effect, especially in the production of arterio-sclerosis. Sex has an important bearing. Mitral stenosis is more frequent in the female and aortic insufficiency in adults. BROADBENT says when the valve disease comes on in childhood, girls break down at the period of puberty more often than boys.

Hereditary tendency plays a very important part in the prognosis of cardiac disease, and though the heart symp-

forms are sometimes altogether out of proportion to the extent of the disease, there is always the possibility of congenital shortcomings getting worse, or of an attack of infective endocarditis from accidental introduction of disease germs into the circulation, or of arterial sclerosis or Bright's disease exerting a very deleterious influence on a heart weakened by valvular disease, and it is well known that a valve already injured often becomes the seat of an ulcerative process or degeneration.

Sometimes grave symptoms such as dyspnoea and tendency to syncope may exist and may not be entirely due to cardiac lesions, or a patient with slight mitral lesion may have palpitation or irregular action due not to heart but to digestive disturbances; or, again, sickly persons past the middle age of life but in whom there is no valvular lesion may have a feeling of oppression and other dyspeptic manifestations of extremely grave import, or of comparative unimportance and of a temporary character. Hence the necessity for estimating the actual extent of the lesions which at first appear more formidable than they really are.

A high tension pulse, from whatever cause, is unfavorable as it increases the heart's work and the presence or absence of anæmia (particularly), bronchitis, albuminuria and other diseases greatly influences prognosis in valvular lesions. Thus in old people there is a natural limit due to weakening of the myocardium and an attack of bronchitis will precipitate the most serious symptoms; so also will over-feeding and alcoholic indulgence.

Valvular lesions, which have originated after the middle period of life, are usually the result of various forms of degeneration, and lesions more frequently of the aortic than of the mitral valve, but they are often the direct result of an infection, and when systolic and diastolic aortic murmurs in elderly persons, are accompanied by fever, the prognosis is usually unfavorable.

Aortic disease accompanying degeneration of the arteries is probably of slow development, but the changes have already taken place in the majority of instances of persons seeking treatment, and in double aortic bruits there is always the possibility of aneurism on the sinuses of Valsalva.

Mitral incompetence, indicated by the mitral systolic murmur heard first at about the third interspace and afterwards at the apex, depends on dilatation of the left ventricle, whether from senile heart, or degeneration of the myocardium, or depressing mental emotions or sudden over-exertion.

Valvular murmurs cannot be heard in weakness of the myocardium, due to (1) local or (2) general fatty degeneration. The (1) local form, which is the result of endarteritis or atheroma in the coronary vessels, is extremely difficult to diagnose and occasionally tends to rupture of the heart, while the presence of (2) general fatty degeneration, which is often the result of an acute infectious disease, such as typhoid fever, is manifested by the character of the first sound and of the effect of exercise upon the heart's action. General fatty degeneration of the heart muscle, sometimes found in elderly people, may result in sudden death without the patient ever suspecting his heart was affected.

Attacks of syncope are very grave in elderly patients with symptoms of weakened myocardium; but they are not so dangerous when the patient belongs to a family subject to fainting fits.

When angina pectoris is the result of over-fatigue only or excitement or of indigestion, the attacks may be warded off by removing the cause; and when it occurs in aortic valvular disease, it sometimes runs a protracted course; but if there is marked tension of the pulse during an attack, there is some danger, and the cases which cause the greatest apprehension are those in which the cardiac impulse is slight and the sounds are weak.

In angina, fatty degenerations, prolonged diastole from cerebral anæmia, diseases of the coronary arteries and in all cases where advanced cardiac diseases are accompanied by dyspnoea, dropsy, pleuritic fusion &c., there is a possibility of sudden death, but there is no risk of any of the valvular lesions except aortic incompetence making a person fall down dead.

Prognosis of cardiac neuroses.—Palpitation is hard to cure and may hang on for years, but it is not usually of serious import. The paroxysmal form of bradycardia usually terminates fatally in elderly persons and so also does paroxysmal tachycardia. Arrhythmia is more grave than palpitation; but its gravity depends on whether the cause can be removed or not. When due to alcohol, tea, coffee, or indigestion, careful treatment may cure it; but when it is due to heart failure and Bright's disease, it is a serious symptom: Yet people with Arrhythmia may live for years. Focal arrhythmia indicates a very late stage of valvular disease with dilatation due to weakness from fever.

:C:

WIDAL'S REACTION IN NATIVES OF INDIA.*

By W. C. BROWN, M.D.

Penang.

THE article on the supposed immunity of Natives of India to typhoid fever, by Surgeon-Major FREYER,¹ re-opens a question which has long been of great clinical interest, and deals with it from the advantageous diagnostic basis that has been obtained by the application of serum diagnosis.

The theory that almost the whole adult native population gains immunity from typhoid on account of universal prevalence of the disease in the form of mild and unsuspected attacks in infancy—that, in short, typhoid is so rare in adults because it is so common in infants—is not a new one. It has been propounded by several authorities on Indian fevers, and is referred to in an able article on tropical typhoid by Surgeon-Captain WHITHEAD.² Surgeon-Major FREYER adopts the view that natives, generally speaking, are immune to typhoid fever; and concludes, on what I venture to think is insufficient evidence, that this doctrine of immunity is confirmed by some remarkable experiments, in which he found that the blood serum of healthy natives gave positive reaction to WIDAL's test. Surgeon-Major FREYER, therefore, advances the three propositions:—

1. That natives of India, generally speaking, are immune to typhoid fever.

* Reproduced from the British Medical Journal by consent.

2. That a single attack of typhoid in childhood confers permanent agglutinative powers on the blood serum.

3. That, generally speaking, the blood serum of healthy natives of India gives a positive reaction to Widal's test.

Perhaps it will be best to look at the last of these propositions first, and to see what are the results of the examination of the blood of healthy natives, and the consequent general applicability of WIDAL's test in India. In venturing a clinical and bacteriological criticism of Surgeon-Major FREYER's views, I would say that my clinical experience of natives of India has been limited to them as immigrants in the Straits Settlements in their various capacities of merchants, traders, sailors, servants, and coolies. I have, however, made numerous serum tests of their blood, chiefly for diagnostic purposes, and have compared the results with those obtained in Malays, Chinese, Burmese, Siamese, and other nationalities. So far I have not found that the serum reaction of natives of India differs, either in health or disease, from that of Europeans or other races. The sanitary conditions that surround these other Oriental races are little, if at all, better than those of India.

In the appended table of the results of examinations of the blood of 15 natives of India of different castes, the first 8 were consecutive tests for WIDAL's reaction in the course of ordinary practice, Nos. 2 and 3 being control tests. The remaining 7 were the first of a large number of examinations carried out on healthy natives after I had read Surgeon-Major FREYER's article. It is difficult in the face of these results to come to any other conclusion than that the blood of healthy natives of India does not possess any special agglutinative power.

The basis on which Surgeon-Major FREYER's conclusion rests is his acceptance of the theory that a mild attack of typhoid in childhood will confer a permanent aggluti-

native power on the blood serum, but such a deduction is directly opposed to all the evidence which is before us as to the reaction, and is entirely contrary to the whole theory of serum diagnosis. No hard-and-fast rule as to agglutinative power or permanence can be laid down. In the blood serum of one and the same typhoid patient it varies from day to day. Sometimes it increases with convalescence, sometimes it decreases; before death it is sometimes greater sometimes less; and so with its duration. But a primary characteristic of the reaction is that it is one of infection and not of immunity. The theory that the presence of EBERTH's bacillus causes the secretion by the blood of an antitoxin which remains permanently in the system after a successful fight with the bacillus, is a beautifully simple theoretical explanation of the reaction, but it is disproved by observation.

The time of the disappearance of the phenomenon after typhoid fever, like the tenacity of the agglutination, varies in different subjects; and according to WIDAL and SICARD³ it is generally quite gone in two or three months after defervescence; and in one case they observed it disappear completely on the eighteenth and twentieth day.⁴ ACHARD and BENSAUDE failed to get the reaction ten days after fever had ceased; and BARWEN, THIEROELIN and LENOBLE had the same experience. COURMONT⁵ followed the progressive disappearance of the reaction in a child, and found the blood lost its agglutinative power completely in two months. In three children whom C. FRAENKEL attended for mild attacks of typhoid fever, he found no reaction after some days of convalescence; and EUG. FRAENKEL fixed the date of disappearance as the twenty-eighth day.⁶ All the evidence at hand goes to prove that in mild attacks the blood serum loses its agglutinative power sooner than in severe ones. In two severe cases in children I have found a positive reaction in the three months after defervescence, and they are

Table of Results of Widal's Reaction in Natives of India.

	Name and Age.	Class or Caste.	Native of	Reaction.	REMARKS.
1	M., 18*	Hindu	Madras	Negative	A case of puerperal mania; patient had just recovered from severe puerperal fever.
2	V., 35	Hindu	Madras	Negative	Patient was quite healthy; never had any illness that he knew of except malaria.
3	S., 27	Christian Tamil	Madras	Negative	A control experiment; patient was quite healthy; said he had never been ill in his life.
4	S. M., 35	Mati	Southern India	Positive	Test carried out for diagnostic purposes on the eleventh day of illness; dilution 1 in 14 and 1 in 20; both positive. Patient died with marked symptoms of typhoid.
5	S. C., 29	Hindu	Tanjore	Negative	Test for diagnostic purposes; case turned out to be malarial fever; recovery in four days.
6	Sh. C., 10	Hindu	Coromandel	Negative	Diagnostic test made on sixth day of fever; patient recovered about eleventh day, malarial parasite found.
7	P., 26	Hindu Pariah	Negapatam	Positive	Patient very ill; recovered after severe hemorrhage from bowels.
8	D., 16*	Christian Tamil	Southern India	Negative	A case of malarial remittent fever; blood examined many times; parasites always present.
9	M., 25	Hindu	Southern India	Negative	Patient was quite healthy.
10	R. S., 29	Sikh	Punjab	Negative	Patient was healthy.
11	P., 40	Hindu Pariah	Madras	Negative	Patient was healthy.
12	W. L., 30	Burmese	Madras	Negative	Patient had hepatitis.
13	S., 19	Hindu	Negapatam	Negative	Patient was healthy.
14	K., 18	Hindu	Tanjore	Negative	Patient suffering from measles.
15	R., 20	Hindu	Madras	Negative	Patient was healthy.

*Female.

still under observation; but in mild cases where the reaction was marked during the course of the fever, I have not known one positive reaction after the fortieth day. Though it is true that a previous attack may detract from the absolute reliability of WIDAL's test, it is abundantly proved that a mild attack of typhoid cannot confer general permanent agglutinative properties on blood serum.

In the examination of blood serum in the tropics the great source of error is the formation of false clumps—a phenomenon which takes place more frequently and more rapidly than in temperate climates, and is due to the different conditions of the surroundings and not to any difference in the blood serums. It is absolutely necessary to use a virulent culture of bacillus, with a dilution of 1 in 10, and to fix a short time limit, say fifteen minutes, certainly not longer than twenty. All the recent evidence before us points to the necessity of shortening the time limit in order to get accurate diagnostic results. Results based on lengthened observations are quite unreliable.

As to the question of the immunity of natives to typhoid fever, more careful diagnosis and more systematic post-mortem examinations are showing us that their exemption is not nearly so great as has been supposed. In the older native hospital statistics, published by the Government of the Straits Settlements, typhoid fever had no place; but, in the municipality of Singapore, with a population of about 100,000, the health officer reported in 1896, 186 cases of typhoid; 55 of the worst cases were sent to hospital; and of them 46 died. The diagnosis was verified in all, or nearly all, by post-mortem examination. Natives have little, if any, less immunity to the disease than acclimatised Europeans, and the universality of typhoid fever and typhoid infection is now fully admitted. And, more, we have the strongest reasons for believing that the Eastern tropics are not only the home but the birth-place of typhoid fever. The universality of malaria and the difficulty of obtaining post-mortem evidence in native practice have been the causes of error and serum diagnosis has come only to confirm an opinion which was already partly established.

Typhoid is mostly a disease of acclimatisation, but its prevalence during that period is due to the fact that the mucous membranes of the alimentary canal then offer from a variety of causes a more congenial soil to EBERTH's bacillus than do those of older residents. It is not the case that new arrivals gain immunity by passing through a mild attack of the disease. The acceptance of that theory, and of the permanent agglutination hypothesis, would involve us in the conclusion that not only every adult native, but every European in India, would react positively to WIDAL's test which would therefore be useless. The test has already proved of the greatest value in the tropics, and has elucidated many difficulties in the study of the phenomena of tropical fever.

A MIRROR OF PRACTICE.

A CASE OF ENTERIC FEVER COMPLICATED WITH DOUBLE PNEUMONIA.

BY ASSISTANT SURGEON E. S. PUGHONG,
Station Hospital, Lucknow.

THIS case, which I venture to publish, had nothing in any one symptom or any one group of symptoms different or striking in comparison to any symptom or symptoms common to any marked case of enteric fever, with the exception that pneumonia presented itself as a complication.

It is more for the system of treatment adopted, rather than the mere enumeration and publication of the clinical features of the case that I have ventured to send the following notes. It would not be out of place here, however, to give the clinical presentations of the case from the time the case came under my observation to the period of convalescence.

On being called in to see the case, I found that the boy, aged 18, had been ailing for about 14 days with fever, his temperature having ranged between 102° and 103°F, occasionally reaching 104°F, at which point I found it the evening I saw the child.

The history given was that the child had felt unwell for a few days before he took to bed, having complained of severe frontal headache, general disinclination for any amusement, and loss of appetite: in short all the preliminary symptoms of a fever.

The fever, which no doubt was but slight at first, then began to show rather an active form, ranging between 102° and 103°F. He had slight diarrhoea for a couple of days, but was constipated when seen by me.

The boy also complained of a troublesome cough, accompanied by slight pain in the chest. I noticed also the breathing was very hurried and shallow in character.

This condition naturally directed my first attention to the examination of the chest, where, on inspection, I found all the indications of consolidation of both bases of the lungs.

The peculiar bright-eyed appearance and heavy, necrotic typhoid smell led me to first examine the abdomen, which I found greatly distended, being quite tympanitic on percussion. On passing my hand over the right iliac and applying firm pressure with the palm, and exercising a right to left movement, I was able to get a distinct gurgling, the patient complaining of tenderness.

Notwithstanding the great distension of the abdomen I found that both the liver and spleen were somewhat enlarged.

A few characteristic rose spots were to be seen on the lower abdomen.

Though the temperature had persisted with a marked activity, yet the symptoms classifiable under the heading of "nervous system" were but few, viz., slight frontal headache, restlessness and slight blunting of the perception.

Tongue was quite dry and leathery with a central brown patch, which condition only truly spoke of the extent of ulceration.

I saw the boy three days after and found that the lung was now full of crepitant rales the sputum being still rusty and tenacious. There was no change in the run of the temperature.

It was stated, however, that he slept well and took his nourishment better.

His pulse, which was very weak when I first saw him, had now improved and was much stronger.

The case progressed favorably, there being gradual improvement until convalescence was reached, which covered a period of over four weeks.

Treatment.—The case being recognised as that of enteric fever complicated with pneumonia and the self-limited nature of the case being considered, the line of treatment adopted was that covered by the following words :—

“Keep the temperature within reasonable limits and nurse your patient through.”

Adhering to this, directions were left that a powder of Antifebrin grs. ii with brandy ℥i had to be given whenever the temperature rose above 102°4 F, which had to be taken every two or three hours.

A mixture consisting of :—

R. Liq. Ammon. Acet.	℥iss.
Spts. Æther Nitr.	℥i xv.
Vin. Ipecac	℥i v.
Aqua ad	℥i.

was given every two hours with ℥i of brandy, and a cough mixture every four hours, *vis.*, with every second dose of the fever mixture, containing :—

R. Ammon Carbonas	grs. iii.
Tr. Scillæ	℥i iv.
Vin. Ipecac	℥i v.
Infusio Senega ad	℥i.

Both bases were painted with equal parts of Tincture and Liniment Iodine, and chest was wrapped in flannels

The Antifebrin powders of course, accordingly as the case progressed, became fewer and fewer daily until not required at all.

The temperature having towards the end taken on an intermittent type of fever, small doses of quinine were ordered to be given every morning.

Diet.—At first solely milk, but as the case progressed, broths were ordered, with egg-flip in the morning, until gradually solids were allowed.

The case having convalesced, change of climate and the use of Coca wine was recommended.

Remarks.—It has been the seeming general prejudice among a large number of professional men against the antipyretic system of treatment, that has led me to await an opportunity to be able to publish the results of a case so treated, and which has occurred solely under my own care, though I have been an eye-witness in the treatment of no less than fifteen cases of enteric fever occurring under the care of my father, Mr. A. L. PUGHONG, all of which, I am proud to say, have recovered, and to-day bear a living testimony to the sound, yet simple and efficient, line of treatment based upon common sense. I have noticed that the delirium, so common a feature in the

severer cases at the middle or end of the second week, did not occur in the cases so treated.

There has been no hemorrhage, blunting of the perception, sleeplessness, restlessness, that high state of nervous excitement accompanied by muscular tremor on any slight exertion, so often seen in cases of the severer type treated otherwise. In no one instance has there been any unwonted depression caused by antifebrin, which has never been given in doses over three grains and without brandy, though in some of the severe cases during the second week, when the fever has been in full activity, a powder has been even given every hour for several hours in succession; of course this stage of a rushing temperature rarely lasts over a couple of days, when the fever will be found to begin to lose its activity, by that I mean that a powder which only kept the temperature within reasonable limits (101° to 102°F.) for say one hour, would, when this stage of tending activity be verged upon, keep the temperature down for 2, 3, 4 or 5 hours as the case progressed, so that not only is the powder found to be beneficial in helping to steer the case through, but is a sure guide as to how things stand; for one can almost gauge the day from when the fever begins to decline and improvement begins to be established.

I must, however, confess that the period of convalescence may be somewhat prolonged.

HUGE PUTRID ABSCESS OF BROAD LIGAMENT: THREATENING PERITONITIS: VAGINAL INCISION AND DRAINAGE: RECOVERY.

BY JAMES R. WALLACE, M.D., F.R.C.S.I.,

Fellow of the Obstetrical Society of London, Formerly Resident Surgeon, Eden Hospital for Women and Children, and Resident Surgeon, Medical College Hospital, Calcutta, &c., &c.,

ON the 20th March 1898, I was asked by a medical man in the suburbs of Calcutta to see one of his patients. Mrs. L—, a Scotch lady of 30 years of age, who was suffering from pelvic inflammation. There was a history of a miscarriage of a two months' conception which had taken place two weeks before I was called in. Intermittent bleeding had followed expulsion of the uterine contents, and on the 7th day after the mishap fever set in and the discharges became foul, while at the same time severe pain was felt in the abdomen, and the uterus and its appendages were very tender and surrounded with an ill-defined swelling. When I saw the patient, her temperature was 104°F, the abdomen was tumified and tender, there had been much vomiting all that day, and she was very depressed and low. She was chloroformed and the uterus was quickly dilated with a set of silver-plated Hegar's dilators and the uterine cavity was thoroughly curetted. Several pieces of putrid membranous remnants were removed, and the uterus and vagina were plugged with iodoform and boric acid gauze. There was a remarkable subsidence of pain, fever and vomiting for three days, and during this time the vagina was douched with a solution of bichloride of mercury with which laudanum was mixed. On the 26th March, the pain and

fever returned, associated with a very marked swelling of the abdomen and a filling up of both sides of the pelvic cavity with effusion, which bulged into the vaginal cul-de-sac. There was also a recurrence of the most distressing vomiting. On the 30th March, fluctuation was evident, and I aspirated the pelvic mass vaginally, and draw off six ounces of thick, putrid-smelling, sanguine-purulent matter. As the patient was very low, and as the abdominal tenderness was very acute, it was feared peritonitis might supervene, so at the suggestion of her regular medical attendant, the patient was brought into town and placed under my care. Next day I found the pelvic mass larger than before, and I decided to make an incision into the centre of it through Douglas' pouch, to insert a glass drainage tube and flush the cavity with boiled water. This procedure was accordingly adopted. About a pint and a half of horribly putrid-smelling pus followed the vaginal incision, and a GAZIG SMITH'S glass drainage tube (8" x $\frac{1}{4}$ ") was quickly adjusted into the opening. The pelvic cavity was irrigated and the vagina was gently filled with iodoformised boric gauze. An hour before the operation the temperature was 106° F, there was incessant vomiting, there was marked tympanites, and the patient could not straighten her limbs but kept them flexed to avoid pain. She was so exhausted that I feared to give her chloroform, and so the operation was performed without any anæsthetic. It was done quickly and the patient bore it most pluckily and well. Within an hour the temperature fell to 100° and it never rose beyond 101° during the three weeks of her subsequent easy and uneventful convalescence. Every unpleasant symptom was completely relieved by the operation. Perchloride of mercury irrigations of the vagina were kept up for a fortnight and the gauze packing was continued for a week, though the glass tube was removed on the second day following the operation.

On the 18th April, the patient was well enough to go to her suburban home and she was seen and carefully examined by Surgeon-Lieutenant-Colonel R. HAVELOCK CHARLES, F.R.C.S.I., on this date. There was still some inflammatory deposit impeding the mobility of the uterus, but it was thought the patient might safely pass out of my hands, with the caution that she was to be fairly restful and avoid sexual exercise for at least two months.

Remarks.—This case pointedly illustrates the excellent surgical value of vaginal incision and free drainage in cases of abscess of the uterine appendages especially does it prove that this procedure may obviate the more dangerous operation of laparotomy.

ACUTE ABDOMINAL DISTENSION IN CHILDREN.

Dr. GEORGE F. STILL, Great Ormond Street Hospital, in *Pædiatrics* for September 15th, 1897, says that this condition occurs as a late complication of diseases, not primarily attacking the digestive tract, and common with bronchopneumonia. While not necessarily a fatal complication, it certainly is a dangerous one and often hastens death. He relates five cases, one of which recovered. He gives post-mortem reports of the other four, showing in photographs first the abdominal distension, and second the visceral distension after opening the cavity. In one case the distension was in the ascending and transverse colon, in a second in the small intestine, and in the third in the stomach. It should be vigorously combated by position, passing tubes, and by enemas. —*Canadian Pract.*

THE Indian Medical Record.

16th May 1898.

A BILL TO AMEND THE LAW RELATING TO THE MUNICIPAL AFFAIRS OF THE TOWN AND SUBURBS OF CALCUTTA, AND TO AUTHORISE THE EXTENSION OF THE SAME TO THE TOWN OF HOWRAH.

In the above Bill there are some points of particular interest to the medical profession, to which we think it will be as well to invite attention.

The most important of these will be found in Chapter XXXIII which deals with the "Restraint of Infection." Section 535 is as follows:—(1). Every medical practitioner who treats or becomes cognizant of the existence of any dangerous disease in any private or public dwelling, other than a public hospital, shall give information of the same with the least practicable delay to the Health Officer."

The "cognizant" portion of this section may be disregarded, for it would be impossible to prove cognizance or fix any responsibility on the practitioner unless he was actually treating the case, or brought into connection with it in a professional capacity.

In another way this section is ineffective, for there is no definition of what is meant by a dangerous disease, a dangerous disease is presumably a disease dangerous to life as heart disease, or Bright's disease, but it can hardly be imagined that the Bill contemplates the notification of these diseases.

It appears to us that the word *infectious* has been omitted by some oversight, and that the section is intended to refer to *dangerous infectious diseases*: even so there is a difficulty in deciding as to what diseases are to be considered as coming under the designation. Would tuberculosis be included, or measles, or whooping cough?

It is obvious that medical practitioners might hold, and would be fully justified in holding, different views upon this subject.

It is the duty of people who draft laws to construct them so that there can be no doubt as to what is intended; to this end it is necessary that all the diseases which are to be notified under this Bill should be specifically mentioned.

This is the course adopted in the English Notification of Diseases Act.

We have looked through the Bill in vain to discover what remuneration is to be made to private practitioners for this extra duty which the Municipality imposes upon them. We can find no mention of any, but we trust that this important omission will be rectified.

It is something of an innovation for a Municipality to bring in a Bill to force people to work without pay, and if the innovation were successful, there is no reason why it should stop at the medical profession. Engineers are very useful to such a body, surely a clause could be introduced by which they would be forced to submit plans.

of sanitary work free of charge, and put the legal profession. We have a wide field for their labours under this Bill. Surely they ought to give their professional knowledge free of cost.

A Municipality that worked on these lines should be very prosperous and show a large surplus at the end of the year.

SHOULD DOctors WORK FOR A MUNICIPALITY FREE OF COST.

We have however before maintained, and we are still of the same opinion, that these acts are legally beyond the power of a Municipality, and that they amount in fact to acts of oppression, which it will be the duty of the medical profession to unite in resisting.

A private practitioner is a free citizen, who owes no more to the Municipality than any other citizen; he has gained the knowledge necessary to his position by his own energies and at his own cost: he has adopted the medical profession for the purpose of making his living, and for a Municipality to demand his labors for nothing, is simply to make an attempt to rob him.

The section we have quoted is an irrefutable proof of the value of the services of the medical profession to the safety of the community; it is a curiosity both logically and ethically, which admits the value of one's services and in the same breath demands that they should be given to the community free of charge.

There is no precedent in English law to force a physician to notify diseases without a fee; the fee in England is a small one, but it is sufficient to establish the principle, and the fact of its being a small one makes it the more difficult to understand why it is grudged in the present case.

NON-OFFICIAL DOCTORS ARE NOBODIES!

But to continue. Section 536 runs as follows:—

(1). "When any person, in the opinion of the Health Officer or of any *commissioned* medical officer, is suffering from a dangerous disease," etc.

This section, whether intentionally or not, we cannot say, entirely ignores the private practitioner. Is it intended that the private practitioner is to be considered incompetent to pronounce an opinion as to whether a person is suffering from a dangerous disease or not? The Bill, as it stands, directs "every medical practitioner" to report to the Health Officer. Is the Health Officer then to form the opinion?

If this is the case, the private practitioner is absolved from all responsibility under Section 533 (previously quoted), as he is admittedly incapable of knowing whether a person is suffering from a dangerous disease or not.

But if he is not capable of forming such an opinion, why is he directed to report to the Health Officer?

To solve these conundrums is beyond our power. We leave them with our best respects to the framers of the Bill.

REGISTRATION OF BIRTHS AND DEATHS.

In Chapter XXXIV an effort is made to put the registration of births and deaths on a more accurate footing. We learn that the entries relating to the cause of death are in a large proportion of cases wholly untrustworthy. Of the 10 persons who on an average die every day in Calcutta, the returns show that from one-third to one-half have had no medical attendant, and in all these cases the cause of death is more or less a matter of conjecture."

We have to thank the Plague for this sudden interest on the part of Government in the subject of registration of births and deaths. For years all this has been common knowledge and would in all probability have quietly gone on for another half century at least, but for the unwelcome advent of plague in India.

For the purpose of registration, Calcutta is to be divided into as many districts as the Local Government may think fit, and a registrar is to be appointed to each district. Every registrar must live in the district to which he is appointed.

WHO ARE TO BE REGISTRARS OF BIRTHS AND DEATHS.

Who are to be the registrars? Section 546 says:—"The Local Government shall appoint a person to be registrar." From other sections, however, it appears that the registrar must of necessity belong to the medical profession, for Section 556 imposes upon him the duty of giving death certificates to the best of his ability in cases of persons who were not attended in their last illness by a medical practitioner.

To give this duty to any but a medical man would be simply to revert to the very state of affairs which it is one of the expressed intentions of this Bill to remedy, when the registrars were mere clerks who had no medical knowledge.

WHO SHALL LICENSE?

Section 558 is curious. It is as follows:—"The Chairman may grant a license free of charge to any medical practitioner empowering him to grant certificates of death under this chapter." This seems to imply that a favor is being granted, where such is far from being the case.

The author of this section can know very little about the laws relating to the medical profession if he thinks that a medical practitioner requires the sanction of the Chairman of a Municipality, before he can issue a death certificate.

DEATH CERTIFICATES.

The question of the issue of death certificates for persons who have died without medical attendance will probably turn out to be far from such a simple matter as the framer of this Bill seems to think. It is certain that in many cases a medical man would be quite unable to form an opinion of the cause of death without a *post-mortem* examination, and in such cases we do not know how a medical man can legally give a certificate, nor what power a Municipality has to authorize him to do in Calcutta what in England might land him in the dock.

QUALIFICATIONS AND DUTIES OF LICENSED PLUMBERS.

Chapter XX deals with the question of "Licensed Plumbers." The duties to be performed by these licensed plumbers are much more extensive than those usually performed by this class of artisan. Thus under Section 517, they may prepare plans and estimates for the drainage of premises, they may also carry out and repair drainage works, and they must report on the state of the drains in every house in their "Ward" once a year. We do not see that the title of plumbers is applicable to performing such duties.

They are to be appointed by the Chairman, who under Section 315 "shall grant to any persons he thinks fit, licences to act as plumbers." Nothing is said as to the qualifications required from persons appointed to perform these important and technical duties.

Not more than two licences are to be granted for each ward.

Section 315 (4) seems curious; for by it the Chairman cannot refuse to grant such a license to anyone who applies for it, without giving his reasons in writing for such refusal. This seems to us to be putting an utterly unnecessary responsibility upon the Chairman, and as he may not always be competent to discriminate accurately between the technical qualifications of competing plumbers, we do not quite see how he is to carry it out.

A MUNICIPAL PLUMBING MONOPOLY.

It is more important to observe that under Section 318, various works are mentioned which only such licensed plumbers will be allowed to carry out.

It lays down that, "No owner or occupier of a building or land shall allow certain work to be done by any but a licensed plumber." This appears to us to be a rather arbitrary measure and to be an interference with the freedom which is usually supposed to exist between employer and employed.

It seems invidious to draw a distinction in this way between artisans, all of whom may be equally well qualified, and by so doing to grant a monopoly to a few.

Of course a Municipality is free to choose its own servants, in any capacity; but to distinguish them from others of the same class by granting them licenses is a step that we fear will not meet with the approval of the trade.

UNLICENSED MEDICAL PRACTITIONERS.

In a Bill which deals largely with the safety of the people, we think it an omission that no steps are taken to preserve the public from unlicensed and unqualified medical practitioners. Something of this kind is badly wanted in Calcutta; the poor and ignorant, who are unable to discriminate in such matters themselves, should be protected as much as possible against unscrupulous quacks by the law. It must be remembered too that qualified practitioners are compelled to pay a heavy license fee to the Municipality. This should entail protection of their professional position by the Municipality.

PLAGUE IN CALCUTTA.

ACCORDING to the official announcement made on Saturday, 30th April, the plague has at last entered Calcutta. How it managed to pass all the barriers established to check its approach is still a matter for speculation. There is no evidence to show that it travelled overland, nor to indicate the exact part of Calcutta which first became infected, indeed, the curious thing is that the earlier cases appeared in places widely separated, and amongst persons who had not moved their residence for a considerable time.

The current opinion of the hour that it was imported by means of infected rats from ships is plausible enough, but it is an opinion obviously difficult to put to the test of exact demonstration, and dangerous in the present state of our knowledge, to put too much faith in.

OFFICIAL PLAGUE METHODS.

One of the most important questions around which discussion centres is the preparedness of Calcutta for the reception of plague.

For over ten days before the disease was finally diagnosed, suspicious cases had been occurring and the usual precautionary steps taken with regard to them, and it was only natural under the circumstances—and what

should have been foreseen and guarded against,—that these precautionary measures and the marked activity amongst those responsible for the public health, should have been interpreted by the people as "proof strong as holy writ," that the dreaded plague was amongst them.

PUBLIC PANIC, ITS CAUSES AND ITS CONSEQUENCES.

The ominous silence of the Government did not help to allay these fears; on the contrary, it provoked a state of gloomy suspicion, in which congenial atmosphere the fertile Oriental mind brooded and imagined dreadful things.

On the 26th of April, it was evident that an unhealthy state of excitement prevailed amongst the natives in Calcutta. On the 28th there was a special meeting of the Municipal Commissioners; and it was confidently expected that some official announcement would then be made, but silence reigned supreme. This policy has been condemned in more than one Calcutta paper of position, and we join with them in expressing our regret, that this opportunity was not taken to make some statement which would have allayed the excited state of popular feeling.

We do not say that a definite opinion should have been expressed as to whether the disease was plague or not; but we hold that if some enlightenment had been given as to the measures to be taken in case it was found necessary to declare Calcutta infected with plague, it would have done much towards checking the wild rumours that were flying about and doing infinite mischief.

The hands of the Sanitary Commissioner were however evidently tied, and his reply, when asked for some definite statement, couched as it was in the most feeble type of stereotyped officialism, that he declined to reply for "Imperial reasons," cannot be considered fortunate.

To this lost opportunity may be credited the panic that ensued; and here again we have a remarkable instance of the failure of the Government to understand the people of the country. If there was one thing they desired to avoid, it was a panic; if there was one thing more than another to which all their aims, means, and ends were directed, it was to allay all suspicion in the native mind and to keep the population in a quiescent state. How well they succeeded may be judged from the fact, that 200,000 persons are estimated to have fled the city, before even the disease was authoritatively given out to be plague. We read of scare and panic, of a short reign of terror, of deserted markets, and of the whole of the lowlier portion of the community deserting their work and flying for their lives.

Had the Government delayed their announcement another day or two, it is impossible to imagine what the result would have been; for curiously enough, as soon as the announcement was made and some of the measures to be adopted published, the panic ceased and quiet was in a large measure restored.

The sinister fact is only too abundantly supported by evidence to which no one can be blind, that it was not the dreadful and desolating disease, it was not the plague the people feared, it was, on the other hand, the wise and beneficent measures adopted by a parental and civilised Government to deal with it and keep it in check; it was the fear, not altogether unfounded, of having their religious and caste prejudices wounded, their customs disregarded, the seclusion of their inner life invaded and their "pardah" violated.

By simply failing to recognise the real source of danger, the Government appeared to have mined up a sort of Frankenstein's monster. Happily the monster was appeased, but not quite in the way that was expected.

The secrets of the narrow lanes of an Oriental city present a dark and inscrutable problem to the European mind, and it is impossible to comprehend the wild state of ferment which must have prevailed amongst the natives of Calcutta, to urge 200,000 of them to rush forth blindly from the city. Trains and steamers were besieged but were found insufficient, and we read of parties decamping in boats and camping on the banks of the river outside Calcutta. The suffering that such an exodus must have entailed, considering the poorness of the population and the number of helpless women and children, must have been enormous, and behind it all there must have loomed forth the gigantic image of some weighty and indescribable fear.

It is by no means reassuring, or flattering to our system of government, to read in papers, which ought to be well informed upon the subject, that police persecution was one of the evils most dreaded.

There can be no doubt however that there were plenty of scoundrels, who in the dark recesses of Calcutta played upon the terrors of their more simple neighbours, and reaped a rich harvest by their iniquities.

OFFICIAL DIAGNOSIS OF PLAGUE.

It certainly is not flattering to the *amour propre* of Indian medical officials, nor does it redound to the credit of the Government, nor speak much for the interest taken in modern scientific medicine, that in Calcutta, in the capital city of India, there was not a single man who could be relied upon to diagnose definitely a case of plague. In the whole of India there was not a single Englishman deemed competent for this task. So much for the interest taken in, and the encouragement given to, scientific medicine by the Indian Government. Specimens were therefore taken and forwarded to Bombay to Mr. HAFKINE, and for his opinion the whole of India had to wait.

M. HAFKINE declared that he found typical plague bacillus in the specimens sent from Calcutta. Of course owing to want of qualified men this result has not been confirmed, and careful and skillful an observer as M. HAFKINE undoubtedly is, there still remains the possibility of error somewhere, or of chance contamination either in Calcutta, Bombay, or en route.

At such a time we feel keenly the loss of so skilled a bacteriologist as Dr. D. D. CUNNINGHAM, and we cannot understand the delay there has been in filling up his post. It has now been vacant, or as good as vacant, for over twelve months, and the result of such a policy is obvious to everyone.

What is wanted is a man on the spot who can examine cases as they occur, and whose opinion will be accepted without demur. Is it possible that the Government cannot find anyone fitted for this duty out of the whole of the highly trained medical officers of the Indian Medical Service?

As to the accuracy of M. HAFKINE's diagnosis, we have grave doubts, which we have clearly expressed from

the beginning. We have seen a large number of typical plague cases in Bombay, and judging from the clinical aspect of the Calcutta cases, we have no hesitation in expressing the opinion that they are not true cases of epidemic plague.

With reference to "the suspected cases" we saw at the Maniktala Plague Hospital, we have officially reported that they were not plague, and also in the case of Mr. SMITH, the auctioneer, who has been reported to have died of plague, we have the best reasons for knowing that this was not so.

It is familiar to Calcutta practitioners that a form of malignant fever similar in all respects to these stuporous cases is endemic amongst the poorest and worst housed people in Calcutta. Whether the cases that have created such alarm turn out to be anything more than this, remains to be seen. Judging from the course of events, and the small number of persons affected, we think that our doubts on the subject are fully justified.

From all this it appears that from a clinical point of view, we are of opinion that these cases were not plague. M. HAFKINE, from a bacteriological point of view, says they were, and the following question arises, is the mere fact of the finding of this bacillus, sufficient evidence to found a diagnosis of true epidemic plague?

This is a question of the greatest importance and one that no doubt will find an answer before long. Had the matter been thoroughly followed up and investigated by a competent observer, since Dr. SIMPSON reported his cases in 1896, there would be less doubt about it now. Plenty of material exists in Calcutta for such research, and in most civilised countries it would undoubtedly have been undertaken. Yet in such a backward state do we find ourselves, that we are forced to confess that this bacillus may have been in our midst all this time without our being aware of it.

ANTI-PLAGUE INOCULATION.

Inoculation appears to have created quite a scare of its own. It is evidently difficult to understand the native mind and gauge what is going on in it. Inoculation is a new idea, it has taken the native by surprise, and has created a very unpleasant state of excitement, which, we regret to say, has not stopped short of serious crime.

The distinction between optional and compulsory inoculation is not understood. Most things are compulsory to the poor, and the native has seldom any chance of exercising his option.

To be offered inoculation as a substitute for segregation, is very like the famous HOBSON's choice. The fact is so well known that segregation will be resisted at any price, as it was in Bombay, that the offering of inoculation in its place, actually and virtually amounts to the same thing as compulsory inoculation.

It has been proved in so many places that the natives of all classes will eagerly seek inoculation once its advantages have been made clear to them, that it seems the height of folly to suddenly rush it upon them as it were under cover of a threat. This is the way to create alarm, not to inspire confidence.

We have no objection to inoculation *per se*. We regard it as a very interesting experiment, and we have freely published M. HAFKINE's results in our columns and given him all the credit to which we consider that he

is essential. That the method is somewhat crude cannot be denied, but it is equally impossible to ignore the fact that the results have been beyond expectation. We only trust that if this method is to be at last taken under Government patronage, that it will be introduced with every care and precaution, and that the people will be allowed an absolutely free hand in the matter. To make them understand this will be no easy task.

PLAN OF CAMPAIGN AGAINST PLAGUE.

To turn now to the methods to be adopted for the prevention of the spread of the disease. We publish in another place the "Notice" on this subject issued by the worthy Chairman of the Calcutta Corporation, Mr. R. T. GUNN, O.S., who has proved himself a truly large hearted yet firm administrator.

It will be seen that house-to-house visitation and segregation are to form the backbone of the defence; the first has been relegated to the care of Ward Committees, the second has been modified with a view to cause as little irritation to the native mind as possible.

Inoculation is to be the main stand by.

Isolation in hospital is to be enforced only where proper accommodation cannot be obtained in the houses of those affected. While the police are to have no power to examine or remove anyone on their own authority.

It is obvious from this that the policy to be adopted in Calcutta is not a policy of option, it is a policy that has been forced upon the Government, and the only lesson that has been learnt from the Bombay experience, is the inadvisability and even danger of adopting and endeavouring to enforce methods, which are foreign and distasteful to the native mind.

We are glad to see that Sir JOHN WOODBURN, our new Lieutenant Governor, is inclined to yield to native prejudices in every possible manner, and we congratulate him upon this attitude. At the same time it must be remembered that the terms of the Venice Conference form the "*Ultima Thule*," beyond which no yielding is possible. To infringe these would be to inflict ruinous losses upon the whole country.

CLASSICAL PLAGUE PRECAUTIONS A FAILURE?

The Health Officer of Calcutta has published an admirably reasoned note on the subject of prevention of plague in which he shows that the three classical methods of notification, isolation and disinfection, have failed to check plague in India. Notification, he says, must fail because the people will not notify. "The more stringently the measures (of segregation) are enforced the more pains do they (the natives) take to conceal their cases, and even search parties supported by all the powers of the police and military, do not avail to discover more than a moderate proportion of them."

Again he says:—"The conclusion I draw from all this is, that the system of notification, isolation and disinfection has proved, and is bound to prove, a failure in dealing with an epidemic of plague in a city, and that we must look for some other measures which will at least give some prospect of success."

These opinions are looked upon by many as retrograde, and however admirable the reasoning, they do not command themselves to all. We trust the opportunity will not arise of putting them to the test.

THE ANNUAL REPORT OF THE SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA, 1896.

GENERAL REMARKS.

THIS Report is as usual somewhat belated, but considering the large and valuable amount of information it contains, it is perhaps invidious to find fault with it on this score.

The scope of this volume is ambitious, too ambitious it has appeared to us for some time. It purports to give us the complete vital statistics of four distinct classes throughout the whole of India: (1) European Troops, (2) Native Troops, (3) Jail Population, (4) General Population.

The statistics of the first three are reliable, those of the fourth are not. Statistics which are not reliable are useless, yet 140 pages of this Report are taken up with statistics, etc., of the general native population, which, owing to the defective and primitive state of registration of diseases deaths and births, possess no substantial value.

Further, when we consider the fact that the Sanitary Commissioner for Madras, Bombay, etc., each issue separate reports for their own districts dealing with this branch of the subject, and dealing with it in greater detail than the Sanitary Commissioner for India can possibly do, we are driven to the conclusion that the Report before us would lose none of its value, and might even reach us sooner, were all this matter excluded, and complete and reliable statistics only admitted to its pages.

As we move onward, and registration becomes more complete and accurate amongst the natives of India, it is certain that the time will come when a single volume can no longer meet the requirements of such a country as India with its teeming millions, and when more decentralisation will be found absolutely necessary.

Judging from the length of time which it takes to prepare the Report at present, we are inclined to think that that time, if not already here, is at all events near at hand.

THE STATISTICAL MAP.

The first thing to be noticed in the Report for 1896 is that the map, which forms an important feature of these Reports, has undergone an alteration. It has been considerably enlarged, and the boundaries of the geographical groups and sub-groups are now distinctly outlined. The map is, as usual, printed chiefly in different tones of green, and by a curious oversight, which will be no doubt rectified next year, there is nothing to indicate the fact that these tones are used to present graphically the mortality from cholera throughout the country.

This omission might lead us to imagine that the people of Hindustan were the healthiest in the world; for according to the map, the highest death-rate, corresponding with the deepest shade of green, is only 8 per 1,000. When, however, we know that this figure is intended to present the mortality from cholera alone our ideas alter.

GEOGRAPHICAL GROUPS.

These geographical groups are a hideous mistake. The object of this Report is to throw as much light as possible upon disease, no matter from what aspect the subject is approached, not to teach geography.

A more geographical boundary can have no possible connection with any branch of the subject. Climate, as far as we know, is the over-ruling power which stamps its sign manual upon the diseases of a country; these groups or divisions then should be climatic not geographical.

It is many years since Dr. BARNES first started this idea and tried to carry it out; and it is a pity that it has been permitted to lapse into oblivion since his day.

The importance of this matter will be easily grasped when we say that these geographical groups form the foundation upon which all the vital statistics of India are constructed, and the basis of every system of classification.

In some cases these geographical groups correspond fairly well with climatic conditions; in others they are wildly astray. Take group VII, which contains both Karachi and Peshawar. What have these places got in common that they should always be found side by side and the incidence of disease in them tabulated together? On a par with this would be the method of studying epidemiology by mixing up the diseases of Rome and London and endeavouring to trace out some of the laws which regulate epidemics from the result.

On page 45 we have a table showing the incidence of enteric fever in the geographical groups. We take it merely as an example of the fundamental importance given to these groups throughout the Report. We read: "It (the table) shows that groups V, VI, VIII, and XII are especially apt to have high ratios of admission from enteric fever, etc." Considering that, as we have shown, each of these groups may include many different places, differing in toto from each other in all those conditions which may be held to influence enteric fever, and only united by a geographical boundary which is either accidental or purely arbitrary, what real information does such a table give, and what light can it be expected to throw upon the many problems connected with the etiology of disease?

It is a subject of regret that when, as in the present Report, some alterations were made in these geographical groups, they were not altered out of existence, and a more rational division adopted in their place.

METEOROLOGY.

The meteorological data are excellent and ample as far as they go, but we here encounter the same want of system, the same want of a leading idea.

We are given, and have been given for many years, the meteorology of thirty-four stations in India, but upon what system are these thirty-four stations selected?

If it is answered, to instruct readers in the general meteorology of India, we would reply that this is much better done in the Reports of the Meteorological Department.

But no, the object of these meteorological details is, or should be, that they may be readily consulted in connection with the statistics of disease which occupy the greater part of the volume. For instance, supposing any one wanted to demonstrate under what exact meteorological conditions an outbreak of influenza had occurred at some station, it would certainly be very convenient to find all the materials in the same volume, and if the station

was a large and important one, he would naturally be surprised if it was not included in the thirty-four whose meteorology is given year by year.

As it is only the statistics of the troops and jail population which are accurate, the importance of the stations must depend entirely upon the number of the troops or the size of the jail population.

The four following examples will serve our purpose, though they by no means exhaust the list; two are places where meteorology is unnecessarily given; two, on the other hand, are large stations where it is omitted.

We allude to Narayanganj, Sibsagar, Poona and Quetta. In the first there were neither European troops, Native troops or Jail; in the second there were no troops and the average annual strength of the Jail was only 50; in Poona, on the other hand, the average annual strength was as follows:—European troops 2,067, Native troops 2,688, Jail population 1,474, and in Quetta European troops 2,515, Native troops 2,522, Jail population 42.

There can be no doubt on the point, that the meteorology of the last two would be of more interest to the readers of the Report than that of the first two, yet it is the first two that are given. In this matter there is plenty of room for alteration and improvement, as will be readily admitted when we further mention that no meteorological details are given for Rawal Pindi, Umballa or Secunderabad.

ORIGINAL RESEARCH.

The amount of original work carried out under the auspices of the Indian Government is but small, and it is further to be regretted that small as it is, it should be buried in the "Scientific Memoirs by Medical Officers of the Army of India," and not printed in this Report. We say buried advisedly, for few though the readers be who dip into the formidable looking Annual Report of the Government of India, they are probably numerous compared to the fraction who ever see these same "Scientific Memoirs."

We know as a fact that in one at least of the three great libraries in the British Isles, these memoirs cannot be obtained.

STATISTICAL TABLES.

It need hardly be mentioned that the improvements introduced into these latter in 1895 is continued. For completeness, for the amount of information conveyed and for the manner in which it is classified these tables are beyond praise; they are as complete as they could possibly be.

These tables and the meteorology as far as it goes are the most, if not the only, important and trustworthy portions of the Report.

—:—

THE LIFE AND TIMES OF THOMAS WAKLEY, FOUNDER OF THE LANCET.

CERTAINLY not the least interesting portion of WAKLEY'S life is his career as Coroner for West Middlesex to which office he was elected on the 25th February 1880, and which he held until his death—10 years after his Parliamentary career came to a close.

WAKLEY was the first to introduce the notion that the post of Coroner should be occupied by a medical man; in the columns of the *Lancet* he published a series

of articles ably setting forth his reasons for this opinion, and regretting the state of universal and well merited contempt into which the Coroner's court had fallen; at the same time he lost no opportunity of quoting at length all cases that came under his notice in which there was a miscarriage of justice, owing to the want of medical knowledge on the part of the Coroner, who at that time was invariably a member of the legal profession.

Some of these cases form interesting reading, thus in one case where the jury at the express direction of the Coroner returned the pious but meaningless verdict of "Death by the visitation of God" all the evidence pointed to the most human agency in the matter. This was a wholesale catastrophe due to arsenic poisoning.

A family circle having partaken of a particular pie, two died at once, a third some twenty-four hours later, a fourth was exceedingly sick. The remnants of the pie were thrown into the yard, and some fowls who ate it died there and then. The hearing of all this escaped the Coroner, who obtained from his jury the verdict he desired. The bodies were afterwards exhumed and death found to be due to arsenic poisoning.

In another case an inquest was held on the body of a woman who had died from cholera, and the jury under the direction of the Coroner, returned a verdict of manslaughter. The testimony of four medical men, who had examined the body, availed nothing against that of three children, one of whom stated that the deceased was "knocked over" an iron railing, while a second asserted that she was "pushed against" an iron railing, and a third omitting the railing swore that the victim was simply knocked about.

Immediately on entering office WAKLEY, with characteristic energy, proceeded to set his court in order. Every death, the reason of which was not apparent upon the face of its circumstances, was made the subject of an enquiry, and in every enquiry, where the facts required medical elucidation or where the court required medical advice, a qualified practitioner was summoned and, if necessary, a *post-mortem* examination was made.

It was found that the beaules whose duty it was to summon the jury were not above taking bribes to let those able to pay escape the irksome duty of serving; WAKLEY declared that he would not have his court made a mockery by the quality of his juries, so he appointed an officer of his own to replace the beaule and directed him to summon fit and proper persons and take no denial.

Again he was determined that his court should be conducted with decency and dignity; he put a stop to the ribaldry and tipsy familiarity which disfigured the proceedings of many coroners' courts and insisted upon a sober jury as well as a decent one. Counsel, Solicitors, witnesses, etc., were made to understand that contempt of court was as serious a crime before a Coroner as before a Judge or even a Chancellor.

Reasonable as these innovations were, they did not please everybody, and WAKLEY's enemies were not slow to take advantage of the fact. The authorities at hospitals, lunatic asylums, and poor-houses were also opposed to the new Coroner, WAKLEY had been unsparing in his criticism of the administration of these places, and it was feared that he would take advantage of his position to be revenged upon them.

In September 1839, he issued certain instructions to the constabulary of West Middlesex, which roused excitement throughout the country and led to a special meeting of the Middlesex magistrates and later to a Parliamentary inquiry.

We need not further enter into this matter than to say that the tenor of these instructions was entirely misconstrued, and that the result of these enquiries was not only to vindicate his character, but to materially strengthen his position.

The most sensational inquest it was ever WAKLEY's duty to hold was on the body of Private WHITE of the Seventh Hussars, who on June 15th 1848, at the Cavalry Barracks, Hounslow Heath, received one hundred and fifty lashes, administered by two regimental farrars in pursuance of a sentence pronounced by a District Court Martial.

WHITE took his flogging manfully in the presence of his Colonel and Dr. WARREN, the Regimental Surgeon; he then walked to the station hospital, where he remained till the day of his death—July 11th following.

The official report of his death, signed by three Army Surgeons, was as follows:—"Having made a careful *post-mortem* examination of Private FREDERICK WHITE of the Seventh Hussars, we are of opinion that he died from inflammation of the pleura and of the lining membrane of the heart; and we are further of opinion that the cause of death was in no wise connected with the corporal punishment he received on the 15th of June last."

At the inquest it became known that no examination had been made of the deeper tissues of the back. Accordingly it was postponed, and Mr. HORATIO GROSVENOR DAY, a surgeon totally unconnected with the case, was directed to make a further *post-mortem* examination.

Through some misunderstanding, when the court again assembled, it appeared that he had omitted to examine the spine and deep muscles of the back. Accordingly a second adjournment was made, and Mr. (afterwards Sir) ERASMUS WILSON was deputed to perform this task.

Mr. WILSON found the deepest layer of the muscles in a state of pulpy disorganisation. He considered that the pulpy softening of the muscles was due to their excessive contraction during the agony of punishment, and he had no doubt that this was responsible directly or indirectly for the inflammation of the contents of the chest.

It was his opinion that WHITE would have been living had not the punishment been inflicted. He had no doubt whatever on the point.

The result was that the jury found that WHITE died from the mortal effects of a severe and cruel flogging of one hundred and fifty lashes, etc., and added a strong rider urging the abolition of flogging in the Army.

The greatest excitement prevailed on the announcement of this verdict, and soon after reforms were introduced, bearing on the subject of flogging in the Army. So extensive were these reforms that when in 1881 the Army Act formally abolished the practice, few knew that it was still sanctioned by the law of the land.

It is particularly interesting to learn that CHARLES DICKENS once sat on a Coroner's jury under WAKLEY, and has left us his impression of the way in which he performed his duty.

The subject of the inquiry was the death of an unfortunate infant whose mother had committed either murder or the minor offence of concealment of birth. DICKENS was touched by the helpless and miserable appearance of the girl. "I took heart," he says, "to ask this witness a question or two which hopefully admitted of an answer which might give a favorable turn to the case. She made the turn as little favorable as it could be, but it did some good; and the Coroner, who was nobly patient and humane (he was the late Mr. WAKLEY), cast a look of strong encouragement in my direction. I tried again and the Coroner backed me again for which I ever afterwards felt grateful to him, as I do now to his memory." The result was that the conviction was for the minor offence of concealment only.

With DICKENS' estimate of WAKLEY as a Coroner this section of his career fits close. WAKLEY himself would have desired no other critic, and having earned DICKENS' praise would have considered that no higher eulogy could possibly be bestowed upon him.

COMMENTS AND NEWS.

ABUSE OF MEDICAL CHARITIES.

THE Hospital Reform Association, with Dr. J. WARD CUTLER as Chairman of the Council and Mr. T. GARRETT HOBBS as Honorary Secretary, is doing good work in inquiring into, and suggesting remedies for the well-known abuses which exist in connection with hospitals and other medical charities.

At the annual meeting held in London on the 19th January last, it was stated that an Investigation Committee had been appointed to report on the Manchester medical charities. Investigation had been attempted at Brighton but so far it had not met with much encouragement from hospital managers there. The managers of the large general hospitals in London had appointed a committee to draw up a scheme for the better administration of medical relief in the out-patient and casualty departments.

The following recommendations have been adopted by the Committee of the Association :—

RECOMMENDATIONS

1. That in the casualty department of the general hospitals only cases of urgent importance should be attended to.
2. That in the out-patient department patients bringing notes from medical men should have *ceteris paribus* a prior claim to treatment. That a resident physician should be appointed whose duty it shall be to see all out-patients in the first instance and select those that require immediate treatment and decide which do not require hospital treatment. That after patients have received "first aid" their circumstances shall be inquired into by a competent officer. That the honorary medical officers shall not be required to treat more than twenty new cases at one sitting.
3. That the circumstances of all in-patients, with the exception of cases of accident, &c., should be carefully inquired into before admission.
4. That in the case of well-to-do people who are admitted to hospitals in consequence of accidents, &c., the hospitals should have the power at their discretion of recovering adequate fees for attendance.
5. In the case of small provincial hospitals that the plan adopted at the Oldham and Dorchester Infirmaries be recommended for trial.
6. That both in the large general hospitals and in the smaller ones out-patients coming from outside districts should be requested to bring notes from medical men before being treated.
7. In the case of special hospitals (a) that payments by patients should cease; (b) that the eligibility for free treatment should largely depend on the recommendation of private practitioners; and (c) that some provision should be made outside the hospitals for people who are in a position to pay a reduced fee but are not in a position to pay the ordinary fee of specialists.

We think that this Association is deserving of the thanks and support of all private practitioners, and feel sure that in the future it will exercise a large and beneficial influence for the good of the profession.

AMERICA.

As we have before remarked, the question of hospital abuse has reached an acute stage in America, the following resolutions passed by influential bodies may be of interest to our readers as showing the steps that are being taken towards reform in that country :—

BOSTON MEDICAL SOCIETY.

Resolution.

"Whereas, the unrestricted abuses of medical charity in

the great hospitals and dispensaries of Boston is being seriously complained of by a large number of general practitioners; and whereas, the State has granted charters to these hospitals and dispensaries for the definite purpose of giving medical and surgical care and treatment to indigent persons within the city and commonwealth; and whereas, the Boston Medical Society, individually and collectively recognise, with every feeling of sympathy, the rights and just claims of some of our citizens to the benefits of public and private charity, and will not be found wanting in generosity in whatever may tend to foster the moral, social, and physical well-being of the sick, the poor, the destitute, the lowly, the worthy, and the unfortunate; and whereas, large numbers of persons, of both sexes, frequently, daily, and repeatedly receive medical and surgical advice and treatment gratuitously for numerous cases of minor surgery and ordinary illness who are believed to be financially competent to pay moderate fees; and whereas, the time, facilities, and attention at the dispensaries being necessarily limited that which is received by the well-to-do and the undeserving is in that proportion, withheld from those who, by the chartered rules of these institutions, are justly entitled to their benefits; and whereas, the practitioners of medicine and surgery of any community, who have duly graduated from accredited medical colleges, and have incurred the expense of locating in such communities, naturally and justly feel their present and prospective rights and privileges are wrongly encroached upon by the abuses now in practice in connection with medical charities. Therefore resolved, that it is the opinion of this society that some means can be found to check or modify this formidable evil; and, resolved that an urgent call be made upon all such members of the profession who are in sympathy with the movement, and have at heart the best interests of the medical profession, to render such moral assistance and financial support in the adoption of such measures as will tend to eradicate these evils, abuses, and practices.—M. GRABSTEIN, M.D., Secretary."

ASSOCIATED PHYSICIANS AND SURGEONS OF THE CHARITY HOSPITAL, PHILADELPHIA.

At a meeting held on 5th February Dr. SINNICK reviewed the report of the State Board of Charities and showed that during 1897, there were treated at the hospitals and dispensaries of this city 387,417 patients, or about 88% of the entire population.

The following resolutions, were unanimously adopted :—

"Whereas, the abuse of medical charities in the various hospitals and dispensaries throughout the city and State has assumed so great proportions, and has become such an injustice to the actual worthy poor, as well as to the medical practitioner, and

"Whereas, the Philadelphia County Medical Society being the representative body of this city and being, therefore, the most competent to consider the proper action to correct the abuse, be it

"Resolved.—That we request that a meeting of the society be called for the discussion of this subject, to which shall be invited the members of the Board of Charities and Correction, and the Boards of Managers and the trustees of the different hospitals and dispensaries throughout the city, to co-operate in the discussion of the subject, to suggest such legislation as may be deemed expedient, and to formulate a method for the restriction or abatement of the evil.

"Resolved.—That a committee of five be appointed by the President of the Society to present these resolutions to the Philadelphia County Medical Society."

ONE OF OUR MEDICAL HEROES.

The pleasant task of recording the name of PUGNET, a French physician born at Lyons in 1766, from oblivion has fallen to a Russian M. LE POORMENUS SKOKITSCHENKO.

PUGNET received an excellent education, and was first destined for the law, then for the church, finally for medicine. He greeted with enthusiasm the Revolution of 1789, and was unshaken in his attitude towards it, although his father, mother and brother fell victims and he himself was sentenced to the guillotine, the timely death of ROBESPIERRE alone saving him.

Ardent in the cause of suffering humanity he volunteered for service in Egypt, under NAPOLEON.

It was difficult to work while in momentary fear of death, but the young physician knew no fear. PUGNET carried aid to the wounded amidst a shower of bullets with a calmness that was astonishing. The troops retired. PUGNET remained alone, plucking the wounded from the hands of the Mamelukes. NAPOLEON looked on in astonishment.

Plague soon appeared in the army and men died in thousands. PUGNET was transferred to Syria, where its ravages were most intense. The hospitals were overflowing, the sick sought a resting place wherever they could find it, the resources were exhausted, food fell short, the physicians died and the inhabitants fled.

Unaided PUGNET put matters to right and established a provisional hospital in a convent at the foot of Mount Carmel (near the town of Acre). The order to convey the sick to Acre (without any transport being supplied) reduced him to desperation.

Leaving Acre on foot, with his sick, he fell ill on the way but quickly recovered. The epidemic was so severe there that not a single doctor survived.

Fortunately PUGNET was transferred to Cairo, where NAPOLEON had appointed a Commission to inquire into the cause of plague M DESGENETTES, Médecin en-Chief of the Army, aided by NAPOLEON, endeavoured for a long time to conceal the nature of the epidemic. On this account the Commission, which had no doubt on the matter, did not wish to have M DESGENETTES as President.

NAPOLEON at this flew into a passion and upbraided the physician, saying that they would sooner destroy the Army, their country and their fellowmen than renounce a single dogma of their absurd science.

PUGNET alone had the hardihood to stand forth in defence of the honor of the physicians.

This is what he wrote to NAPOLEON —

"M. le Général! Vous êtes conquérant, Vous feignez de vous soucier de la gloire de la patrie, au fond cependant Vous sacrifiez Vous condécroyez à Vos intérêts, à Votre passion insatiable. Vous resterez le même pour toujours. Vous allez dévorer tout ce qui Vous tombera sous la main. Au moins n'offensez pas certaine classe d'hommes, qui n'ont rien de commun avec Vous.

Ils ne désirent pas de gloire à force de violence, ils ont écrit sur leur drapeau l'amour de l'humanité, ils ont consacré leur vie à traiter les blessures que Vous faites Vous autres."

(Sir, you have been victorious in battle, you pretend to care for the interests of your country, in truth however you sacrifice your fellow citizens to your own interests and to your unhealthy passions. You will always be the same. You are destined to destroy everything that falls into your hands.

Spare at least from your reproaches a class of men who have nothing in common with you. They do not desire glory at the cost of violence, they have sacrificed upon their

standard the love of humanity. They have devoted their lives to heal the wounds that you and those like you have made.")

This letter deeply affected NAPOLEON; for he recognized the noble heart of this man and promised him his assistance should he ever require it.

Four years later PUGNET heard of the miserable results to which the French troops in the East Indies were reduced by yellow fever, and all the arguments of his Commanding Officer could not shake his desire to hasten to their relief, being forbidden by his Commanding Officer, he recalled NAPOLEON's promise.

NAPOLEON hesitated to give his consent, but the persevering prayers of this fanatic of self-abnegation gained their end, and PUGNET set off without loss of time.

Death reigned supreme, men in perfect health became sick and died in an hour. PUGNET was attacked, but he was spared, wonderful energy marked his labor on the Island of St. Lucia, and in consequence of the measures he took the epidemic came to an end.

PUGNET had begun a scientific work, but the blockade of the Island by the English brought it to an end. PUGNET was made a prisoner but was soon released.

After so much suffering PUGNET was very well pleased to be transferred to Dunkerque, a small town where he spent his leisure moments in arranging the great mass of scientific materials he had collected. His life was not an idle one; for there were many who sought his assistance or the fruit of his experience, and to assist a fellow creature appealed more to PUGNET than to create a theory, no matter how attractive.

For 17 years he pursued this disinterested course, refusing all recompense and ruining himself by the purchase of drugs for his patients. At the end of this time his spirit was unchanged but his body demanded repose. In 1822 he retired from Dunkerque and settled in Biel. It was in vain that he sought rest, his fame had preceded him.

The sick flocked to him from all sides; this continued for 22 years. In giving counsel to the suffering he forgot his own troubles, and so he continued to receive his patients even on his death bed.

In November 1844, PUGNET, for the first time ceased to receive the sick, but the reason for this was a serious one. PUGNET was dead.

This man who never ceased to render aid to suffering humanity lived 79 years. He assisted thousands in their misfortunes, he restored thousands to life, but . . . they were only men, and with their existence the glory of this grand man passed away.

The author who discovered in the history of medicine so choice an example of the love of humanity and of true self-abnegation, deems it his duty to make it known to the whole world, as a botanist desires to make known some rare plant that he has discovered — (JANUS)

HOW HAFKINE NOBBLED THE CALCUTTA
PLAGUE BACILLUS. WHAT DID HE FIND?

Writing in his excellent journal, our learned contemporary, Dr MAHENDRA LAL SINGAR, M.D., C.I.R., says:—

"It is not a little remarkable that the Health Officer, after making special inquiry into the point, has been unable to trace any connection between the local cases and the arrivals from infected areas, who are kept under observation. It will be remembered that Dr. SIMPSON found his first case in a man recently arrived from Bombay, and this case was satisfactorily shown to be a case of simple vesicular bubo. But now we have cases which are strongly suspected to be cases of plague, and yet none of them could be discovered to

have come in contact with men arrived from Bombay or other infected places. But as M. HAFKINE has pronounced this case to be plague, their origin must be traced to infection from some source or other. And what better source could be found than rats? So the responsibility of introducing plague into Calcutta has been transferred from the shoulders of men to those of rats. 'Rats, however,' says Mr. Risley, 'have been found dead in considerable numbers in the press room of the East Indian Railway and in godowns connected with the coasting trade with Bombay, and it is possible that the infection has been imported by these animals.' We are, however, not told how the said rats could have migrated to the places where the cases occurred unless we are to believe that they infected their brethren in the said places by some sort of wireless telegraphic influence!

"It appears that 'cultures were made from the important organs' of only one case, namely, the first case, after death; and it was upon an examination of these cultures that M. HAFKINE'S opinion was based. It will have to be remembered that these cultures were sent from Calcutta to Bombay, and that they were examined in a laboratory where the anti-toxine serum from plague bacilli are perhaps every day being prepared. We do not say for a moment that necessary precautions were not taken to keep the cultures from external contamination, and that an expert like M. HAFKINE could make any mistake while conducting the examination. But we are bound to say that, considering the vast commercial and other no less vital interests of the metropolis of British India at stake on the opinion pronounced, a sober scientist should have hesitated before passing that opinion from a single instance. And we are bound to say also that Government should have waited for further proof before accepting that opinion as final.

"If Government had not among its numerous medical officers present in Calcutta one single individual competent to make bacteriological examination of plague and other cases, if it had no other person to depend upon in these matters than M. HAFKINE, it should have asked the Professor to come down to Calcutta to make examinations on the spot, so that they might be free from all fallacy. How we miss Dr. CUNNINGHAM at this juncture.

"In reply to the specific question asked by the Hon'ble NARENDRA NATH SEN, the Hon'ble Mr. RISLEY remarked: "Finally, I may explain that the third question asked by the Hon'ble Babu NARENDRA NATH SEN is based upon a misapprehension of the scientific aspects of the question. *Only one plague bacillus is known.* It was discovered almost simultaneously and independently by KITASATO and YERSIN during the Hong-Kong epidemic of 1894. Their discovery has been verified during the present epidemic in India by M. HAFKINE, Mr. HANKIN, various Medical Officers of the Government of India, the members of the scientific missions sent to Bombay by the Governments of Germany, Austria, Russia, and Egypt, and by other foreign scientific authorities. But this bacillus produces three different forms of plague—simple, septicæmic and pneumonic—according as it attacks different parts of the human system. The bacilli discovered by Dr. SIMPSON were not plague bacilli at all. They were common atmospheric bacilli, and Dr. CUNNINGHAM showed conclusively that they did not come from the blood of the persons supposed to be suffering from plague, but were the result of contamination by air.

"It may be true as Mr. RISLEY said that M. HAFKINE Mr. HANKIN, the members of the scientific commissions of various Governments and other scientists, have in a general way confirmed the identity of KITASATO'S and YERSIN'S ba-

cilli. But it is equally true, that the *British Medical Journal*, that CHATA, a countryman of KITASATO, did differentiate the bacilli of the latter from those of YERSIN, and did show his inclination to believe in YERSIN'S bacilli being the pathogenic microbes of plague. *It is also a fact that in plague patients other forms of bacilli than the typical ones described by Kitasato,—forms almost spherical and even chains more or less long,—are not seldom found.* In making bacteriological examination of the contents of lymphatic glands and other organs of the blood, and of the excretions of plague patients, these various forms have to be borne in mind, and we ought to be able to say which form is predominant. Again 'The bacilli found in the blood and in buboes of plague patients are, according to AOYAMA, another Japanese authority, *not identical.* The latter differ in form from the former, and stain by GRAM'S method. According to Dr. BROOKSHANK, —'there is no doubt that the micro-organism which was found in blood is very similar to the bacillus of fowl cholera, and it is quite possible that the so-called plague bacillus is really identical with the bacillus of hemorrhagic septicæmia, and THAT THE REAL NATURE OF THE CONTAGIUM IN SUBONIC PLAGUE IS UNKNOWN.'

We leave our readers to judge on which side the misapprehension lies. Bacteriology is yet in its infancy, and to base the diagnosis of disease on bacteriological evidence alone may be dangerous both positively and negatively. As regards the cases reported by Mr. RISLEY we are strongly inclined to concur in the opinion of the "experienced local practitioner," alluded to by Mr. RISLEY, 'who considered the case (the first one at Kajalitola) to be one of septicæmia of a type known to him as not uncommon in Calcutta.' Indeed, we go so far as to say that if the cases reported were cases of bubonic plague, then we have had the disease long in our midst, and it is necessary, therefore, to have the bacteriological diagnosis of plague thoroughly revised."

THE SYMPTOMS FOLLOWING INOCULATION FOR PLAGUE WITH M. HAFKINE'S PROPHYLACTIC FLUID.

THE *Lancet* (London, 2nd April 1898) says:—"As might be expected, the symptoms following M. HAFKINE'S prophylactic inoculation vary considerably in different individuals. There are many symptoms, however, which are more or less common to all. It would be likely also that the chief symptoms would resemble in a very minor degree those of plague itself. There are, however, symptoms in plague which have no representatives, so to speak, among the symptoms following inoculation. The first indications of systemic affection occur within six hours after inoculation and consist of a sensation of chilliness, with headache, a rise of temperature and pulse, and a general feeling of malaise. There are no local symptoms at first beyond perhaps a slight red blush at the site of inoculation. The general symptoms increase and continue generally for two or three days. Vomiting sometimes occurs and occasionally diarrhoea. The temperature seldom rises beyond 108°F, more frequently it is below 102. Weakness is sometimes very marked and the pulse is feeble. Headache is often very severe. Locally an inflammatory infiltration develops which becomes extremely tender. This extreme tenderness is as characteristic after inoculation as that of the enlarged glands in plague. No enlargement of the adjacent lymphatic glands occurs and only very occasionally does suppuration ensue at the site of inoculation. Desquamation of the cuticle over the inflamed area frequently follows. The local symptoms linger for several days after the patient has apparently recovered his usual health, which is most commonly in from four to eight days. The

local and general symptoms are sometimes very slight, whilst at other times they are not only very severe but last perhaps eight days or more and are followed by considerable weakness.

"The less frequent symptoms, perhaps depending upon personal idiosyncrasy, are very interesting. The minor complaints are joint pains without any swelling, lasting perhaps a fortnight. There is an erythematous rash more or less all over the body and sometimes a distinct urticaria is seen. No papules or pustules have been observed. A certain amount of anaemia and emaciation occurs in a few people, and some complain that they have never felt well since the inoculation. General weakness, loss of appetite, and constipation for some little time afterwards have been more frequently complained of, and a weakness in the lower extremities has been occasionally observed. A few people seem to develop mental excitement and a feeling of uremia; others become irritable in temper for a week or more. Confusion of ideas, a nasty clammy taste in the mouth, and a dry cough lasting for about a week are comparatively common. Nursing mothers have been inoculated without any disturbance to the child and pregnant women have not developed any untoward symptoms. The menstrual period seems sometimes to be anticipated, and if the flow has commenced at the time of inoculation, it is subsequently increased in quantity. Sexual excitement has been mentioned as having occurred in a few cases.

"It is not surprising on comparison with the effects of other toxin feverish attacks to find that certain ailments should be actually improved. Some asthmatic patients seem considerably relieved and even apparently cured for several months by this inoculation. Chronic eczematous conditions, especially in children, appear also to derive some benefit. Some apparently healthy people have even voluntarily stated that they have improved in their general health.

"Such are the symptoms following what is practically a mild dose of the toxin developed by the artificial culture of the plague bacillus. The severer symptoms of plague itself are probably explained by the more frequent and larger dosage of the toxin into the general circulation and perhaps to the actual presence of the bacilli in certain parts. The enlargement of the lymphatic glands so characteristic of plague appears to be due to the presence of the bacillus, as it does not occur after inoculation. Blebs on different parts of the body as well as the cellulitis-infiltration followed by sloughing, both of which are common in plague, have no representative symptoms after inoculation. The so-called pulmonary variety of plague, attended by extensive lobular pneumonia and oedema, with the presence of bacilli in the sputum, is also unrepresented among the symptoms following inoculation. The headache, the irritability, the mental confusion, the chilliness (which in plague itself is a frequently recurring symptom), the vomiting, the joint pains, the weakness, and the general symptoms of adynamic fever which follow inoculation are all prominent symptoms of the disease. The preparation of M. HAFKIN'S prophylactic fluid, as well as the statistics relating to plague inoculation, have been described elsewhere. It is sufficient to state that the dose injected for adults varies from 2.5 to 5 c.c. and for children 0.1 c.c. is calculated for each year of age. If a definite reaction follows one inoculation it is generally considered sufficient, otherwise a second dose is administered after a week's interval. Re-inoculation is almost certainly required the following year, but with a recurrence of the epidemic a shorter interval is imperative. It is unknown how long the protection lasts. As a second attack of plague has in several cases been known to occur within six months,

it would be probably safer for those who are more particularly exposed to the contagion to be inoculated every three months."

PLAGUE OR NO PLAGUE IN CALCUTTA.

WE quote from the *Indian Daily News* the speech of our Editor at the Municipal Council on the occasion of the discussion of the recent Plague Regulations of the Government:—

"DR. WALLACE'S IMPEACHMENT"

"The following is the full text of Dr. WALLACE'S speech at Thursday's meeting of the Corporation of Calcutta:—Dr. WALLACE said: "Mr. Chairman and Gentlemen,—I have listened with attention and interest to the addresses of the Hon. Mr. MITTHER and the Hon. Mr. BANERJI, and I have been much impressed with the earnestness of their appeal to the Government for a due and proper regard for those sacred rites and ceremonies and those religiously guarded sentiments and usages of caste which are so dear to the Hindu and Mahomedan. I am sure I express the feeling of the entire European community when I say that such sentiments have the warmest sympathy of the European community, and that our Hindu and Mahomedan fellow-subjects may always look with confidence to receiving the unanimous support of the European community for the protection of all their social and religious rights and privileges. I feel sure the Government is now directing its policy in regard to its plague regulations with a keen sense of the consideration and respect that are due to the feelings of our Indian brethren, and I hope that nothing will ever be done that will violate the regulations or social ritual of the home life of our Indian fellow-subjects.

"The speakers who have so eloquently dwelt upon these aspects of the Government regulations as they affect our Indian brethren, have rendered valuable services, not only to their countrymen, but to the Government. I have also heard with interest and pleasure what has been said by my learned friend Dr. SANDERS. He scouted the ideas of segregation and inoculation, and he says if the former measure is to be adopted, it should be so carried out that afflicted persons may be accommodated in their own homes under certain precautions. Now it is very gratifying to me to state that the method of segregation, which Surgeon-Colonel SANDERS advocates, was placed before the Bengal Government by the Council of the Indian Medical Association in 1896 at the time of the last plague scare. That body dealt very fully with the whole matter of segregation and represented the lines on which such a measure could be carried out with efficiency, and at the same time obviating all the features that would prove objectionable to our Hindu and Mahomedan brethren. The warning then given to the Bengal Government by the Indian Medical Association has turned out to be prophetically and characteristically true; for had the Government acted on it, our city would not have been devastated of its population by panic. Now, as to the presence of plague in our midst, I for one, with all due deference to the gasetted opinion of the Government, do not believe we have this dread visitor in our midst. I do not believe a single case of plague has occurred. I saw, on behalf of the Municipality, all the cases that were admitted into the Mantala Plague Hospital, and I must admit that after a careful examination of each case, of all of which I have kept notes, that not one of them was a case of plague. I believe contrary opinions have been expressed, but there is the old and unfortunately true saying that 'doctors differ.' Now did not the doctors differ in their opinions regarding the suspected cases of plague that caused the great scare of 1896? You know the story. The same scientist who now pronounces

our suspicion upon a true plague area, and the same in 1885, but then we had rebutting evidence, and the great weight of Dr. OUCHINGHAM's scientific opinion, which saved our city from being pronounced a plague-stricken. Now, however, things are different, we are without Dr. OUCHINGHAM, and among the highly paid, highly educated scientists, whom the Government maintains in the Indian Medical Service, is there not one man in Calcutta who can be pitted against Mr. HAFKIN? So we find the Bengal Government compelled to own its unfitness to give a competent opinion through its own official experts, and it is driven to seek confirmation of its fears from Mr. HAFKIN, a chemist, and not a medical man. We observe to our horror that the fate of our city, its commercial prosperity, are at the mercy of one man's opinion, and it turns out that that man whose interest it is to back up every thing about plague, gives his verdict against Calcutta, and damps us a plague-stricken people. Are we plague-stricken? I venture to say we are not. The Government has been most inconsistent and imprudent in arriving at this unfortunate conclusion. In its regulations it describes plague as a disease having its origin in filth; it says nothing of the plague bacillus. Yet it prosecutes segregation rather than conservancy as the means to eradicate it. It also prosecutes inoculation. Now inoculation is an experimental measure which has not yet reached the domain of scientific certainty. It is quite true that some favorable reports have been made as to its protective efficacy, but a measure of this kind is surrounded with subtle dangers, and should not be boldly and confidently advocated till it has been pronounced safe and useful, after the most extended trial, and after the most unprejudiced enquiry. Before an experimental measure of this nature receives the seal of Governmental approval, and before it is authorised by State orders, it is the serious and solemn duty of the Government to be perfectly assured that the verdict of the medical profession is in its favor and that such verdict is supported by independent, disinterested, and unprejudiced experimenters. I cannot assert that plague inoculation has reached this necessary position of safety. Personally I feel that the people of Calcutta, both Native and European, owe a debt of gratitude to the Bengal Government and to the Chairman of the Municipality for the recent modifications that have taken place in the plague regulations of Government in deference to public opinion in regard to segregation and inoculation, and I believe that if the conciliatory and generous policy of the Government be fully explained to the native population, much will be done to allay panic, and restore peace and order in a city that has had its commercial and social machinery practically paralysed by a little want of prudence and proper consideration of the views of those outside the circle of the Government and its most responsible advisers."

DUTIES OF A MEDICAL OFFICER OF HEALTH.

ART. 13. Quotation from Glen's English Public Health Act of 1875. (Pages 1221 and 1222) says:—"The following shall be the duties of the medical officer of health in respect of the district for which he is appointed—

"(1) He shall inform himself as far as practicable respecting all influences affecting or threatening to affect injuriously the public health within the district.

"(2) He shall inquire into and ascertain by such means as are at his disposal the causes, origin, and distribution of diseases within the district, and ascertain to what extent the same have depended on conditions capable of removal or mitigation.

"(3) He shall, by inspection of the district, both systematically at certain periods, and at intervals as occasion may

require, keep himself informed of the conditions injurious to health existing therein.

"(4) He shall be prepared to advise the sanitary authority on all matters affecting the health of the district, and on all sanitary points involved in the action of the sanitary authority; and in cases requiring it he shall certify, for the guidance of the sanitary authority or of the justices, as to any matter in respect of which the certificate of a medical officer of health or a medical practitioner is required as the basis, or in aid of sanitary action.

"(5) He shall advise the sanitary authority on any question relating to health involved in the framing and subsequent working of such bye-laws and regulations as they may have power to make.

"(6) On receiving information of the outbreak of any contagious, infectious, or epidemic disease of a dangerous character within the district, he shall visit the spot without delay and inquire into the causes and circumstances of such outbreak, and in case he is not satisfied that all the due precautions are being taken, he shall advise the persons competent to act as to the measures which may appear to him to be required to prevent the extension of the disease, and, so far as he may be lawfully authorised, assist in the execution of the same.

"(7) Subject to the instructions of the sanitary authority, he shall direct or superintend the work of the inspector of nuisances in the way and to the extent that the sanitary authority shall approve, and on receiving information from the inspector of nuisances that his intervention is required in consequence of the existence of any nuisance injurious to health, or of any overcrowding in a house, he shall, as early as practicable, take such steps authorised by the Public Health Act, 1875, in that behalf as the circumstances of the case may justify and require.

"(8) In any case in which it may appear to him to be necessary or advisable, or in which he shall be so directed by the sanitary authority, he shall himself inspect and examine any animal, carcase, meat, poultry, game, flesh, fish, fruits, vegetables, corn, bread, flour or milk exposed for sale or deposited for the purpose of sale or of preparation for sale, and intended for the food of man, which is deemed to be diseased, or unsound, or unwholesome, or unfit for the food of man; and if he finds that such animal or article is diseased, or unsound, or unwholesome, or unfit for the food of man, he shall give such directions as may be necessary for causing the same to be seized, taken, and carried away, in order to be dealt with by a justice according to the provisions of the statutes applicable to the case.

"(9) He shall perform all the duties imposed upon him by any bye-laws and regulations of the sanitary authority, duly confirmed, in respect of any matter affecting the public health, and touching which they are authorized to frame bye-laws and regulations.

"(10) He shall inquire into any offensive process of trade carried on within the district, and report on the appropriate means of the prevention of any nuisance or injury to health therefrom.

"(11) He shall attend at the office of the sanitary authority or at some other appointed place, at such stated times as they may direct.

"(12) He shall from time to time report in writing to the sanitary authority, his proceedings, and the measures which may require to be adopted for the improvement or protection of the public health in the district. He shall in like manner report with respect to the sickness and mortality

within the district, so far as he has been enabled to ascertain the same.

"(13) He shall keep a book or books to be provided by the sanitary authority, in which he shall make an entry of his visits and notes of his observations and instructions thereon, and also the date and nature of applications made to him, the date and result of the action taken thereon and of any action taken on previous reports, and shall produce such book or books, whenever required, to the sanitary authority.

"(14) He shall also prepare an annual report, to be made to the end of December in each year, comprising a summary of the action taken during the year of preventing the spread of disease, and an account of the sanitary state of his district generally at the end of the year.

"The report shall also contain an account of the inquiries which he has made as to conditions injurious to health existing in his district, and of the proceedings in which he has taken part or advised under the Public Health Act, 1875, so far as such proceedings relate to those conditions; and also an account of the supervision exercised by him, or on his advice, for sanitary purposes over places and houses that the sanitary authority have power to regulate, with the nature and results of any proceedings which may have been so required and taken in respect of the same during the year. It shall also record the action taken by him, or on his advice, during the year, in regard to offensive trades, and to factories and workshops. The report shall also contain tabular statements (on forms to be supplied by the Local Government Board, or to the like effect) of the sickness and mortality within the district, classified according to diseases, ages and localities.

"(15) He shall give immediate information to the Local Government Board of any outbreak of dangerous epidemic disease within the district, and shall transmit to the Board a copy of each annual and of any special report

"(16) In matters not specifically provided for in this order, he shall observe and execute the instructions of the Local Government Board on the duties of medical officers of health, and all the lawful orders and directions of the sanitary authority applicable to his office.

"(17) Whenever the Local Government Board shall make regulations for all or any of the purposes specified in Section 134 of the Public Health Act, 1875, and shall declare the regulations so made to be in force within any area comprising the whole or any part of the district, he shall observe such regulations, so far as the same relate to or concern his office."

HAFKINE'S INOCULATION FOR PLAGUE.

THE medical profession and the public are alike indebted to Surgeon-Major-General ROBERT HARVEY, M.D., F.R.C.P., for his excellent and impartial Note on HAFKINE'S inoculation for plague. Dr. HARVEY, as Director-General of the Indian Medical Service, made it his duty to inspect the whole of the plague stricken areas of this vast country and to learn by personal observation and enquiry everything that appertained to the causation, spread, prevention and treatment of plague. We publish elsewhere in extenso Dr. HARVEY'S NOTE, from the *Gazette of India*, and we urge upon our readers to peruse it carefully and thoughtfully. Dr. HARVEY, while weighing in detail the important facts which bear upon the scientific aspects of the treatment of various zymotic diseases by a system of inoculation, makes one fact stand out in strong relief, namely, that while scientific research has aimed at preventing and curing such bacillary diseases as diphtheria, tetanus, cholera, anthrax, tuberculosis, &c., time and experience have proved that our endeavours,

though they may have been slightly directed, have proved futile in both prevention and cure. Dr. HARVEY arrays with considerable tact quite a phalanx of statistics in favor of HAFKINE'S method for preventing and curing plague. But every one knows how statistics may appear to prove or disprove anything, but all experimental measures as they affect the prevention or cure of disease conditions, must be judged from numerous standpoints before they can be accepted as either safe or sure. Hence we find General HARVEY states:—

"It must be remembered, however, that all these methods are tentative, that the experiments are only beginning, but the analogies mentioned above, point to the fact that they are experiments in the right direction, and that we may hope for ultimate success."

Mr. HAFKINE himself frankly states that "the process is based on hypothetical considerations, and that time and experiment alone can prove the validity of his conclusions."

Dr. HARVEY further adds:—"It must be obvious that an experiment of this kind must be tried on a large scale before any trustworthy conclusions can be drawn, and that many difficulties and possible sources of fallacy will be met, and must be disposed of, before we are entitled to say that events following inoculations are effects and not sequences." "At present, however, the process is too crude and imperfect to justify any compulsion on the part of Government."

Now in spite of the "favorable reports" concerning HAFKINE'S inoculations for plague, we most emphatically maintain upon the verdict of so careful and exceedingly trustworthy an observer and critic as Dr. ROBERT HARVEY, that HAFKINE'S method is still in the region of doubt and uncertainty, and that the Government is in no way justified in according to it the protection of its authority as a therapeutic agency, either devoid of danger in its consequences, or fraught with any health protecting properties.

In conclusion, we would simply quote here what one of HAFKINE'S warmest advocates, the *Indian Medical Gazette* says of his anti-plague inoculations in its current number, "The danger of drawing too hasty inferences from statistics," says this journal, "has been demonstrated too often to allow us to overlook it here, and, tempting though Professor HAFKINE'S first group of figures are, yet we must bear in mind that they are after all only, as it were, negative proofs of the result, and that the loop-holes of fallacy are both obvious and numerous." Very properly it says that, "as an efficient treatment of recognised value, plague inoculation has yet to prove itself."

ANNUAL REPORT OF THE HEALTH OFFICER OF THE PORT OF CALCUTTA FOR 1897.

WE learn from the Report before us that a good deal of extra work was imposed upon this Department during the year owing to the inspection of all vessels arriving from Bombay, Goa, Jeddah or Kurrachee with the quarantine flag at the fore, in addition to the inspection of all vessels arriving from foreign ports; every vessel that left the port was also inspected.

In this work Dr. FORSYTH was assisted by the appointment of four additional Health Officers, viz., Surgeon-Captains JAY GOULD, B. C. OLDFHAM, F. O'KINALEY, and Dr. C. BANKS.

The health of the Port shows an improvement over the two previous years, the death amongst European seamen being 21.63 per 1,000 against 28.46 per 1,000 in 1896. The death-rate from cholera showed a large decrease, being 9.15 per 1,000 against 16.01 in 1896.

PLAGUE.

One hundred and ninety-four vessels arrived during the year from the plague-infected ports of Bombay, Goa, Jeddah, and Kurrahee, flying the quarantine flag at the fore. None of these vessels had a suspicious case on board.

INFECTIOUS DISEASE ARRIVAL.

The S.S. *Africa* arrived from Rangoon with one case of small-pox on board, on the 16th January 1897. The case was removed to the Campbell Hospital, and the vessel disinfected. Unprotected members of the crew and passengers were vaccinated.

CORPSES AND CARCASSES.

The return furnished by the Superintendent of the Port Police of the number of corpses and carcasses found floating in the river and sunk within the port limits shows an increase. The number of corpses was 167 against 165 in 1896, 135 in 1895, 79 in 1894, and 73 in 1893. The number of carcasses was 2,718, against 2,707 in 1896, 2,216 in 1895, 2,179 in 1894, and 1,932 in 1893.

Five *farrash* boats patrol the river, keeping a look-out for the sinking of all corpses and carcasses they come across.

This matter we learn is to be brought to the notice of the Judicial Department.

We would like to hear a good deal more about these 167 corpses that were sunk in the river during the year.

The gruesome question at once arises—How many of these corpses found their way into the river as the result of foul play? And what steps are taken to ensure a proper investigation of all suspicious cases.

For the police to sink all corpses they come across, without any enquiry, is obviously to put a premium on crime. We would like some assurance that proper supervision and discrimination is exercised in the direction; but we can find nothing of the kind in the Report before us.

SANITATION.

It is satisfactory, almost too much so, to find only one small complaint under the head, *viz.*, that "the channel at Mullick Ghat and the latrines on its banks are not kept in a satisfactory condition," as to who is in default there appears to be a difference of opinion, for the Port Commissioners, although they own the land, say it is the duty of the Magistrate of Howrah to look after its cleanliness. As this matter has been brought to the notice of the Port Commissioners by the Government, we may hope that some solution of the problem will be arrived at.

WHAT SHOULD BE DONE TO PREVENT PLAGUE IN CALCUTTA AND TO SAVE THE CITY FROM RUIN.
